PARTIAL LIST OF CONTRIBUTORS TO VOLUME XXVII

AMES, HERMAN V., A.B., A.M., Ph.D.
Professor of American Constitutional History, University of Pennsylvania
UNITED STATES — THE FORMATION OF STATE CONSTITUTIONS
UNITED STATES — THE PEOPLING OF THE UNITED STATES
UNITED STATES — THE FEDERAL CONVENTION OF 1787

AUSTIN, O. P., M.A.
Statistician, National City Bank, New York
UNITED STATES — TERRITORIAL EXPANSION
UNITED STATES — INDUSTRIAL AND COMMERCIAL DEVELOPMENT

BABASINIAN, V. S., Ph.D.
Professor of Chemistry, Lehigh University
TRINITROTOLUENE
UREA
URIC ACID

BOLLING, GEORGE MELVILLE, Ph.D.
Professor of Greek Language and Literature, Ohio State University, Columbus, Ohio
VEDIC LITERATURE

BOWEN, EDWIN WINFIELD, A.B., A.M., Ph.D.
Professor of Latin, Randolph-Macon College
UNITED STATES — THE ALIEN AND SEDITION LAWS
UNITED STATES — THE LOUISIANA PURCHASE
UNITED STATES — MILITARY EVENTS OF THE CIVIL WAR
UNITED STATES — IMMIGRATION (1789–1916)

BREWSTER, WILLIAM T., A.M.
Professor of English, Columbia University
TRISTRAM SHANDY

BROOKE, TUCKER, M.A., Litt.B.
Professor of English, Yale University
TROILUS AND CRESSIDA
TWO GENTLEMEN OF VERONA, THE

BROWN, MARSHALL S., Ph.B., A.M.
Professor of History and Political Science, New York University
UNITED STATES — STATE CONSTITUTIONS (1789–1919)

BURCH, ARTHUR J.
Secretary of Troy Chamber of Commerce
TROY, NEW YORK

BURR, WILLIAM H., C.E.
Professor of Civil Engineering, Columbia University
TUNNELS AND TUNNELING

CAIRNS, WILLIAM B., Ph.D.
Assistant Professor of American Literature, University of Wisconsin
TWICE TOLD TALES, THE
TWO YEARS BEFORE THE MAST

CALDWELL, JAMES H., B.S.
President of The Ludlow Valve Manufacturing Company, Troy, N. Y.
VALVES

CALLAHAN, JAMES M., Ph.D.
Professor of History and Political Science, West Virginia University
TURKEY, OR THE OTTOMAN EMPIRE, DIPLOMATIC RELATIONS OF THE UNITED STATES WITH
UNITED STATES — HISTORY OF ARBITRATIONS
UNITED STATES — IMPEACHMENT

CARMAN, E. A.*
General, United States Army
TREVILIAN RAID AND BATTLE OF TREVILIAN STATION
TULLAHOMA CAMPAIGN
TUPELO, BATTLE OF
VALVERDE, OR FORT CRAIG, BATTLE OF

CARVER, THOMAS N., Ph.D., LL.D.
Professor of Economics, Harvard University
VALUE

CHADWICK, F. E.
Formerly Rear-Admiral, United States Navy
UNITED STATES — THE WAR WITH SPAIN

COCHRANE, CHARLES H.
Formerly Secretary, Typothetæ of New York
TYPE AND TYPE-FOUNDING

CORNYN, JOHN HUBERT, B.A., LL.B.
Birmingham Southern College
VELAZQUEZ, DIEGO RODRIQUEZ DE SILVA

COUMBE, CLEMENT W.
Editorial Staff of The Americana
UNEMPLOYMENT
UNITED STATES FLYING CORPS
VASES
VAULT
VELLUM

COX, ISAAC JOSLIN, A.B., Ph.D.
Northwestern University, Evanston, Ill.
UNITED STATES — THE PRESIDENT'S OFFICE

CREIGHTON, JAMES E., Ph.D., LL.D.
Professor of Logic and Metaphysics, Cornell University
UTILITARIANISM

* Deceased

Contributors to Volume XXVII — Continued

CROSS, WILBUR L., Ph.D.
Professor of English, Yale University

TROLLOPE, ANTHONY
VATHEK

CURRIER, ANDREW F., M.D.
Mt. Vernon, N. Y.

VACCINE

CUSHMAN, ROBERT EUGENE, A.B.
Associate Professor of Political Science, University of Minnesota

UNITED STATES — THE JUDICIARY

DARTON, NELSON H.
Geologist, United States Geological Survey

UNDERGROUND TEMPERATURES

DAYTON, EDWIN W.
Major, Infantry, R. L.

UNITED STATES — ARMY OF THE UNITED STATES

DEWEY, DAVIS RICH, A.B., LL.D.
Professor of Economics and Statistics, Massachusetts Institute of Technology

UNITED STATES — FINANCES (1775-1919)

DODD, WILLIAM E., Ph.D.
Professor of American History, University of Chicago

UNITED STATES — THE CAUSES OF THE WAR OF 1812
UNITED STATES — THE WAR OF 1812
UNITED STATES — ANNEXATION OF TEXAS TO THE UNITED STATES
UNITED STATES — SECESSION

DOLE, NATHAN HASKELL, A.B.
Editor of Tolstoi's "Collected Works"

TURGÉNIEF, IVÁN SERGÉYEVITCH

DRISCOLL, JAMES F., D.D.
Rector of Saint Gabriel's Church, New Rochelle, N. Y.

TRANSUBSTANTIATION

DRUM, WALTER, S.J., A.B.
Professor of Scripture, Woodstock College, Woodstock, Md.

TRENT, COUNCIL OF

FAIRLIE, JOHN A., Ph.D.
Professor of Political Science, University of Illinois

UNITED STATES — POLITICAL PARTIES

FARROW, EDWARD S., C.E.
Consulting Military and Civil Engineer

TRENCHES

FICKLEN, JOHN R.
Late Professor of History, Tulane University

UNITED STATES — THE CONFEDERACY

FISH, CARL RUSSELL, Ph.D.
Professor of American History, University of Wisconsin

UNITED STATES — THE NEW DEMOCRACY AND THE SPOILS SYSTEM

FLEMING, WALTER L., Ph.D.
Professor of History, Vanderbilt University

UNITED STATES — SUFFRAGE

GARNER, JAMES W., Ph.D.
Professor of Political Science, University of Illinois

TREASON
TREATIES, INDIAN
TRIPLE ALLIANCE
TRIPLE ENTENTE, THE
UNITED STATES — RECONSTRUCTION

GEDDES, JAMES, Jr., Ph.D.
Professor of Romance Languages, Boston University

UN CURIOSO ACCIDENTE

GRAVES, CHARLES, REV.
Minister of the First Unitarian Congregational Society, Hartford, Conn.

UNITARIANISM

GUITERMAN, ARTHUR, B.A.
Author and Critic

TREASURE ISLAND

HANFORD, JAMES H., Ph.D.
Associate Professor of English, University of North Carolina

TRAVELER, THE

HART, ALBERT BUSHNELL, Ph.D., LL.D., Litt.D.
Professor of Government, Harvard University

UNITED STATES — SLAVERY
UNITED STATES — FOREIGN POLICY

HARTMAN, JACOB WITTMER, Ph.D.
Assistant Professor of German Language and Literature, College of the City of New York.

TROTZKY, LEON

HORNER, HARLAN H., A.M., Pd.D.
Dean, State College for Teachers, Albany, N. Y.

UNIVERSITY

HUEBNER, GROVER G., Ph.D.
Assistant Professor of Transportation and Commerce, University of Pennsylvania

UNITED STATES — RAILROAD TRANSPORTATION

INGERSOLL, HELEN
Naturalist

VALLISNERIA

ISAACS, EDITH J. R.
Critic and Essayist

VAN ZORN

JELLIFFE, SMITH ELY, M.D., Ph.D.
Editor, "Journal of Nervous and Mental Disease."

UNCONSCIOUSNESS

JERNEGAN, MARCUS W., Ph.D.
Associate Professor of History, University of Chicago

TREATIES
VAN BUREN, MARTIN

JONES, JENKIN LLOYD, D.D.
Minister of All Souls Unitarian Church, Chicago

UNITED STATES — CIVIL AND RELIGIOUS LIBERTY

KAINS, M. G., B.S.A., M.S.A.
Lecturer on Horticulture, Columbia University

TRANSPLANTING

KEYSER, CASSIUS J., Ph.D.
Professor of Mathematics, Columbia University

TRIGONOMETRY

KINYOUN, JOSEPH J., M.D., Ph.D.
Washington, D. C.

VACCINATION

KLEIN, HENRI F.
Editorial Staff of The Americana

UKRAINE

KLEIN, HENRI F.
McDONNELL, JOHN B., B.A.,
Editorial Staff of The Americana

TURKEY, OR THE OTTOMAN EMPIRE

McCOLLESTER, LEE S., B.D., D.D.
Dean, Crane Theological School, Tufts College, Massachusetts

UNIVERSALISM

McDONNELL, JOHN B., B.A.
Editorial Staff of The Americana

UNITED STATES — NAVY OF THE UNITED STATES

MACE, WILLIAM H., B.L., M.L., Ph.D.
Professor of History and Political Science, Syracuse University

T

TRANCE, a state in which the voluntary functions of the body are suspended and in which a dream life is carried on of more coherency than in ordinary sleep. In some cases the only external sign of trance is the length of time during which the voluntary functions are suspended. The patient is then said to be in a trance-sleep. When the trance is deeper the action of the heart and lungs is very feeble although perceptible; the state of the patient is distinguished as that of trance-coma. When the trance is so deep that the action of the heart and lungs becomes altogether imperceptible, the body falls in temperature and no sustenance is taken, the patient is said to be in a death-trance. There are four definite sorts of trance, each differentiated from ordinary sleep: (1) The subject of a hypnotist or mesmerist, who is controlled to the point of losing consciousness of his surroundings. (See HYPNOTISM). (2) The medium who, according to spiritualistic theories, accepts the control of a discarnate intelligence and goes into a state of greater or less coma, during which he answers questions or has experiences on the astral or psychic plane, of which he is unconscious and cannot remember when he returns to a normal condition. (SEE SPIRITUALISM). (3) The state of an individual who, according to various Eastern philosophies, is able at times to leave his physical body and to travel in his spiritual body on the higher planes of life; or at least who becomes unconscious of activities on the earth plane, resting in a state of coma which his soul or ego has experienced in the world of spirits, spiritual world, heaven-world or whatever one chooses to designate it. Such were the experiences of Swedenborg (q.v.). (4) The condition of the patient who loses physical consciousness but lives and breathes, sometimes for weeks and months. (See COMA). This state is closely allied to somnambulism (q.v.). Consult Podmore, F., 'Modern Spiritualism' (London 1902); Owen, R. D., 'Debatable Land' (1872); Besant, A., 'A Study in Consciousness' (1900); Prince, M., 'Dissociation of a Personality' (1908); Hyslop, J. H., 'Psychical Research and Survival' (1913); Lodge, Oliver, 'Raymond' (1916).

TRANI, tra'nē, Italy, in the province of Bari, on the Adriatic, 26 miles northwest of Bari, a seaport on the southern coast, formerly of considerable importance. The cathedral (12th century) with handsome bronze doors and interesting crypt and castle are the chief buildings. Promenades occupy the site of the ancient fortifications. Trade depends upon oil, grain, almonds, wine and figs. During the Crusades Trani flourished, and it has been the see of an archbishop since the 11th century. Pop. 35,000.

TRANQUEBAR, trăn-kwĕ-bär', India, in Madras, district of Tanjore, 56 miles south of Pondicherry, an important seaport, with citadel and fortifications. There are two Protestant churches, a Portuguese chapel and schools for Danish, English and Portuguese, a reading-room and literary institute. A Protestant mission was established here as early as 1706, which was the first in India. There are some manufactures of coarse cloth. The Danish settlements, established in 1616, were purchased by Great Britain in 1845. Pop. of town 5,000, with native suburb of Poraivar 14,500.

TRANS-ATLANTIC FLIGHT. Up to May 1919 the aerial passage of the Atlantic Ocean was a surmise with a hope of early success, because its possibilities had been worked out, in theory, as beyond a peradventure. The American navy had several sea-planes trained for the endeavor; Capt. Harry Hawker had landed his British Sopwith biplane parts at Mount Pearl, four miles west of Saint Johns, Newfoundland, already on 4 March. On 5 April Captain Raynham and Major Morgan had left Liverpool, England, with their Martinsyde aeroplane and arrived at Saint Johns, Newfoundland. The British authorities had tested their "dirigibles" and *R-34* was expected to sail very shortly.

On 16 May three United States navy sea-planes (*NC-1, NC-3* and *NC-4*) started from Trepassy Bay, Newfoundland, Europeward with the Azores in view as first landing stage. *NC-4* arrived at Horta, Azores Islands, on 17 May under Commander A. C. Read. He had started from Trepassy at 6:07 P.M. 16 May and arrived at Horta 17 May at 9:25 A.M., having accomplished the distance of 1,200 nautical miles in 15 hours and 18 minutes, at a speed of 81.7 knots per hour. *NC-1,* under Lieut.-Commander P. N. L. Bellinger, got caught in a fog just short of the mark and had to be towed to Horta, where the plane sank. *NC-3,* under Commander J. H. Towers, was at first supposed to have been lost, no word arriving as

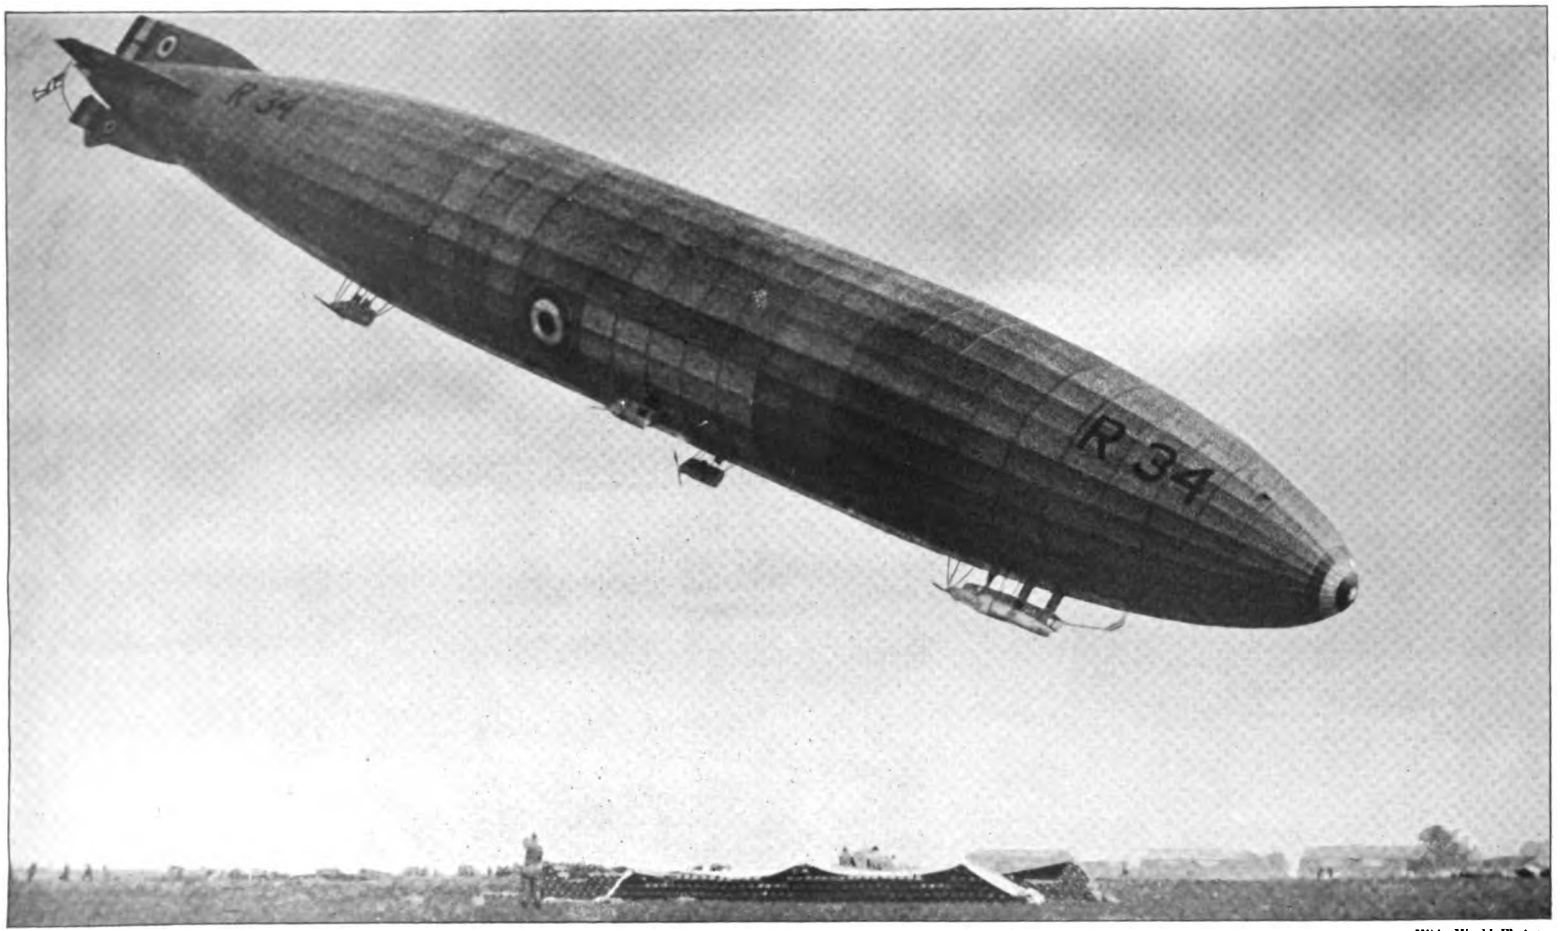
to his whereabouts or existence. But he also had suffered from the fog and, after 48 hours, managed to get to Ponta Delgada under his own power. *NC-4*, on 20 May, continued its flight to Ponta Delgada, leaving at 8:40 A.M. and arriving at 10:24 P.M., accomplishing a flight of 150 nautical miles in 1 hour 44 minutes, a speed of 88 knots per hour; on 27 May the trip from Ponta Delgada to Lisbon was made in 9 hours 43 minutes at a speed of 81.3 knots per hour for the 800 miles; on 30 May Lisbon to Mondego River was negotiated, a distance of 100 nautical air miles, in 1 hour 20 minutes; Mondego River to Ferrol, 220 miles, was the next stage accomplished the same day in 3 hours 7 minutes. On 31 May the final stage, from Ferrol to Plymouth, was accomplished in 6 hours 59 minutes, a distance of 476 miles. Thus the first passage over the Atlantic from the start at Rockaway to Plymouth, a distance of 3,936 nautical miles, was completed in 59 hours 56 minutes flying time. United States destroyers were distributed along the ocean course to give assistance if necessary.

NC-4 Construction.— The extraordinary size of the *NC* flying boats and their general make-up was due to Rear-Adm. D. W. Taylor, chief constructor of the navy. The title *NC* stands for Naval Curtiss and they were constructed for war purposes. The *NC-4* has beneath the flying apparatus a strong seaworthy boat adapted for rough water. The hull is 45 feet long with 10 feet beam. Bottom is a double plank Vee. It is divided by bulkheads into six water-tight compartments, the front one having a cockpit for lookout and navigator. Wings are 12 feet long, weighing but 26 ounces each. There are four Liberty engines of 400 brake horse power per engine and minimum power 1,600 horse power. One of the engines is mounted with a tractor propeller each side of centre line; one engine is mounted on centre line and two others are mounted tandem. The front engine actuates a tractor propeller, the rear engine drives a pusher propeller. It was a new system. Control apparatus was the same as on small aeroplanes. The metal fittings were of special alloy steel, having 150,000 pounds tensile strength per square inch. This permitted much weight reduction. The gasoline tanks (nine of 200 gallons each) were of sheet aluminum, the seams welded; each tank weighed 70 pounds. With its load the machine weighed 28,000 pounds and empty but entire 15,000 pounds. Dimension in length is 60 feet 5½ inches; height 24 feet 5⅛ inches. Personnel of *NC-4* was: Commanding officer, Lieut-Commander A. C. Read; pilots, Lieuts. E. F. Stone and Walter Hinton; radio operator, Ensign H. C. Rodd; engineer, Chief Machinist's Mate E. S. Rhodes.

On 18 May Capt. Harry Hawker with McKenzie Grieve, R.N., as pilot, left Saint Johns with their *Sopwith* and were forced to alight, through engine trouble, in the ocean 1,000 miles east of their starting point and 900 miles from Ireland, their attempted landing point. They were given up as lost for days, but a Dutch tramp steamer picked them up in a sinking condition and landed them. Their plane followed the well-known design of the Sopwith war planes. It had 4 feet width, 31 feet length, tested flight duration 24 hours at 100 miles per hour. Engine was Rolls-Royce developing 375 horse power at 1,800 revolutions. Propeller was four-bladed and geared to 1,200 revolutions. Machine weighed 6,000 pounds fully equipped for the long flight.

On 14 June at 12:13 P.M., New York time, Capt. John Alcock and Lieut. Arthur Brown, pilot, started in their Vickers "Vimy" bomber plane from Saint Johns, Newfoundland, and landed at Clifden, Galway, Ireland at 4:40 A.M. next day, New York time. Mistaking from their height a bog for a green grass land surface, they nearly wrecked their machine on landing, and it buried itself up to the axles and then toppled over on its side. The brave passengers were rescued by landsmen. They had navigated the Atlantic for the first time in a non-stop passage. The wonderful flight was 1,960 miles, and it was completed in 16 hours 12 minutes at the average speed of 120 miles per hour. They had reckoned on the advantage of a full moon, but dense fog and mist obscured both moon and stars for 14 hours, making the voyage doubly perilous. The air was so cold it caked the instruments with ice. Soon after the start the wireless radio apparatus got loose and blew away and their receiver was unable to receive messages either because of "static" conditions. Hence these two brave bird-men and the world were dead to each other 16 hours, adding much to the anxiety of all. But the $50,000 prize offered by the London *Daily Mail* for the first non-stop passage was earned as well as the national greeting. The Vickers "Vimy" plane was motored by two Rolls-Royce engines and was built for bombing. Its wing was 67 feet 2 inches. Length over all was 42 feet 8 inches; gap, 10 feet; chord, 10 feet 6 inches. Gasoline capacity was 870 gallons, weighing 6,000 pounds. The two Rolls-Royce Eagle 375 horse-power engines were carried between the upper and lower planes either side of the fusilage. The strength of the "Vimy" is brought about by hollow seamless tubing in its construction. It had a double under carriage equipped with two-wheel chassis beneath each engine. Entirely equipped full weight was 13,000 pounds.

R-34 Flight.— July 5 Com.-Maj. G. H. Scott, R.A.F., completed his non-stop flight, on the dirigible balloon airship *R-34*, across the Atlantic Ocean by landing at Roosevelt Field, Mineola, Long Island, N. Y. It took 108 hours 12 minutes in its passage from East Fortune air station, near Edinburgh, Scotland. Air distance traveled (as per log) was East Fortune to Trinity Bay, Newfoundland, 2,050 nautical miles (2,357 statute miles); Trinity Bay, Newfoundland, to Roosevelt Field, 1,080 nautical miles (1,242 statute miles), a total of 3,130 nautical miles (3,559 statute miles), regardless of drift from powerful winds. Headwinds and thunderstorms rocked her and lifted her 800 feet one time. Wind was sometimes 50 miles per hour. Shortly before ending her voyage the wind obstructions had so nearly exhausted her fuel as to cause her to send radio calls for additional gasoline, but the wind veered and it became unnecessary. Personnel: Maj. G. H. Scott in command; Capt. G. S. Greenland, first officer; 2d Lieut. H. F. Luck, second officer; Brig.-Gen. E. M. Maitland, executive officer;



Wide World Photos

Arrival of the R-34 at Hempstead, L. I.

Lieut.-Comdr. Z. Lansdowne, United States navy; Maj. G. G. H. Cooke, navigating officer; Lieut. Guy Harris, meteorological officer; 2d Lieut. R. D. Durrant, wireless officer; W. O. W. R. Mayes, coxswain, besides 11 warrant officers and men, six riggers, two wireless operators and a stowaway (Ballantyne), who had been formerly a rigger with the crew and refused to be left behind After several days' stay at Mineola *R-34* returned across the ocean to England (her second passage) without remarkable incident.

R-34 Construction.— The dirigible was of rigid Zeppelin type, built from designs of William Boardmore and Company, Ltd., Glasgow. The machinery was built and installed by Sunbeam Motor Car Company, Ltd., Wolverhampton. She was launched 14 March 1919. Capacity was 2,000,000 cubic feet in 19 gas bags. Length over all, 920 feet. Gross lift, with 95 per cent hydrogen at 15° C. and 760 millimeters barometic pressure, 68 tons. Total horse power 1,375. Speed average, 75 miles per hour. Framework was constructed on longitudinal and transverse lattice girders of duralumin built from three-corner rails and X-shaped pieces. An A-shaped keel at bottom of the hull furnished passage between the cars. The keel contained 81 gasoline tanks of 71 gallons each and storage room for supplies. Sleeping was in hammocks suspended from main ridge of keel. Weight, by tons, carried was: Gasoline (4,900 gallons), 15.8; oil, 0.9; water ballast, 3; crew and baggage, 4; spares, 0.2; drinking water, 0.42. Total, 24.32 tons. Radial wire trusses braced the hull athwartship at the transverse frames, forming the partitions for the 19 gas-bags. Tail planes were horizontal and vertical fins and hinged flaps for steering and elevating. There were four suspended cars: the forward gondola was largest and divided into a navigating room, radio cabin, forward engine-room. The latter contained a Sunbeam Maori-4 engine. The elevating and steering wheels were located in the navigating-room, together with all the navigation instruments (gas-pressure gauges, gas thermometers, level indicators, etc.). There were two small «wing-cars» attached amidships to act as engine-rooms, the after gondola acting in the same capacity. The wing-cars each was equipped with a Sunbeam Maori-4 engine and drove 16-foot propellers (as did the forward engine). The after gondola, of much larger size, had two Sunbeam Maori-4 engines and mounted tandem drove a 19½ foot propeller with either one or both engines. The Sunbeam Maori-4 engines were of special design with 12 cylinders in double row of six each in V-form at an angle of 60 degrees. Cylinders were 110 millimeter bore, 135 metre stroke. The wireless apparatus was 12,000 miles transmission range.

TRANS-MISSISSIPPI EXPOSITION, a popular exhibition of commercial and agricultural products held in Omaha, Neb., from 1 June to 1 Nov. 1898. The exposition covered about 200 acres. There were over 20 buildings artistically grouped and connected by vine-shaded arcades; the main buildings alone having an aggregate floor space of 500,000 square feet, exclusive of 200,000 square feet of gallery space. The exposition was a great success, industrially and financially, the total number of visitors being 2,613,374, and the total cash receipts $1,761,364.18, giving a surplus of $400,000.

TRANS-SIBERIAN RAILWAY, an extensive railroad system of Russia, between Petrograd, Port Arthur (q.v.) and Vladivostok (q.v.), a distance of 5,500 miles across both European and Asiatic Russia. The government of the tsar as far back as 1870 began to plan this great railway enterprise, realizing the possibilities of developing her vast territory to the eastward. Beginning at Moscow the work of building the railroad was rapidly extended and Orenburg was reached in 1877. In 1880 the bridge over the Volga was built and the section connecting the Volga and Obi River basins was begun. In May 1891 the first work on the real Trans-Siberian Railway was begun. From that date the railway was steadily pushed forward. In perfecting this vast enterprise Russia sent commissioners to the United States to study the American railway systems. She imported Italian workmen who had helped to build the Simplon and Saint Gotthard tunnels for the construction work. She built towns in the desert and transported whole families by the thousand to them for the work. Finally the line of track extended from her ancient capital of Moscow in the West to her newest stronghold, Port Arthur, in the East, a direct line of communication — save only for one piece, the Lake of Baikal. This lake is large and frozen nearly half the year. At first it was traversed by boats, but in 1905 a line of rail was laid around its southern end. The line as a single-track railway was completed in 1902. It is 5,500 miles long and cost $175,000,000. The entire system from Moscow to Port Arthur was built cheaply, with light rails and wooden bridges, and it was impossible to maintain anything like a desirable speed. The schedule time for passenger trains was long (13½ miles an hour) for the through express trains. During the Russo-Japanese War it became so apparent that the road was wholly inadequate to the needs of the country that constant improvements of roadway and rolling stock were inaugurated.

TRANSCASPIAN RAILWAY, an important line of railway, beginning at Uzna Ada on the Caspian Sea and extending as far as Merv in 1886, Samarkand in 1888, and to Tashkend and Andijan in 1900. The Amu-Darya (Oxus) is crossed by a wooden bridge 6,804 feet in length.

TRANSCAUCASIA, trans kâ-kā'sĭ-a, Russia in Asia, the region extending between the Caucasus Mountains on the north and Turkey in Asia and Persia on the south. The provinces on both sides of the Caucasus, with the added Armenian districts, constitute Caucasus or Caucasia in the widest sense, and before the empire was broken up were under one central authority, with 11 minor provinces; but the territory is sometimes divided into North Caucasus, Transcaucasia and Armenia. It includes the famous Baker oil region. The chief town is Tiflis. Transcaucasia comprises eight provinces; total area, 95,500 square miles; pop. about 7,500,000.

TRANSCENDENTAL PHILOSOPHY, that type of philosophy which holds understanding to be the creative activity in the real world. To understand the use of the term transcendental during the past century, we must refer back to Kant and his distinction between transcendental and transcendent. Kant applied the term transcendent to such ideas as he believed were beyond the range of any possible experience. On the other hand, he designated as transcendental those elements which were necessary constituents of experience, but which could not come from sense-perception. These transcendental elements are the organizing principles or concepts which are the inherent property of the mind as an active understanding. Such organizing principles could never be furnished by sensation; for it is only by their agency that the material of sensation is built up into a comprehensible experience. Thus Kant maintained that the world of actual experience as far as its form is concerned is the result of the logically necessary structure of our minds, and consequently that this world is formed according to the laws of thought. Just because it is such a thought-construction Kant did not believe that the world of our experience had true reality. This true reality, he affirmed, exists beyond the world of experience and we can know nothing of it except its existence. Thus for Kant the transcendental represented that activity of understanding which is instrumental in the construction of human experience, but not in production of reality. Kant's successors of the Idealistic School (Fichte, Schelling and Hegel) rejected his theory of an ultimate reality beyond experience, and held that the true and only reality was given within the unity of experience. Since the world of experience is formed according to the active principles of understanding, these transcendental principles become, in this case, active not only in the construction of experience, but also in the construction of reality. Thus in the first half of the last century, transcendental acquired a broad and important meaning, signifying in general, a spiritual interpretation of the universe, and more strictly, that philosophy which affirms the activity of reason or understanding in the nature and development of reality. Chiefly through the writings of Coleridge and Carlyle, the ideas of Kant and his successors were made known in England. Through the same medium the transcendental philosophy became known to America and inspired a definite movement in New England. This movement, called New England Transcendentalism, was a reaction from the prosaic orthodoxy and utilitarianism of the time toward a deeper and more ideal interpretation of reality. W. E. Channing and Ralph Waldo Emerson (qq.v.) were prominent in the inauguration of this movement; and there became associated in it a remarkable coterie of congenial spirits. The Transcendental Club, founded in 1836, and Brook Farm (q.v.), a social community organized in 1841, were immediate results of the movement. The first literary organ of the school was the *Dial,* founded in 1840. The *Journal of Speculative Philosophy,* founded in 1871, and the Concord School of Philosophy (1879) were later expressions of the same. The philosophy of this school was not systematically set forth, nor was it derived wholly from German sources. It was an idealism, rather vague, and often incoherent, which owed almost as much to the philosophy of Plato and the Neo-Platonic mysteries as to modern thought. Abolitionism and philanthropy owe much to the New England Transcendentalists. See ALCOTT, A. B.; HEDGE, F. H.; OSSOLI, SARAH MARGARET FULLER, MARCHIONESS; RIPLEY, GEORGE and THOREAU, H. D.

TRANSFUSION, *in medicine,* the operation of transferring blood (defribrinated) from a receptacle to the vein of a patient — indirect or mediate transfusion; the transmission of blood from the vein of the giver to that of the patient — direct or immediate transfusion; also the intravenous or subcutaneous introduction into the body of any substance, as saline solution, etc. The transfusion of blood from the veins of one living animal to those of another, or from those of a man or one of the lower animals into a man, is a very old operation, having been first performed in 1492. Although it has been used many times with success in restoring the vigor of exhausted subjects, it has frequently failed, owing to the injection of air, the too rapid distention of the heart, phlebitis, thrombosis and embolism. Blood-transfusion has been mainly used in cases of exhaustion from hemorrhages. In recent years the tendency among medical practitioners has been to substitute the injection of normal salt-solution for that of blood. It seems to be proved that "for efficiency, freedom from danger and ease of administration the subcutaneous injection of normal salt-solution, six drams of sterilized salt to one gallon sterilized water, at a temperature of from 110° to 120° F., excels any and all things that have ever been used to relieve those suffering from shock and from the effects of hemorrhage, and as an eliminant in septic and toxic conditions." The possible dangers at-

tending the intravenous injection of normal salt-solution are those of blood-transfusion; but «when life is almost extinct and the patient's vitality so low that the probability of absorption from the subcutaneous spaces is slight, or where the tissues are œdematous, then the solution should be injected into a vein.»

TRANSITS. The passage of a heavenly body between the observer and another more distant body of larger apparent surface is called a transit. The most frequent phenomena of this kind occur in the case of the satellites of Jupiter. The latter is many times larger than any of its satellites and it happens very frequently that an observer with a good telescope can see the passage of a satellite of Jupiter passing over the disc of the planet. The times of these transits are predicted in the astronomical ephemeris. The transits of the inner satellites occur at nearly equal intervals of one day 18½ hours, and it takes about 2 hours and 27 minutes for the satellite to cross. The transit can be observed only when Jupiter is above the horizon and the sun below it, so that only about one transit in five is visible at any one place. Since the satellite is an opaque body, it casts a shadow which may be thrown upon the planet. To an observer on the latter, if the shadow passed over his position, there would be a total eclipse of the sun. The shadow appears to us as a small dark spot passing over the planet near the position of the satellite.

The satellites of all the other planets are either too small or too distant to admit of their transits being observed. For the most part they are entirely obliterated to our sight by the brilliant light of the planet itself when they approach the latter.

The planets Mercury and Venus, having orbits inside that of the earth, will be seen in transit across the sun whenever they pass in a direct line between the earth and sun. If the planes of their orbits coincided with the ecliptic, this would happen at every inferior conjunction of the planet. But, as a matter of fact, there is a certain inclination of each of the orbits to the ecliptic. Imagining the latter plane to surround the sun, extending out to the earth, the orbits of the inferior planets each intersect this plane at a small angle at two opposite points. The line adjoining these points passes through the sun and is called the line of the nodes. If, when the planet is in inferior conjunction, the earth happens to be on or near this line, a transit of the planet will be seen across the sun's disc. In the case of Mercury the earth passes the line of nodes about 8 May and 10 November of each year. It is only within a few days of these times that transits of Mercury can be seen. When such a transit does occur, we must generally wait several years before there is another. The interval between those which occur in November is generally 7 to 13 years. The interval between the transits which occur in May is generally 13 or 20 years. The following is a list of the transits of Mercury for the 20th century with the Greenwich mean time of the middle of the transit:

Year	Date	Greenwich mean time
1907	Nov. 14	0 h.
1914	Nov. 7	0
1924	May 7	14
1927	Nov. 9	18
1940	Nov. 11	11
1953	Nov. 14	5
1957	May 5	13
1960	Nov. 7	5
1970	May 8	20
1973	Nov. 9	23
1986	Nov. 12	16
1993	Nov. 5	16
1999	Nov. 15	9

The earth passes the line of nodes of Venus on 6 June and 6 December of each year. But it very rarely happens that Venus is so near the node on these dates that a transit will be seen. Accordingly the transits of this planet occur at much longer intervals than those of Mercury. For many centuries past and to come there are four transits in every 243 years. The condition which governs their recurrence is that 13 revolutions of Venus require almost exactly eight years. The result is, when Venus and the earth happen to pass a node at nearly the same time, they will both pass nearly the same point eight years afterward. But at the end of the second interval of eight years the conjunction will occur so far from the node that no transit will be visible. The result of this is that the transits occur in pairs, eight years apart. The interval between the last transit of one pair and the first of a pair following is either 105½ years or 121½ years. The dates of these transits for several centuries past and to come are as follows:

1631 December 7	1882 December 6
1639 December 4	2004 June 8
1761 June 5	2012 June 6
1769 June 3	2117 December 11
1874 December 9	2125 December 8

It will be seen that the whole 20th century will pass away without the inhabitants of the earth having an opportunity to observe this phenomenon. But the approach of the transits of 2004 and 2012 can be watched in thought through successive cycles of eight years. An inferior conjunction of Venus occurred on 8 July 1900. At that time the earth, having passed the node on 5 June, was 34 degrees distant from it. In consequence, there was no transit, but Venus, could it be visible so near the sun, would have been seen passing below the sun. Eight years later the same thing will repeat itself, only the conjunction will take place between two and three days earlier, namely, on 5 July 1908, the earth being between two and three degrees nearer to the node than it was on 8 July 1900. The conjunction will go on repeating itself in 1916, 1924, etc., two or three days earlier at each repetition and a little nearer to the node, until 2004, when there will be a transit. At the conjunction of 1908, the earth will be on the opposite side of the node, but

near enough to it for another transit. Then there will be no more transits for more than a century.

Transits of Venus derive their astronomical celebrity from the belief entertained in former times that they afforded the best method of measuring the distance of the sun from the earth. The measures were made by the principle of parallaxes. An observer, as far north as he could station himself to observe the transit, would see Venus pass over the sun's disc on a line apparently further toward the south than an observer who was in the Southern hemisphere. The comparison of the observations made by observing the times which, at each station, it took Venus to complete its transit, afforded the means of calculating the parallax and the distance of the sun. The feasibility of doing this was pointed out by Halley about the middle of the 17th century, and, on his proposal, expeditions were sent by various nations to points in the Northern and Southern hemispheres to observe the transits of 1761 and 1769. This was a period of great unrest, and several of the expeditions became celebrated through the adventures to which they gave rise. In 1769 Mason and Dixon, the English astronomers, started on a ship of war for their station in the Southern hemisphere, but were attacked by a French frigate and were compelled to return to port after a severe battle. The king of Denmark sent Father Hell, a Jesuit astronomer of Vienna, to a point near the North Cape, where very successful observations were made. But doubts were thrown on the genuineness of his record, which were not settled for more than a century. The transit of 1769 was visible in the Atlantic States and observations upon it were made under the auspices of the American Philosophical Society, held at Philadelphia. The most celebrated of the Philadelphia observers was David Rittenhouse.

When the observations of these transits were worked up, it was found that they would not give so certain a result as was anticipated. No two observers seemed to agree as to the exact moment at which Venus had entered wholly upon the disc of the sun. The entrance was not seen in the sharp and precise way it should be seen, but seemed to be uncertain, through a dark haze forming on the two limbs at the moment when Venus was entering. The outcome of the affair was that it was more than 60 years after the last transit before a result had been worked up from it which was supposed to be quite satisfactory. This was done by Encke in 1822. The distance of the sun which he derived was, in round numbers, 95,000,000 miles. This distance appeared in all astronomical textbooks and was almost uniformly accepted for 30 years.

Then it was found by Hansen and others that there was something wrong in this determination and it was claimed that the distance was more than 3,000,000 miles less than Encke had found it. The methods of making this determination are stated in ASTRONOMY, THEORETICAL. It has since been shown very clearly that a great error did really exist in Encke's determination, though it was not so great as had at first been supposed.

Notwithstanding this failure of the method, it was supposed that with the greatly refined telescopes and better means of observation of recent times, the transits of 1874 and 1882 could be utilized advantageously in the same way. Accordingly, on each of these occasions, expeditions, fitted out with the best instruments that science could provide, were sent by various nations to the best stations for observation in various parts of the world. But when the observations were worked up, the results were again found to be unsatisfactory and the observations turned out to be more useful for determining the position of Venus, and the slight change from century to century of its node, than for determining the distance of the sun.

SIMON NEWCOMB.

TRANSMIGRATION OF THE SOUL, or **METEMPSYCHOSIS,** the belief of many races and tribes at all times, to the effect that the soul after the death of the body passes into the bodies of the lower animals or other human bodies, or, it may be, of plants or inanimate objects. Among various tribes of Africa and America the belief is found entirely unconnected, so far as can now be discovered, with any ethical notions. In the teaching of the Brahmanic Hindus, among whom the doctrine can be traced further back than in any other race, it has its foundation in the belief of the connection of all living beings and of the gradual purification of the spiritual part of man and its return to the common source and origin of all things — God. By some the migration of a human soul through various bodies is regarded partly as a penance and partly as a means of purification. E. B. Tylor says in 'Primitive Culture,' that "the theory of the Transmigration of Souls, which has indeed risen from its lower stages to establish itself among huge religious communities of Asia, great in history, enormous even in present mass, yet arrested and as it seems henceforth unprogressive in movement; but the more highly educated world has rejected the ancient belief and it now only survives in Europe in dwindling remnants." Probably the greatest intelligence who believed in metempsychosis was Plato. The doctrine was and is common in Asia and was accepted by some of the early Christians, and there are suggestions of it in the Kabbala.

Pythagoras is the first Greek philosopher in whose system the doctrine occupied an important place, but Thales and Pherecydes are both said to have preceded him in teaching it. Plato in his 'Phædo' advances some probable arguments in favor of the doctrine, propounding the speculation that souls return into the Godhead after a cycle of 10,000 years, during which they have to abide in the bodies of animals and men. Plotinus treats of two kinds of transmigrations, a passage of souls from invisible ethereal bodies into earthly ones and from earthly into other earthly bodies. Among the Romans, Cicero alludes to this doctrine, and Virgil, and more especially Ovid, in many passages give it a poetical treatment. Cæsar informs us that it was believed in by the Gauls, who, he says, in this faith were able to despise death. The doctrine is also found in the Talmud, but only a minority of the Jewish rabbis appear to have adopted it. They treat the sub-

ject of transmigration in their peculiar way, maintaining that God created but a certain number of Jewish souls, which, therefore, constantly return on earth as long as Jews are to be found here and are sometimes made to dwell in the bodies of animals for the sake of penance, but at the day of the resurrection will all be purified, and in the bodies of the just revive on the soil of the promised land. The doctrine of the transmigration of souls has also been held by various Christian sects, for example, by the Carpocratians, Valentinians and Manichæans. It was also professed by the Arabs before Mohammed, but was not admitted by him into the Koran. Even some modern European writers have inclined to this doctrine. Among these may be mentioned Lessing in Germany and Pierre Lerou and Jean Reynaud in France. The reasoning of Lessing in support of the doctrine amounts to this, that the human soul can acquire the infinite conceptions of which it is capable only in an infinite series of successive existences, that the soul in one condition may supply the deficiencies of another, and thus gradually fit itself for a perfect life.

He thus appears more of a reincarnationist, and this emphasizes a distinction that many lose sight of. Reincarnation and transmigration are not at all identical. Obviously all human intelligences have a conscious ego which the majority conceive to be an immortal soul. Whatever we call it, we have something that raises us above the animal body which we inhabit. This soul or ego comes from somewhere or is created when each of us is born. Inasmuch as some souls very early show vast abilities and others are very dull and stupid, the assumption that the wise souls have lived before is not irrational. This being granted, we have our choice of two momentous but quite different theories. Transmigration supposes that the soul at death goes into another body, perhaps the body of a beast if punishment is deserved, perhaps is born into a wealthy and brainy family if reward is deserved. Reincarnation, as generally taught and accepted by Theosophists, is but one day in a larger life; it propounds that as individual souls die here they pass a time on the higher planes, and are then reborn to acquire further experiences, advancing or evoluting from the lower to the higher. This is an extension of the idea of evolution and far more reasonable than the transmigration doctrine. Many, therefore, regard transmigration as a mere corruption of the rational theory of reincarnation. Consult Besant, A., 'The Self and Its Sheaths' (1895); Sinnett, A. P., 'Esoteric Buddhism' (1883); Berthalet, A., 'Transmigration of Souls' (1909); Moore, G. F., 'Metempsychosis' (1914); Muller, Max, 'Six Systems of Indian Philosophy' (1899).

TRANSMISSION OF POWER, Long Distance. See ELECTRIC TRANSMISSION OF ENERGY; POWER TRANSMISSION.

TRANSPADANE (trans-pā'dān) **REPUBLIC.** See CISALPINE REPUBLIC.

TRANSPIRATION, *in physics and chemistry,* a name first applied by Graham (in 1846) to the phenomena that are observed when a gas discharges into a vacuum, through a capillary tube, and since extended so as to include the passage of any kind of a fluid, whether gaseous or liquid, through a capillary tube, from a region where the pressure is high, to one where it is low. The laws governing the transpiration of fluids are imperfectly known. They are quite different from those that govern diffusion phenomena, and also different from those that hold in the case of the *effusion* of gases through a minute hole in a thin partition. In transpiration, the viscosity of the fluid appeared to be the chief factor in determining the quantity of fluid traversing the tube in a given time. The temperature of the fluid is also of much importance. Water, for example, will transpire through a given tube two and a half times as rapidly at 113° F., as at 41° F., the conditions of the experiment being supposed to be identical in all respects save as to temperature.

TRANSPLANTING, the process of establishing plants in new quarters, is one of the most important operations of horticulture, agriculture and forestry since it permits large numbers of plants to be grown during their early stages in very restricted areas, thus economizing space and the labor entailed in their cultivation until they are able to care for themselves. The operation is, therefore, in constant use in greenhouses, nurseries, etc., where it occupies a very large part of the time of the workers. And for forestry work hundreds of thousands of seedling trees are transplanted annually.

The operation may be performed at any season provided proper care is exercised in manipulation. But there is with each species of plant a season at which success is more certain than at others. With evergreens this season is in the spring just before growth starts; with deciduous subjects the autumn, after the leaves have fallen, is often as good as the spring, but a great many deciduous plants may be transplanted during the growing season. Usually, and upon large scale operations, however, only small herbaceous plants are transplanted while in active growth and then only when prepared for such operation by being grown in gardens or beds with this end in view. Such preparation is necessary since the operation, so far as the plant is concerned, is always violent because, even when most carefully performed, large quantities of the roots are destroyed and these losses are the greater as the plants are larger and more firmly established. Hence, the smaller the plant when removed, the more likely is it to become re-established. Trees, shrubs and herbaceous perennials which have not become active in the spring or have ceased activity in the fall are less likely to suffer because their active roots have either not formed, as in the former case, or have ceased to act in the latter. The plants should always be removed with as much of the root-system as possible, be exposed to the air and sun as short a time as possible and replanted in soil at least as moist as that from which they have been taken; if more moist, so much the better. By soaking the soil deeply around each plant it is possible to transplant strawberries and other plants successfully even while the ground is powdery dry in midsummer. Since the loss of feeding roots will curtail the supply of water

absorbed, the leaf surface must be reduced considerably. In many instances one-half is considered satisfactory, but with fruit trees, vines and ornamental shrubs, two-thirds or even more is frequently cut away from the tops. This top pruning is preferably done after the plants have been set, because any injured twigs may then be removed and there is then less danger of injuring the buds which are counted upon to form the new tops. Always the soil should be pressed firmly about the roots, the larger subjects being made firm by tramping the soil down hard with the feet.

Many factors exert an influence upon transplanting. In arid regions, and in places where the winds are dry or prolonged, the operation is less successful than where reverse conditions prevail. Plants which have tap-roots cannot usually be transplanted successfully after they have once become established; hence, the necessity of transplanting them when very small and the advisability in many cases of cutting off the tap-roots by means of root pruning tools which go beneath the plants while still growing in the nursery rows. Instead of this method plants and others that are slow to produce roots are often transplanted several times in the nurseries to develop more extensive root-systems near the surface. Stocky plants almost invariably give better results than attenuated or weak ones, and plants which have been inured to the temperature of the outside air succeed where plants not so "hardened-off" from greenhouse or hotbed conditions will almost invariably fail or suffer serious check. The weather at the time of the operation is also an important factor. If cool, cloudy or showery weather succeeds the transplanting, the chances of success not only in the operation but in the crop (if the plant is an economic) are greatly enhanced, and if the soil be freshly prepared so much the better. Except in dry weather it is inexpedient to water newly set plants; but when this is done water should be given in abundance at the base of the stem, and after it has soaked down the surface should be pulverized to hold the moisture in the soil. The watering is best done in the evening and the pulverizing in the morning.

For the transplanting of cabbage, tomatoes, sweet potatoes, strawberries and other field-crops special machines have been devised. They usually consist of a furrow-maker, a distance-indicator, a plant-setting device, a tank for watering the individual plants as set, and two seats for the boys who place the plants alternately as needed. The whole is mounted on wheels and drawn by a pair of horses. The position of the next row to be planted is indicated by a marker. These machines are widely used and have been found to do excellent work with great rapidity and economy. The "misses" and failures are surprisingly small in number. They are economically filled by hand.

The transplanting of large trees is frequently practised for producing quick effects in parks and private estates. The subjects chosen are always such as have grown remote from other trees, first because the labor of cutting roots is less, and second because the tree is more shapely. Trees which have grown in groves and forests are rarely selected because their trunks are frequently too long, and have to be easily handled to be sightly when transplanted as isolated specimens. The lower and the more bushy the top the better, because the mechanical appliances required are less powerful and costly and because the necessary pruning of the top after setting can be done with least injury to the form of the tree. If such trees may be obtained from shallow soil, so much the better, because the roots will then be near the surface. Trenches are dug as far away from the trunk as seems advisable, with large specimens 15 feet or more radius is common. When the work is done during the growing season the roots exposed are wrapped with wet moss, straw or similar material and burlap. They are wrapped and tied to the trunks for ease of handling in transit. The tree is lifted upon trucks after the excavation beneath it is complete and the ball of earth with the roots is transported to new quarters. In winter work with large trees the trenches are dug if possible in the fall and the tree with its ball of earth lifted when frozen. The practicable limit of weight for such specimens seems to be about 30,000 pounds. Such specimens of maple, elm and other hardwood trees have a diameter of about two and one-half feet. When being set in its new position the earth should be shoveled in gradually after the roots are in place and abundant water be applied to ensure the complete filling of every cranny. Tamping the soil around the roots with small rods is also widely practised. It is doubtful if such operations are in the long run entirely satisfactory when considered in the light of the expense, but as in the case of ordinary transplanting necessity demands them. Consult Bailey, 'Standard Cyclopedia of Horticulture' (New York 1914–17).

M. G. KAINS,
Horticultural Consultant.

TRANSPORT, a ship or vessel employed by a government for carrying soldiers, war stores or provisions from one place to another. At the beginning of the Spanish-American War the United States had no ships of this class. A number of coastwise craft were purchased and hastily transformed into transports on which troops were shipped to Manila and other points. When the war closed the United States government fitted up a number of these vessels as model transports. In the war between Russia and Japan in 1904, the Japanese transported almost their entire army to Korea; some of her expeditions requiring as many as 100 transport ships for this purpose. When the United States declared war against Germany in 1917, it was almost wholly without efficient transports, for all available vessels had been put into service transporting freight, there being a reduced supply of ocean-going vessels. The first step of the United States government, therefore, was to overhaul the German ships that had been interned in Hoboken, and fit them for transport service. The government then bought all available merchant craft, which were few, and started its immense shipbuilding program, which was one of the wonders of the war. (See SHIPBUILDING). The United States transports sailed regularly from various ports, always unannounced, and so effectively guarded that there were very few losses in landing millions of troops in France.

TRANSPORTATION, (1) a punishment formerly awarded in Great Britain for crimes of a serious description, but not entailing the penalty of death. It varied in duration from seven years to the term of the criminal's life, according to the offense. The convicts were sent to Australia, Tasmania and Norfolk Island. In 1857 transportation was superseded by penal servitude, but it was only in 1868 that transportation to western Australia actually ceased. (2) A general name for the movement of passengers or freight from one point to another, by rail, road or water. Transportation will be found fully treated in various articles under RAILWAYS: AMERICAN MERCHANT MARINE; COMMON CARRIER; STEAM VESSELS.

TRANSPORTATION OF SCHOOL CHILDREN. See EDUCATION, RURAL.

TRANSUBSTANTIATION. The real substantial presence of the body and blood of Christ in the Eucharist is one of the fundamental doctrines of the Roman Catholic Church, and the mode or nature of this mysterious presence, which is also a matter of doctrinal belief, is expressed by the technical theological term "Transubstantiation." The word seems to have been first used by Hilbert, bishop of Tours (1057–1134); it afterward became current in the Scholastic period and was solemnly adopted and approved by the Council of Trent (Sess. 13, Can. 2). In controversy exception has been sometimes taken to the term as being unscriptural and relatively new, but the real issue is concerning the doctrine that it serves to express, for if the traditional Catholic belief in the Real Presence be true — belief which was never seriously called in question before the Sacramentarian controversy of the 16th century — it must be granted that considering the system of philosophy according to which the entire scheme of scholastic theology was built up, no more appropriate word could be found to convey the idea than "Transubstantiation." as is shown by the use of the cognate words transformation, transfiguration, etc. Like the words ὁμοούσιος and θεοτόκος which in earlier controversies became famous as epitomizing the specific points of doctrine in dispute, the term "Transubstantiation" embodies the distinctive teaching of the Roman Catholic Church concerning the mystery of the Eucharist. In defining the traditional position on this point against the various new views advocated by the Reformers, the Council of Trent (Sess. 13, ch. 3, 4 and Can. 2)* describes transubstantiation as "the changing of the whole substance of the bread into the body, and of the whole substance of the wine into the blood of Jesus Christ, the appearances of bread and wine alone remaining." This doctrine, as explained by theologians, involves the Aristotelian and scholastic theory concerning the physical nature of bodies. These are supposed to contain two distinct and even, absolutely speaking, separable elements, namely, the underlying substance, and the accidents by which the substance is variously modified (for example, size, shape, weight, color, taste, etc.). Substance, according to the same theory, consists of two essential elements or principles, one passive and indifferent, called the matter (*materia prima*), the other active and determining, called the substantial form. The matter is supposed to be the same in all bodies, and the specific nature and characteristics of each one are determined by its form. Thus, every species of body inanimate or living, including man, has its own substantial form whereby it is specifically constituted, and differentiated from all other species, and when one substance or body is changed into another (for example, wine into vinegar), the process is understood by the Scholastics as the passing away of one form (that of wine) and the succession of a new one (that of vinegar), while the material element which is the subject or basis of the change remains the same. This substantial change is, therefore, technically called transformation. No process of natural change from one thing to another was supposed to involve both elements of substance (matter and form), but such being the miraculous change recognized by tradition and the theological schools in the mystery of the Eucharist, it was aptly termed transubstantiation. According to this doctrine, in virtue of the divine power attached to the words of consecration, the entire substance (both matter and form) of the bread and wine ceases to exist, and its place succeeds that of the body and blood of Christ. The accidents or appearances remain as they were before, but they do not adhere to or modify the body of Christ as they did the substance of the bread; they are sustained miraculously without any connatural subject of inhesion, and in all respects they follow the same physical and chemical laws as if no change whatever had taken place. The body and blood of Christ remain present in these conditions as long as the consecrated species retain the outward appearance and characteristics of bread and wine, but when through deglutition or otherwise these qualities disappear, the Real Presence ceases, and the matter of that substance, which if the process were merely natural would, in the given conditions, have succeeded the bread and wine, is created to meet the exigencies of the new accidents which supervene. Hence the doctrine postulates a real annihilation of matter and a subsequent creation of the same. Besides this the Real Presence thus explained, involves various other miracles, for instance, the multilocation of Christ's body in the Sacrament and its presence in the consecrated particle without the ordinary relations to space — a presence analogous to that of the soul in the body which it animates, but which is not really measured by any corporeal dimensions. In explanation of this the theologians say that Christ's body in the Sacrament retains its internal, intrinsic dimensions, that is, the mutual relation of the different parts to one another, but is deprived of its extrinsic quantity, that is, its relation to other physical objects and surrounding space. The Council of Trent defined transubstantiation as the traditional teaching of the Church chiefly in opposition to the view put forward by Luther, who, while he retained on Scriptural grounds the doctrine of the Real Presence and defended

* The doctrine of Transubstantiation had already more than once been the object of authoritative declaration on the part of the Church, namely, in a council held in Rome under Gregory VII, 1079 A.D.; in the Fourth Lateran Council (1215); in the profession of faith sent by the Council of Lyons to Michael Palæologus (1274); in the Decree for the Armenians which emanated from the Council of Florence (1445), etc.

it against the so-called "Sacramentarians," maintained, however, that the substance of the bread and wine remain after the consecration as before. This theory is called that of "Consubstantiation," a word implying the coexistence in the Sacrament of both the bread and the body of Christ. Another view advanced by some of the early Reformers who rejected the Catholic doctrine, is that of "Impanation," according to which in virtue of the consecration a hypostatical union would be effected between the person of Christ and the bread and wine.

But the specific controversy between the Roman Catholic theologians and the various Protestant sects concerning the *manner* of Christ's presence in the Sacrament has been practically lost sight of, because modern Protestants have for the most part given up the doctine of the Real Presence altogether, and interpret the words of institution (Matt. xxvi, 26–28, and parallel passages in the Synoptics) and other passages referring to the subject in a figurative sense. Many Catholic theologians maintain that even apart from the authoritative interpretation of the Church, the doctrine of Transubstantiation can be proved from the Scripture texts mentioned. In other words, that the idea conveyed by the word Transubstantiation is as clearly contained in the New Testament as the notion expressed by the words *ὁμοούσιος* and *θεοτόχος*, which were the keynotes of the Arian and Nestorian controversies. Others admit that a proof of the doctine, at least as it is philosophically explained, can be educed from the words of institution only by reading into them subtile considerations foreign to the minds of the Apostles and the New Testament writers. Be that as it may, we find that the early Fathers understand these texts as really implying the doctrine of transubstantiation. They do not, of course, use the word or attempt any philosophical explanation of the mystery, but they affirm that contrary to the testimony of our senses, what seems to be bread is no longer such after the words of consecration, but the body of Christ. Thus Saint Cyril of Jerusalem writes: "What seems bread is not bread, though it seems so to the taste, but Christ's body; what seems wine is not wine, though the taste will have it so, but Christ's blood" (Cathech. iv, 9). Similar passages abound in the patristic writings, and that they express equivalently transubstantiation few will deny.

In connection with this doctrine the Council of Trent has defined that in the Eucharist "the whole Christ (body, blood, soul and divinity) is contained under each species (that is, under the appearances of either the bread or the wine), and also under every part or portion of each species, at least after the parts have been separated" (Sess. 13, Can. 3). These two points offer no special difficulty if once the doctrine of Transubstantiation be admitted; it need only be remarked that they exhibit the intrinsic reason why the Catholic Church considers communion under one kind to be sufficient. If priests celebrating mass are obliged to receive under both kinds, it is only because their communion is held to be an integral part of the Eucharist sacrifice for which both species are absolutely required. For other more subtle questions connected with the theory of Transubstantiation as elaborated by the Roman Catholic theologians, together with the explanations whereby it was made to fit in with the philosophical systems of Descartes and Leibnitz, as well as with more recent theories, consult any of the standard manuals of Catholic theology, for example, that of Wilhelm and Scannell (in English), Vol. II, p. 415 et seq. For a criticism of the doctrine from the Protestant point of view, consult Hodge, 'Systematic Theology,' Vol. III, p. 678 et seq.

JAMES F. DRISCOLL, D.D.,
Rector of Saint Gabriel's Church, New Rochelle, N. Y.

TRANSVAAL, trans-väl (now included in the UNION OF SOUTH AFRICA), a British colony in South Africa, bounded on the north by Matabeleland, on the east by Portuguese East Africa and Swaziland, on the south by Natal and the Orange River Colony and on the west by Griqualand West, British Bechuanaland and the Bechuanaland protectorate. The area, previous to 1903, was 119,139 square miles but was in that year reduced to 110,426 square miles by the transfer of some of the southeastern districts to Natal. The land consists in the main of a plateau lying between 3,500 and 5,000 feet above the sea. On the east this plateau is bounded by a northern extension of the Drakenberg, rising to an altitude of 8,725 feet. East of this the land falls rapidly toward the coastal regions of the Portuguese territory. Two main mountain ranges traverse the interior of the plateau; the Witwatersrand forms the divide between the Vaal River, flowing on the southern, and the Limpopo River on the northern boundary. The geological structure consists of granite and slate covered by the Cape formation of standstone, slates and conglomerates, and in some parts by coal-bearing strata.

The climate is dry, nearly all of the scant rainfall being in the summer months, October to March. The mean maximum temperature is 73° and mean minimum 48°, mean annual 67° F. The western territory has a rainfall of 12 inches, which increases eastward, being 40 inches on the eastern border. Over 2,000,000 acres of land are under cultivation, and 30,000,000 acres are devoted to grazing. There are over 5,000,000 sheep and over 2,000,000 goats. The plateau and mountains are exceedingly rich in minerals, including gold, diamonds, coal, lead, silver, sulphur, cobalt, saltpetre, copper and iron. The gold deposits are foremost in the world. (See TRANSVAAL, GOLD MINING IN THE). In 1916 the production of diamonds, found chiefly near Pretoria, amounted to $28,000,000, and the coal to $6,000,000, copper $3,000,000 and tin $1,650,000. The diamond output in 1913 was valued at $57,000,000, but most of the mines shut down when the war of 1914 began. The climate in the eastern and northern lowlands is tropical; on the plateau it is cooler and very agreeable, but the rainfall is deficient. Forests, chiefly of acacias, are but of small extent. With irrigation the soil would be suitable for all European and sub-tropical agicultural products, but up to the present time there has been very little agriculture, the Boers being chiefly occupied in cattle raising. Railways have been built from Johannesburg to Delagoa Bay, Durban and the Cape ports. The mileage, about 2,500, is being

extended. The principal exports are gold, diamonds, copper, wool, cattle, hides, ostrich feathers, ivory and minerals. The chief imports are provisions, machinery, carriages, automobiles, shoes and clothing. The government is vested in an administrator, an executive committee of four and a provincial council of 36 members. Good schools are maintained; there were 892 in 1916, with an average attendance of 73,000. There are also three normal colleges and 298 native schools, with 20,000 pupils. The capital is Pretoria, and the largest city is Johannesburg (q.v.), with a population of about 120,000. The total population was given as about 1,688,212. Of these 1,219,845 were natives, Kaffirs, Basutos and Bechuanas. Only one-third of the white population were Boers (q.v.), the rest being, previous to the war, termed "Uitlanders." Transvaal was settled by Boers from Cape Colony in 1833–37. In 1856 they adopted a republican constitution, but internal disagreements, unwise administration and troubles with the natives forced the republic in 1877 to consent to annexation by Great Britain. In 1880, however, the Boers rose in arms, with the result that their independence was re-established, subject to British control over external affairs. The discovery of gold brought in large numbers of foreigners, chiefly English, who demanded a voice in the government. After fruitless appeals to Pretoria, and a disastrous attempt at insurrection in 1896 (known as the "Jameson Raid"), the Uitlanders appealed to the British government. After three years of negotiations England, in October 1899, rejected an ultimatum addressed to it by the Transvaal government, which thereupon invaded British territory. The war, in which the Orange Free State threw in its lot with the South African republic, lasted nearly three years. After a series of remarkable initial successes had been gained by the Boers, the two republics were finally occupied by British troops, and their annexation to the British dominions was proclaimed 1 Sept. 1900, although hostilities continued until June 1902. The War of 1914 stimulated manufacturing in the Transvaal, and they now tan their own leather, produce their own cement, beer and matches, besides manufacturing explosives, rope, brooms, brick and earthenware. See SOUTH AFRICAN WAR; TRANSVAAL, GOLD MINING IN THE; UNION OF SOUTH AFRICA.

TRANSVAAL, Gold Mining in the. The Transvaal, prior to 1903, comprised an area of nearly 120,000 square miles, but in that year, by the transfer of some of the southeastern districts to Natal, this area was reduced to about 112,000 square miles, which nearly equals the size of the territory of Arizona.

Besides the famous Witwatersrand there are two quartz-mining districts of some importance, namely, Lydenburg and De Kaap.

The Lydenburg district first attracted attention in 1876, when the alluvial deposits of that section began to be exploited. At a latter period vein-mining was started, and at the present time several companies are operating in that district. The product in 1898 of five companies, running 137 stamps, was 154,560 tons of ore, yielding 108,884 crude ounces of gold (an average of 14.09 dwt. gold per ton) valued at £314,953.

The De Kaap gold-fields were discovered in 1884. In 1898 seven companies, running 200 stamps, produced 89,760 crude ounces of gold, valued at £296,330.

General Features of the Witwatersrand.— This mining district derives its name from the *Witwatersrand*, or "white-waters range," of hills immediately north of Johannesburg. These hills rise from 400 to 600 feet above the general level of the surrounding country, have a general east and west trend, and constitute the watershed of this part of South Africa, their northern slope draining into the Limpopo River and thence into the Indian Ocean, and their southern slope into the Orange River and thence into the Atlantic. This ridge can be traced about 40 miles, and consists of quartzites and inter-stratified schists.

The gold-field lies on the high plateau of the southern Transvaal. In its physical aspect the country bears a striking resemblance to certain parts of Wyoming and Nevada. While perhaps somewhat less regular in its undulations, it is equally destitute of trees other than a sparse growth of shrubs, and in appearance suggests herding and agriculture rather than mining. It is from 4,200 to 6,000 feet above sea-level, to which fact it owes its temperate and mild, indeed salubrious climate, in spite of its semi-tropical latitude. The coastal lands contiguous to the Transvaal are malarial and unhealthful.

The soil of the country is in most localities fertile; but irrigation is generally necessary; and this, owing to the lack of facilities for storing water, is not feasible at the present time.

The Transvaal has a rainy season of four or five months, the heavy rains beginning usually with November or December and continuing until March or April. This is what is known as the summer or warm season. The thermometer rarely reaches 95° in the shade, and the heat is "dry." During the remaining "winter" months (April to September) rain is very exceptional, and there is no extreme cold. Snow is a rare occurrence in the Witwatersrand district. While the climate is remarkably salubrious and invigorating, the district has had in the past a high rate of mortality, by reason of the lack of proper sanitation. Undoubtedly this will be greatly minimized under better government.

The town of Johannesburg (q.v.) lies upon the southern slope, about midway between the east and west extremities of the "banket"-basin, immediately to the north of what is known as the central section of the Rand. This is by far the most important mining section of the gold-field. The Witwatersrand district, in a comprehensive sense, embraces also the outlying districts of Heidelberg and Klerksdorp. Johannesburg is reached by three railway lines from the ports of Cape Town, Delagoa Bay and Durban, the distance by rail being 1,013, 396 and 487 miles respectively.

Historical.— Mining in the Transvaal was prohibited until 1868, at which time the Boer government, being in dire financial straits, threw open the gold-fields to exploration and exploitation by all comers, and even went so

far as to offer a bonus for the discovery of profitable mines in the country. As a result, prospecting in the early '70s led to the discovery of quartz-veins and the inauguration of mining in several parts of the northern Transvaal. In 1885 the conglomerate- or "banket"-beds of the Witwatersrand were discovered. In that year a small stamp-battery was erected to crush the material of a quartz-vein a few miles west of Johannesburg and a crushing of conglomerate was subsequently made in this battery. But it was not until April 1887 that a battery of three stamps was erected to treat the ore of the Witwatersrand "banket." This was followed by the erection of other batteries and the output of gold for that year was 23,000 ounces. The product increased by leaps and bounds, as is shown by the table of production given later.

Mining Titles.—The mining laws of the Transvaal are excellent in character and while the claims cover every square foot of land for an area of nearly 40 miles long by from two to three miles wide there have been practically no conflicts over extra-lateral rights.

Notwithstanding the change in the political status of the Transvaal following the Boer War the main features of the mining law of the South African Republic are retained. The principles of the English common law and the immemorial precedents of English practice uphold present rights according to the statutes in force at the time of their inception. The mine-operators of the Transvaal whose titles were acquired from the Republic are, therefore, secure in the position thus defined; and hence it is not inappropriate in this place to state the Transvaal mining law as it existed prior to the war.

According to that law (1903) the right of mining for and disposing of all precious metals and precious stones belongs to the state; but the state president, with the advice and consent of the executive council, may, by proclamation, throw open government ground as a public diggings, upon which mining claims can be "pegged off" (that is, located) as specified by law.

An owner of a farm may, upon application to the government, have the farm likewise proclaimed. Before the proclamation of a private farm, the owner has the right of allotting to any person or persons he may specify a certain number of claims, called *Vergunning* claims, the number depending upon the size of the farm but not exceeding 60 as a maximum.

The owner has the further right to reserve for himself one-tenth of the ground, which is called a *Mynpacht*. This portion is held by the owner as a lessee, under what is called a *Mynpacht Brief*, for a term of not less than five years nor more than 20 years, with the privilege of renewal. The rental on *Mynpacht* was 10*s*. per *Morgen* (2.11 acres) in 1903.

He may also retain a certain area for residential and farming purposes, called a "*Wer*" or homestead. Finally, the owner of a proclaimed farm is entitled to one-half of all licenses paid to the government.

A reef-claim (lode-claim) is 150 Cape feet (155 English feet) on the strike of the reef by 400 Cape feet (413.2 English feet) in the direction of the dip — about 1.47 acres.

TABLE I — SOUTH AFRICAN LAND-MEASURES.

1 Cape ft.....	=	1.033 English ft.
1 Cape sq. ft....	=	1.067 English sq. ft.
1 Claim.....	=	150 by 400 Cape ft. = 60,000 Cape sq. ft. or 64,025 English sq. ft. = 1.47 English acres.
1 Morgen.....	=	92,196 English sq. ft. = 2.1165 English acres of 43,560 sq. ft.

Prospecting is not allowed on private ground without permission of the owner, but public ground is open to prospectors, though claims may not be pegged out until after proclamation of the ground in question as above described.

For a prospecting license on proclaimed private ground there is a charge (1903) of 5*s*. per month per claim, half of which goes to the owner and the rest to the government. On government ground the similar charge is 2*s*. 6*d*. per month, which goes to the government.

When, in the judgment of the mining commissioner, the results of the exploration justify the step, he may convert the prospecting licenses into a digger's license, after which a charge of 20*s*. per claim per month is made, provided ore from the property is being crushed. If, however, no ore is being extracted and crushed from the claim, the charge for the digger's license is 15*s*. per month.

In 1896 the receipts from prospecting licenses amounted to £620,000; from diggers' licenses, £61,000, and from machine-stand licenses, £59,000.

Financial Conditions.—At the outbreak of the South African War the total capitalization of the gold mines of the Witwatersrand was over £70,000,000 at par, and at market prices about £147,000,000. A large part of these amounts represents worthless properties which have been "floated" during "boom" times; yet, notwithstanding this excessive capitalization, the mines yielded about 7 per cent on the total capitalization at par, and about 3.5 per cent on market prices. Eliminating properties notoriously without value, and also the capitalization of certain "deep-level" properties which have not, as yet, reached a producing stage, we may pronounce the returns from bona-fide investment and competent management to have been exceedingly satisfactory.

In 1898 77 companies operating stamp-batteries produced 4,295,609 crude ounces of gold bullion of the value of £15,141,376, and of these companies 41 distributed in dividends for that year £4,847,505, or about 15.6 per cent on their nominal capital of £31,018,000. The market capitalization of the same companies, however, was £82,555,000; and the dividends returned on this capitalization were about 5.9 per cent.

The majority of the "outcrop companies"—indeed, nearly all of those situated in the central section (extending from the Langlaagte Estate to Knights, on the Witwatersrand) — are free of indebtedness and will not require further capital, unless for future increase of plant, especially for enlarging their milling capacity. Any additional capital required for such purposes could be provided either from the profits already earned, or by the issue of debentures, to be ultimately likewise redeemed from profits.

For the "deep-level" properties, on the other hand, and especially for those covering the deeper levels, that is, those situated on the second and third lines of claims parallel to the outcrop, a large amount of money must be ex-

pended before the mines can become productive. Instead of increasing the capital stock for this purpose it is generally the practice of the Rand companies to raise the money by the issue of debentures. There has been no difficulty in obtaining working capital by this means, often to the extent of £400,000 or £500,000. About £5,000,000 of such debentures were issued up to 1903.

Houses of high standing have been able to raise such loans of working capital upon debentures bearing interest at 5 to 6 per cent per annum, giving as an inducement to the purchaser the right to exchange the debentures for fully paid-up shares, at a certain price, within a given period from the date of issue, during which period the shares are likely to command a good premium.

Nearly all the Rand companies in 1903 were controlled by large financial concerns, such as Wernher, Beit and Company, who control the Rand Mines group and some other properties; the Consolidated Gold Fields Company, which controls the Simmer and Jack (one of the largest mines on the Rand), the Robinson Deep, the Nigel Deep and some of the first, as well as many of the second, row of "deep-levels"; the Messrs. Farrar, who control the East Rand Proprietary and its subsidiaries, the Angelo, Dreifontein, New Comet, etc.; Barnato Brothers, who control the Primrose, Glencairn, Ginsberg, Roodepoort, etc., and A. Goerz and Company, who control the Geldenhuis Estate, the May Consolidated, the Lancaster and the Geduld Princess Estate, etc.; Mr. Neumann and associates, controlling the Consolidated Main Reef, Treasury and Wolhuter; Messrs. Alba, controlling the Aurora West, Meyer and Charlton, George Goch, Van Ryn, etc., and J. B. Robinson, who controls the Robinson group, comprising the Langlaagte and Randfontein Estates and their several subsidiaries. These parties had the entire financial and technical direction of the companies in which they possess a major voting interest. All the important companies are listed on the stock exchanges of Johannesburg and London.

GOLD PRODUCTION OF THE TRANSVAAL.

1884–89	£2,678,231
1890	1,869,645
1891	2,924,305
1892	4,541,071
1893	5,480,498
1894	7,667,152
1895	8,569,555
1896	8,603,821
1897	11,653,725
1898	16,240,630
1899	15,728,693
1900	1,510,131
1901	1,096,051
1902	7,253,665
1903	12,589,137
1904	16,055,000
1905	20,802,000
1906	24,580,000
1907	27,404,000
1908	29,958,000
1909	30,926,000
1910	32,002,000
1911	34,992,000
1912	38,758,000
1913	37,658,000
1914	35,588,000
1915	37,264,000
1916	38,110,000

The financial administration of the Witwatersrand mines is, as a rule, able and honest. The Transvaal law requires a monthly statement of the amount of ore crushed, gold produced, etc. Such reports are published monthly by the companies in great detail.

As a rule, the Johannesburg local directors and mine managers are exceptionally trustworthy and full reliance can be had on the accuracy of their reports. Sometimes, however, attempts are made, for market purposes, to underestimate the working costs, by charging to capital expenditure money which should strictly be reckoned as working expenses. In this way fictitious profits may be shown; but the practice is not usual, and latterly has been seldom adopted.

In the formation of a new company the owner or owners of the mining claims (and often the financial promoting syndicates) usually receive a certain number of vendors' shares of the company to be formed by an amalgamation of claims. Moreover, a certain number of shares are sold (usually at par) for working capital; and a certain number of shares are retained as a treasury reserve, which frequently are sold, some time afterward, at a considerable advance. The majority of the companies have greatly increased their capital since their formation; but, notwithstanding this fact, their new shares are in many cases several hundred per cent above par.

Economic Conditions.— The methods of mining in the Witwatersrand district present no features specially different from those followed in the exploitation of similar deposits elsewhere. (See GOLD MINING; GOLD STANDARD AND GOLD PRODUCTION). In 1898 there were employed upon the Rand 9,476 whites and 88,627 Kaffirs. The attempt to introduce Chinese labor early in the century was but partially successful. In December 1915 there were 23,069 whites and 223,764 native negro workers in the mines. The white laborers are predominantly British, though the leading consulting and superintending engineers and many of the important members of the technical staffs are Americans. The mine- and mill-foremen are usually either Americans or British subjects who have had mining experience in America. These men are generally thoroughly competent; but the average of white labor as a whole, especially among carpenters and machinists, is far below the American standard. Considerable improvement, however, is taking place in this regard. A large part of the manual laborers on the surface and all the miners except those running machine-drills are blacks — Basuto, Zulu, Shangani and Zambesi "boys." The quality of this black (native) labor is very poor. Most of the "boys" are utterly inexperienced when first employed; and they rarely remain long enough to acquire great proficiency. When they arrive, making in many cases tramps of several hundred miles to reach the mines, they are in an emaciated condition and require to be "fattened up" for several weeks. After a few months' sojourn they become fine specimens physically; and, in some cases, they remain long enough at the mines to become expert miners. But it is exceptional to find great efficiency among the "boys" in drilling holes. They receive average monthly wages (1902) of £2 9*s*. and their board (which amounts to about 12*s* per month). Their task is a hole of three feet per day. The holes to be drilled are located by the shift boss

and the holes are fired by him, firing by the "boys" being usually forbidden. Some of them, however, acquire sufficient knowledge to fire a hole and also to run a machine-drill. The latter work is generally done by contract, and the contracts are given to whites.

By reason of the rapidly increasing demand for labor and the obstacles interposed by the Boer government, there was a great deficiency of native labor. As a result large numbers of air-drills have been necessarily employed in stoping, to the great disadvantage of the mines, since much of the ground is of such a character as to make stoping by machine-drills economically unadvisable. Where the reefs are flat or small, the employment of drills necessitates the breaking down of much larger blocks of ground than would be necessary with hand-drills. Moreover, work under such conditions involves the excessive use of dynamite — an important item where dynamite is as expensive as it has been upon the Rand — and creates at the same time an undue amount of fine waste, which not only lowers the yield of the ore in the battery, but increases the production of slimes.

The percentage of working costs of mining is given in the subjoined table, from which may be seen that the white and the native labor represent about 30 per cent each.

TABLE SHOWING PERCENTAGE OF WORKING-COSTS.

	Per cent
White labor	31.22
Native labor (including food)	29.83
Explosives (dynamite, fuse, caps)	9.70
Coal	9.07
Chemicals (cyanides, etc.)	3.22
Tools, steel, shoes, dies, etc	3.29
Mining timbers, lumber	4.05
Candles, lighting	1.38
Sundries	8.24
Total	100.00

Before the Boer War the difficulty of securing adequate labor was so pronounced that Cecil Rhodes, some 10 years ago, appealed to the Transvaal government for permission to import coolies for work in the Rand mines, but was met with a curt refusal on the part of President Kruger. Since the incorporation of the two Boer republics into the British empire matters have become still worse in this respect. For, whereas in 1897 about 100,000 Kaffirs were working in the mines, it was found impossible in 1903 to secure more than 60,000, and no fewer than 200,000 were needed. All attempts to obtain native labor from other parts of British Africa failed, owing to the inherent indolence of the black man and to his particular aversion to underground work. The consequence was that the owners were unable to work their mines to anything approaching their full limit. This was all the more serious when it is borne in mind that throughout the war, and for some time afterward, the Transvaal mines, comprising the most important gold-producing area of the world, were practically at a standstill, causing a scarcity of gold.

Conditions in 1917.— So far, we have been discussing conditions in the Transvaal in 1903, when the production was £12,589,000, or $60,000,000. Within two and a half years thereafter the Transvaal passed Australia in gold production and caught up with the United States. In 1906 the territory became, what it has ever since remained, the world's greatest producer of gold, with an output that year of $123,000,000. It could and should have been even greater, for the gold was there, and the stamp-mills, but the laborers were few. White men do not many of them care to go to South Africa, and the natives are not inclined to hard work. Chinese were imported, but they did not like it, and after getting in a few thousand the experiment was abandoned. Then came the tube mill, as an improvement on the time-honored steam-pump, and this helped the production. In 1903 the 7,915 stamps were half of them idle most of the time. In 1916 there were 9,250 stamps and 310 tube mills, and the product over three times as great, the average monthly reduction being 2,370 tons of ore, averaging 6.26 hundredweight gold per ton, or £3,170,000. The cost of production is still phenomenally low, although 54 per cent of it is labor. In 1916 the average ton of ore cost $4.34 to mine and turn into gold, and yielded a profit of $1.96. Those who think a gold mine must be all profit may well reflect on this, that if the cost in these greatest of mines had been 45 per cent greater, there would have been no profit in getting out the gold. The largest producing Rand mines in 1916 were the following:

	Monthly output of ore
Crown mines	203,000 tons
Randfontein Central	185,712 tons
East Rand Proprietary	155,500 tons
Knights Deep	102,400 tons

It is, therefore, apparent that the largest producer of these mines is yielding (at $4 a ton) over $8,000,000 a year of gold. Wonderful as this is, yet these four great mines are scarcely as valuable as some of the new mines coming into wealth in the Far East Rand territory. This new section has been developed by following the trend of the ore beds as they go deeper, and sinking shafts anywhere from 4,000 to 7,500 feet deep. These new mines are coming into their best, while those quoted are at their zenith or declining. T. A. Rickard considers the New Modderfontein the greatest mine in the world. In 1916 it was yielding 53,500 tons a month of very rich ore, averaging a value of $7.65 a ton, or 70 per cent more than the average for the whole Rand. But the wonderful part is that borings have tested out a continuance of this rich ore to the total of nearly 20,000,000 tons, so that this mine may reasonably look forward to a production of $125,000,000 worth of gold in the next 20 years. When will this phenomenal supply of gold give out, as all gold mines and gold fields do eventually? In 1903 the accepted estimate of remaining gold to be mined was $3,500,000,000. Since then $2,000,000,000 has been taken out, and yet some enthusiasts think there is $3,000,000,000 left.

South Africa as a whole gives no promise of becoming a leading factor in the economic life of the world. Mr. Bryce's forecast of the gold regions outside of the Rand throws light on the whole situation. He says:

"Assuming that a fair proportion of the quartz-reef gold fields turn out well, it may be predicted that population will increase in and around them during the next 10 years, and that for some 20 years more this population will maintain itself, though of course not necessarily in the same spots, because as the reefs first developed become exhausted, the miners will shift

to new places. After these 30 or possibly 40 years, that is to say, before the middle of the 20th century, the country, having parted with its gold, will have to fall back on its pasture and its arable land; but, having become settled and developed, it may count on retaining a reasonable measure of prosperity."

(The above was written by John Hays Hammond in 1903 and has since been revised by bringing the figures, etc., up to date.—ED.).

TRANSVAAL WAR. See SOUTH AFRICAN WAR.

TRANSYLVANIA, trăn-sĭl-vā'nĭ-ą (German *Siebenbürgen;* Hungarian, *Erdély*), Austria-Hungary; the southeast portion or region of the empire, since 1868 incorporated with Hungary; area, 21,500 square miles. The surface is mountainous, being covered with the Carpathian chain and its ramifications. The whole belongs to the basin of the Danube, which receives a great part of its waters circuitously by the Maros and the Szamos, both tributaries of the Theiss. The climate is healthful; the summer heat of the lower grounds is at times extreme. There are magnificent and valuable forests; fruits abound everywhere, and the culture of the vine is general. The crops include, besides the ordinary cereals, potatoes, etc., also maize, hemp, flax and tobacco. Fine breeds of horses, cattle and sheep are reared. Many horses are exported. Large numbers of swine are fattened. The wild animals include bears, wolves and wild boars. The minerals are important and include gold, silver, copper, lead, iron, quicksilver, antimony, coal and salt. The last occupies immense tracts. Manufactures have made little progress and are chiefly in the hands of Germans. The trade is chiefly confined to the natural produce of the country, and imported manufacturers. The chief towns are Kolozsvar (61,000), Brasso (41,000), Nagyszeben (34,000). Education is in a backward state. The population, about 2,500,000, is very mixed. Transylvania not being now a political division of Hungary, the reader is referred to Hungary for further statistics. The principal nationalities are Rumanians, Magyars and Germans, besides Gypsies, Jews, Bulgarians and others. The chief religious bodies are Roman Catholics, Greek Catholics and Protestants. The name Transylvania, signifying "beyond the woods," is due to the extensive forests on the western side. In ancient times Transylvania was a part of the province of Dacia. From the 4th century onward it was occupied by various nations in succession. In 1004 it was conquered by Stephen I of Hungary and was afterward governed by a viceroy (*voyvode*). In the 16th century the voyvode John Zapolya obtained Transylvania as a sovereign principality, but it could not maintain its independence against the house of Austria, and in 1713 was united to Hungary. In 1765 Maria Theresa raised it to the rank of a grand-principality. It suffered severely during the commotions of 1848–49, when there were massacres of the Magyars, and again in 1914–15 when it was invaded by the Russians.

TRANSYLVANIA COLLEGE, a nonsectarian institution of higher education at Lexington, Ky., founded in 1798. Its faculty numbers 29; the average annual attendance of students is 280; the tuition fees are $65; the living expenses, board, etc., $170. The productive funds amount to $414,936; the total income, including tuition or incidental expenses, to $43,253. The college colors are crimson. The library contains over 23,000 volumes. The number of graduates since organization is 3,555.

TRAP, any dark-colored volcanic rock of columnar structure, named with reference to their common stairlike arrangement. Most trap rocks are either finegrained basalts, diabases, diorites or gabbros. The term is a convenient one when the exact nature of the rock has not yet been determined and is largely used in field work. The Palisades of the Hudson, North Mountain in Nova Scotia, the Giants' Causeway and Fingal's Cave are familiar examples. The name is derived from the Swedish "trapp," applied to these rocks from their occurrence in step-like sheets.

TRAP-DOOR SPIDERS, large hairy theraphosid spiders of the family *Ctenizidæ* and its allies, which inhabit dry warm countries and form well-like pits or burrows in the ground, closed by a hinged lid. These burrows are placed in high, well-drained situations and are dug by the owners, who cut down and carry away the earth in their jaws, depositing it at some distance. The holes vary in size with the species and age of the occupant, and the largest may be more than a foot deep. The burrow of a species (*Ctenisa californica*) common in southern California is of that depth, and an inch in calibre, when the owner is fully grown. In some species the wells have a branch burrow slanting from one side, and others make two entrances, so that a plan of the burrow would resemble a Y. These burrows are lined with a coating of silk, and in every case the entrance (or entrances) is closed by a tight-fitting circular door composed of clay, bound and lined with silk, and hinged at one side to the lining of the burrow; the top of the door is left rough and earthy, so that when it is closed nothing betrays the presence of such a contrivance. In this snug castle the spider dwells in safety and comfort, rearing its young under the protection of the door, which it can hold so firmly shut that nothing short of tearing the structure apart will suffice to open it. In the species of the south of Europe the lining and door are much thinner than those made by the American trap-door spiders; and if these doors are torn off a new one will be made overnight, for several nights in succession or until the insect's strength is so exhausted that it can no longer produce the requisite silk. For further facts consult general works, especially Moggridge, 'Harvesting Ants and Trap-door Spiders' (London 1873). See SPIDERS.

TRAP-NETS. See POUND-NET FISHING.

TRAP-ROCK. See ROCKS; TRAP.

TRAP-SHOOTING, an outdoor sport increasingly and deservedly popular in the United States and Canada, in which by means of a mechanism now called the "trap" a disc of coarse pottery, "the clay pigeon," is thrown upward at an angle unknown to the sportsman, who thereupon sights his piece and fires while the disc is still in the air. The name trap-shooting is derived from the former practice of placing a series of traps in the ground, in each of which was imprisoned a live pigeon, and at a given signal of the marksman the operator

of the trap liberated one of the birds. The first mention of trap-shooting as a sport is found in an old English publication called the *Shooting Magazine,* issued in 1793, and it is there referred to as being a "well established recreation" of the period. Trap-shooting, both at live birds and inanimate targets, has become one of the most popular of British sports, but is not indulged in to nearly the same extent as in the United States. In the records of the Sportsmen's Club of Cincinnati, Ohio, for the year 1831 is found the earliest mention of trap-shooting in the United States. Cincinnati, therefore, appears to be the birthplace and early home of the sport in the United States. Passenger pigeons, and sometimes quail, were used in the sport. The Long Island Club was formed about 1840, and soon after the New York Sportsmen's Club was organized in that city. What may be termed the "glass ball" period in trap-shooting was inaugurated in 1866, when Charles Portlock of Boston, Mass., introduced the glass ball as the first substitute for live pigeons, and the new sport gained a considerable degree of popularity at once. In a few years improved traps for throwing the glass ball were developed and interest in the sport increased throughout the country. The first national trap-shooting tournament was held at New Orleans, La., 11–16 Feb. 1885, under the auspices of the National Gun Association. In the last quarter of the 19th century the sport became very popular; traps were improved, freaks in the shape of glass balls, which upon being hit belched forth smoke or feathers, were eliminated, and the now almost universal clay disc was introduced. The early rules for glass ball shooting were few: All matches or sweepstakes were shot over three traps placed 10 yards apart on a straight line. This was the same as the later rule made for target traps set Sergeant-system, except that the distance between the traps was less in the latter case. The traps were numbered 1, 2, 3, from left to right; No. 1 threw a left angle; No. 2 a straight-away, and No. 3 a right angle. The trap-puller was stationed six feet behind the shooter. The trap to be pulled was decided by the referee. He had three gun wads bearing the numbers corresponding to the traps and drew one from his pocket when the shooter took his place at the score, showing it to the puller who pulled the trap of that number. After the shooter took his place at the score he was not allowed to raise the butt of his gun above his elbow, under penalty of having the ball scored lost, whether it was broken or not. There was no restriction as to the size of shot used, or charge of powder, but not more than one and one-fourth ounce of shot was allowed. The rise was 18 yards, and all ties shot off at five single balls, 21 yards rise. In double shooting the distance was 16 yards, over two traps placed 10 yards apart; ties shot off at three pairs each, 18 yards rise. The same rules applied where the shooting was done over one trap, but the angle was changed at every shot, a screen preventing the shooter from viewing the angle of the trap. A late novelty in trap-shooting and one which greatly tests the skill of the marksman is the erection of the shooting towers. They are usually about 50 feet high and the "clay pigeons" are thrown from the top of the tower instead of from the ground. The levers are worked from below and hurl the targets at any desired angle.

The first and the only international trap-shooting contest was held at the Middlesex Club grounds near London, 11–13 June 1901. The conditions of the matches called for any 10 men from the United States against any 10 men from England, Ireland and Scotland, each man to shoot at 100 targets; the Americans to use but one barrel and one and one-fourth ounces of shot, while the British team were allowed the use of both barrels and one and one-eighth ounces of shot, the targets to be shot at 18 yards rise. A purse of $5,000 was to go to the winner of three out of five contests. The Americans won three consecutive matches, ending the contest on the third day, the total score standing:

	Americans	British
First Match	866	801
Second Match	877	794
Third Match	843	749

W. R. Crosby of the American team scored 93, 95 and 90 in the three matches as against 87, 87 and 83 by Izzard, Joynt and Pike, respectively, of the British team. On 19 June of the same year the American team defeated a picked Scottish team, the total score being American 969; Scottish 882. For a full and complete history of this sport, with illustrations of very many traps and discussions of their individual merits, together with rules for matches, scoring, etc., consult Eaton, D. H., 'Trapshooting' (Cincinnati, Ohio, 1918).

TRAPA. See SINGHARA NUT.

TRAPANI, trä'pä-nē, Italy, a seaport and episcopal see in Sicily, 47 miles west of Palermo, capital of a province of the same name in the extreme west end of the island. It is a walled town, and its port the safest on the western coast. The chief edifices are the cathedral, provincial palace and lyceum. A statue of Victor Emmanuel stands in the piazza bearing his name. The manufactures consist of coral, alabaster and shell objects, ice and olive-oil. There is an active trade in wine, salt and flour. The fisheries are important, especially sponges and tunny-fish. At a short distance northeast of the town is Mount San Giuliano, the ancient Eryx (q.v.). Pop. of the town about 15,000; of the commune 60,799; of the province, 367,507.

TRAPEZIUM, and TRAPEZOID, two geometrical terms. As commonly accepted in the United States the word trapezium is used to denote a quadrilateral of which no two sides are parallel, while trapezoid is the name applied to a quadrilateral two of whose sides are parallel. Ancient Greek writers did not always make a clear distinction in their usage of the two terms, and in England the definitions are the reverse of those here given.

TRAPHAGEN, Frank Weiss, American chemist and metellurgist: b. Eaton, Ohio, 20 July 1861. He was graduated from the School of Mines of Columbia University in 1882, and afterward pursued special studies in analytical and applied chemistry receiving the degree of doctor of philosophy. In 1884 he became an instructor in chemistry and physics at the military academy at Staunton, Va. He was professor of chemistry at the College of Montana,

1837–93, and in the latter year accepted the chair of chemistry at Montana State College, which position together with that of chemist of the Montana Experiment Station he occupied until 1903, when he was elected to the position of professor of metallurgy at the Colorado School of Mines, Golden, Col. In 1917 he became professor of metallurgy at the South Dakota School of Mines. He has published in addition to numerous State bulletins 'A New Departure in Cyanide Treatment'; 'Salicylic Acid in Fruits'; 'Notes on Alkali Soil in Montana'; 'Sugar Beets'; 'Food Adulteration'; 'Colorado School of Mines Notes,' on assaying and many articles on metallurgical subjects. Professor Traphagen is Fellow of the London Chemical Society, the Society of Chemical Industry, the German Chemical Society, the American Association for the Advancement of Science, the American Chemical Society, member of American Institute of Mining Engineers, and many other scientific bodies.

TRAPPISTS. See CISTERCIANS; ORDERS, RELIGIOUS; RANCÉ, DOMINIQUE ARMAND JEAN LE BOUTHILLIER DE.

TRASIMENO, Lago, lä'gō trä-sē-mā'nō. See PERUGIA.

TRASK, Spencer, American banker: b. Brooklyn, 1844; d. 31 Dec. 1909. He was educated in Princeton University from which he was graduated in 1866 to enter a Wall street banking house and in 1881 established one under his own name with branches in the larger cities. He was a supporter of many inventions including those of Edison; was identified with many corporations and was widely known as a man of philanthropic tendencies. He built Saint Christina's Home for Children at Saratoga and did much to restore the popularity of the springs there. He was killed in a railroad accident.

TRASKITES, the early designation of the Sabbatarian Puritans, an English sect. The title was derived from John Trask, of Somersetshire, who about 1617 became a preacher in London. Trask enjoined upon his followers a fast of three successive days, saying that with the third day's fast they would attain the state of justified saints; enforced the performance of all things according to the law of Scripture; required that Sunday be observed with a strictness equal to that with which the Jews observed the Sabbath; eventually made Saturday the day to be observed thus, this feature becoming distinctive of the sect; and established several ceremonial customs. In 1634 the commission for ecclesiastical causes included «Traskists» among the «separatists, novelists and sectaries» to be proceeded against by the authorities. Trask was haled before the Star chamber, and put in the pillory. Later, he is said to have recanted, though it is also recorded that before his death he became an Antinomian. The Traskites perhaps also assumed the title Separatists (q.v.). The modern Seventh-Day Baptists represent the Sabbatarian views of the Traskites.

TRASS, a trachytic tuff from the Eifel district, which is used on the Rhine for hydraulic cement.

TRAUTWINE, trowt'wīn, **John Cresson,** American civil engineer: b. Philadelphia, 20 March 1810; d. there, 14 Sept. 1883. He entered the office of William Strickland, a leading engineer and architect of Philadelphia, in 1828, and made rapid progress in the profession. He designed and had charge of the construction of the Penn Township Bank, assisted in the construction of the United States Mint and other public buildings, and in 1831 became civil engineer on the Columbia Railroad. He was engaged in railroad engineering until 1842, and in 1844–49 was associate engineer with G. M. Totten in the construction of the Canal del Dique, connecting Magdalena River with the Bay of Cartagena. In 1850 he was again engaged with Totten in making the surveys for the Panama Railroad. He was later occupied in a survey of the harbor of Arecibo, Porto Rico, and in railroad surveying in Pennsylvania. He went to Honduras in 1857 to survey the route for an interoceanic railroad, and in 1858 he examined the harbor of Montreal and planned for that city a system of docks. He retired from active business after 1864, though he continued to act as consulting engineer and expert. He published 'Method of Calculating the Cubic Contents of Excavations and Embankments' (1851); 'Field Practice of Laying Out Circular Curves for Railroads' (1851), and 'Civil Engineer's Pocket-Book.' This latter has become standard, is reissued at short intervals, and is popularly called 'Trautwine.'

TRAVANCORE, trăv-ạn-kōr', India, a native state in the province of Madras, occupying the extreme southwestern part of the Indian peninsula; area, 7,594 square miles. The soil is well watered, fertile and well cultivated. Coco and areca-nuts, pepper, tea and coffee are exported. The state is well administered, and both elementary and higher education provided for. It yields an annual revenue of about £761,000. The inhabitants are mostly Hindu, and ruled by a raja. Pop. about 3,428,975, being 452 to the square mile, which is excessively dense, even for India.

TRAVELER'S TREE, an arborescent plant (*Ravenala madagascariensis*) belonging to the family *Musaceæ*. It has a succulent or woody stem, and broad, shining, banana-like leaves, among the largest in the world. They are in two opposed rows and in one plane, and form a semi-circle above the base like an open fan, with ribs many feet long. The *Ravenala* is a very conspicuous object in Madagascar, its original habitat, and usually grows in clumps. Water from the surface of the leaves is conveyed down the channeled petiole to reservoirs in the excavated basal sheaths, whence the thirsty traveler can obtain a refreshing liquid even in the driest seasons. It is otherwise a very useful plant since the leaves are serviceable in house-building, as thatch, partition, and even in making walls. The hard, external cotex is stripped off, beaten flat and used for flooring. The green leaves do duty also as wrapping-paper, rain-sheds, table-cloths and dishes, and when folded properly, as spoons or drinking vessels. The large flowers are in a spathe, and are racemose, maturing into woody capsules, enclosing seeds that are edible and have a pulpy and lacerate blue aril yielding an essential oil.

TRAVELER, The. Oliver Goldsmith's 'The Traveler, or a Prospect of Society,' a

didactic poem in couplets, was published in 1764, with a dedication to the poet's brother, the Rev. Henry Goldsmith. The first of Goldsmith's works to attract wide attention, it went through many editions and was pronounced by Johnson the best English poem since the death of Pope. The theme is somewhat akin to that of Johnson's 'Rasselas.' From a point of vantage in the Alps the poet takes survey of the nations of Europe, asking which has the greatest share of happiness. He concludes that each government and way of life has its drawbacks as well as its advantages, and that the "bliss which centres in the mind" may be attained as well under one system as another.

> "Still to ourselves in every place consign'd
> Our own felicity we make or find."

The successive pictures of Italy, Switzerland and England are interesting and nicely differentiated. The versification is smooth and graceful and the expression felicitous. Especially pleasing is the intimate account of France, "gay sprightly land of mirth and social ease," where the poet himself in earlier days had piped to the "sportive choir." Goldsmith's mild political convictions appear in his rather unconvincing analysis of the ills of British freedom; his social sympathy, in the deprecation of luxury and selfishness on the part of the English landlords. Consult 'Poetical Works' (edited by A. Dobson, 1906); Macaulay, essay on Goldsmith, ('Miscellaneous Writings').

JAMES H. HANFORD.

TRAVELING LIBRARIES. A traveling library has been defined as "A collection of books lent for stated periods by a central library to a branch library, club, or other organization or, in some instances, to an individual." The chief characteristics from which it derives its name are its temporary location in the place to which it is sent and the implication that any traveling library will or may be changed for others.

The date of the first traveling library is uncertain. Passing by the itinerant chapman and ballad-seller, the religious colporteur and the camp library of Napoleon I listed in Bourrienne's 'Mémoires,' the "Circulating schools" of Wales, promoted in 1730 by Griffith Jones, and the later similar schools of the General Assembly of the Kirk of Scotland in the Highlands and the Scottish islands may be noted as forerunners of educational extension and its logical corollary, traveling libraries. The first really practicable traveling library plan seems to have been started by Samuel Brown in East Lothian, Scotland, in 1817, though it is stated that the principle had been used with some Scottish parish libraries as early as 1810. Brown procured 200 selected volumes "about two-thirds of which were of a moral and religious tendency, while the remainder comprised books of travel, agriculture, the mechanical arts and popular sciences." Four libraries of 50 volumes each were stationed in Aberlady, Salton, Tyninghame and Gawald. In 20 years these libraries had increased to 3,850 volumes, distributed through 47 villages. Jean Frédéric Oberlin is said to have founded itinerant libraries in his parish of Waldbach in the Vosges Mountains at about the same time that the East Lothian libraries were established. Both of these early plans barely survived their founders.

A successful system of traveling libraries was begun by the public library of Melbourne in 1860. Oxford University in 1878 and Cambridge University soon after began to send out traveling libraries as an aid to their university extension courses.

Traveling Libraries in America.— The American lyceum movement demonstrated the need of libraries to conserve the results of its work. "Itinerating libraries" and a county system of traveling libraries were proposed as early as 1831. In 1848, the American Seaman's Friend Society began to furnish libraries to American ships, afterward extending its work to naval hospitals and life-saving stations. The United States government has supplied similar libraries to lighthouses. These were exchanged frequently. The first general American traveling libraries supported by public funds were authorized by the New York State legislature in 1892. The first library was sent out by the New York State Library in February 1893. Beginning with 10 libraries of 100 volumes each the circulation for the first fiscal year was 2,400 volumes. This increased in 1918–19 to a total circulation of 43,958 volumes sent out in 1,099 different collections, with a total stock of 100,641 volumes. Michigan and Montana enacted traveling-library legislation in 1895 and Wisconsin and Iowa in 1896.

Virtually every State library commission now maintains a traveling library system for the libraries of its own State. The work of the traveling libraries section of the Educational Extension Division of the University of the State of New York may be taken as typical of the more highly organized form of this work in the State commissions. This division will send traveling libraries "to any place in New York State, preference being given to places where it is difficult to provide good books for free circulation." The State pays all transportation charges (other than local cartage). Seven different types of traveling libraries are provided: (1) Libraries for general readers; (2) libraries for public schools, to supplement the school libraries but not to provide supplementary readers or textbooks; (3) libraries for small public libraries, to supplement local library collections where library funds are scanty; (4) libraries for children; (5) libraries for foreigners, in several foreign languages; (6) libraries for study clubs, granges, private schools, Sunday schools, churches, etc.; (7) house libraries for the individual or the single family, preferably in rural homes.

When the books in these libraries are available to all members of a community no fee is charged for the first 25 volumes. In the case of restricted use (as in classes 6 and 7) a small fee is charged. Small fees are also charged for volumes in excess of 25. The period of loan is from three months (in the case of house libraries) to one year (in case of schools and study clubs). The collections are of two types: fixed and open shelf. The former are lent as a unit and the borrower is allowed no substitutions for titles on the list. The latter are selected from the general collection of the extension department to meet, as far as possible, the specific desires of the organization or person borrowing the library. The fixed collection is more economical as it ensures the use

of the whole collection; the open shelf collection is more flexible and, therefore, more satisfactory to most people. The tendency is toward the open shelf collection.

The large city libraries maintain similar systems. Their "deposit stations" are essentially traveling library collections. In addition, smaller collections of books are sent to clubs, schools, organized societies, police and fire stations and many other types of organizations. The New York Free Circulating Library, which had for several years supplied traveling libraries to schools, in 1897 established a traveling library department. This, which is now the Extension Division of the New York Public Library, in 1918 sent out 46,402 volumes to 417 agencies. The Free Library of Philadelphia began its traveling library work in 1896. A typical example of the use of traveling library books is seen in the Saint Louis Public Library which reports a circulation of 240,883 volumes in the fiscal year 1918–19.

An interesting variant of the traveling library is the book-wagon or automobile which delivers books along definite routes radiating from some library centre. The pioneer book-wagon in the United States was started in April 1905 by Miss Mary L. Titcomb of the Washington County Free Library of Hagerstown, Md. The Connecticut Public Library Committee and the Delaware State Library Commission have also maintained book-wagons. Book-wagons have also been used in parts of Wisconsin. A local book delivery automobile has recently been put into service by the Endicott (N. Y.) Free Library. To some extent rural mail delivery wagons have been used for traveling library purposes but the possibilities in this direction are capable of much greater development.

Several unsuccessful attempts have been made to establish traveling libraries on a commercial basis. The best known of these, the Booklover's Library and the Tabard Inn Library, founded in Philadelphia in 1900 and 1902 respectively, were measurably successful for some time.

Educational Significance of the Traveling Library.— The traveling library idea has spread throughout the civilized world and the small collection of books changed frequently is known in many places in which the more elaborate public library is as yet unknown. The late war was instrumental in giving the idea greater prominence than ever before. The case of books supplied by the Red Cross, the American Library Association or other relief organizations followed the troops into the trenches as well as into the camp and hospital and prison camps. It was a familiar sight on every war vessel or transport. The Germans as well as the Allies were quick to see the value of the traveling library in maintaining morale.

The great advantages of the traveling library are economy, mobility and adaptability. The collection is limited to books definitely chosen for some purpose. The obsolete and useless are eliminated. The frequent change of collections gives each group or community receiving the libraries access to the volumes in all the groups. Books on timely topics or those needed to meet changes in community taste can in this way be provided at a minimum cost. The traveling library can be put into the home, the store, the grange or wherever people congregate. It is not limited to any one place. No permanent building or special assistant is needed to make it give fairly satisfactory service if intelligence in selection is shown by the library which issues it. The only records needed are the simplest types of lending records.

The traveling library is of special significance in four different directions: in providing the rural population and special organizations with library facilities, in aiding the rural schools to keep their instruction abreast of the times, in promoting educational extension movements of all kinds and in promoting the establishment and development of permanent libraries. The town and village libraries, aided by the county library systems, are beginning to provide much more adequate library service for the rural population than formerly. (See RURAL LIBRARIES). Nevertheless, there will always be a considerable portion of the population for which the traveling library will furnish the only really convenient access to good books. Even the proposed extension of the parcel post service for library books at reduced rates will supplement, not supersede, the larger collection of the traveling library. The factory and the machine shop, the social club and the fraternal organization also find it much to their advantage to have immediately at hand a small, well-chosen collection of books changed often enough to prevent their becoming stale.

The rapid and extensive changes in school curricula and the modern methods of teaching, most of which imply considerable use of material outside the textbook, are making the school library more than ever an essential part of the well-equipped school. The rural and small town schools, no less than the schools in the large cities, need fresh books in their libraries. In most cases the funds available for this purpose are inadequate. The traveling library sent by the State Library Commission, the State Department of Education or other central agency, can fill this need better and at less expense than the local school board. It can supply the books needed to supplement the standard books, the reference books and the supplementary readers and textbooks which the school must have as a permanent part of its equipment. In many cases, the traveling library will show whether or not the desired book is really needed permanently. The value of the traveling library is so well recognized by teachers that practically no central distributing agency can supply the demand made by the schools for this service. In many cities (e.g., Rochester, N. Y., Buffalo, N. Y., Cleveland, Ohio, Portland, Ore., etc.), the public library has a regularly organized system of classroom libraries, changed at regular intervals and intended to supplement the school work. See also SCHOOL LIBRARIES.

Practically every well-devised scheme of educational extension, whether lyceum movement, university extension centre, study club, correspondence course, Chautauqua movement or Sunday school, has recognized the need of a small library to conserve and amplify the results of the instruction. The courses on a commercial basis have rather generally tried to sell personal collections to their patrons. Those without commercial intent have usually seen the need of larger, more flexible collections, available to all taking the extension work and sub-

ject to changes frequent enough to maintain variety. The traveling library has demonstrated its value in these cases. It has made it possible for the educational work to be varied in subject. It has enabled the ambitious student to go far beyond the limits of the lecture or the prescribed textbook. It has made true Carlyle's oft-quoted statement, "The true university of these days is a collection of books."

The development of traveling library systems has in most cases been followed by the establishment of permanent public libraries or the further development of those already established. The advantages of the traveling library are so manifest under such a variety of conditions that State legislatures have rather generally been willing to make some appropriations for their establishment and support. The traveling library implies a central administrative agency. This has required the formation of a State Library Commission or a similar body charged with the supervision of traveling library work. The traveling library, when intelligently used, has generally shown the need of larger, more stable collections of books than the library commission could supply. The logical result has been an agitation, by the study club, the school or the other organization using the traveling library, for a permanent public library. Many of the smaller libraries in all parts of the country have originated in this way. The "County system" has been the result as well as the cause of traveling libraries. The contribution of the American Library Association's war service libraries deserves special mention. Up to 1 Sept. 1919 the association had given 70 collections comprising 22,325 volumes to reconstruction units, colleges, universities and other permanent organizations in nearly 20 of the present countries of Europe and Asia. These collections are composed of books formerly used in the traveling libraries furnished the army, the navy and the marine corps through the American Library Association and other relief agencies.

Complete statistics of traveling libraries are rather difficult to obtain. As previously intimated, virtually every State Library Commission, every large public library, many extension departments of universities and an increasing number of commercial corporations maintain them. Different methods of calculating circulation and different interpretations of the term "traveling libraries" further complicate the matter. The more important original sources are indicated in the appended bibliography.

Bibliography.— Many references are included in Cannons, H. G. T., 'Bibliography of Library Economy' (London 1910), and in 'Library Work, Cumulated' (Minneapolis 1912). Current statistics of State systems are included in the 'League of Library Commissions Handbook' and in the bulletins of the various commissions. Statistics of city systems are to be found in the reports of the individual libraries. For the early history of the movement consult Brown, Samuel, 'Some Account of Itinerating Libraries and their Founder' (Edinburgh 1856); Brown, Wm., 'Memoir Relative to Itinerating Libraries' (Edinburgh 1836; reprinted New York 1836); University of the State of New York, 'Study clubs: annual report 1897' (Albany 1898; Extension Bulletin 23); 'Libraries and University Extension' (Albany 1892; Extension Bulletin 4); Dewey, Melvil, and Avery, Myrtilla, 'Traveling Libraries' (Albany 1901; Home Education Bulletin 40); and Adams, H. B., 'Public Libraries and Popular Education' (Albany 1900; Home Education Bulletin 31). On organization and management consult Hutchins, F. A., 'Traveling Libraries' (Boston 1902; American Library Association, Library Tract 3); Bullock, Edna D., 'Management of Traveling Libraries' (Boston 1907; American Library Association Library Handbook 3); Eastman, Linda A., 'Branch Libraries and other Distributing Agencies' (Chicago 1911; American Library Association Manual, chap. xv). Koch, T. W., 'Books in the War' (Boston 1919) describes the traveling library service of the different countries in the World War.

FRANK K. WALTER,
Vice-Director, New York State Library School.

TRAVELING SIDEWALK, a transportation system consisting of movable, parallel, continuous platforms to carry passengers from one point to another. They were first practically tested at the World's Columbian Exposition in Chicago in 1893 and since then successfully installed in Berlin. The sidewalk built for the Paris Exposition in 1900 was over three miles long and consisted of three parallel platforms, the outer one being stationary, the next having a speed of four kilometers and the inner one a speed of eight kilometers per hour. With these speeds it was found to be very easy to step from one to the other at any point. The system is excellent and practicable, and it is generally believed that only the opposition of existing traction interests prevents its adoption in a number of large cities. It has been proposed to build them for 3, 6, 9 and 12-mile speeds and to place seats on the speediest platform and run it under cover. It is estimated that they will carry more people at less cost in a congested territory than any other system.

TRAVELING STAIRWAY. See ESCALATOR.

TRAVERS, Jerome Dunstan, American golf champion: b. Montclair, N. J., 1887. He held the championship of New York for five years and of New Jersey for three years and won the national amateur title for six years in succession (1907–13), finally losing it to Ouimet in 1914. In 1915 he won the national open title. Author of 'Travers' Golf Book' (1913) and 'The Winning Shot' (1915).

TRAVERS, Morris William, English scientist: b. London, 1872. He was educated at University College, London, and in France. Returning to his home school he taught there until 1903; was professor in chemistry at Bristol and finally became director of the Indian Institute of Science at Bangalore (1906–14). He specialized in the study of gases at a low temperature and was the author of several books on the subject, notably 'The Attainment of Very Low Temperatures' (1904).

TRAVERSE CITY, Mich., city, county-seat of Grand Traverse County, on Grand Traverse Bay, an arm of Lake Michigan, on the Pere Marquette, the Grand Rapids and In-

diana, and the Manistee and Northeastern railroads, about 145 miles north of Grand Rapids and about 60 miles northeast of Manistee. Traverse City is in an agricultural and fruit-growing region. The excellent harbor gives the city shipping advantages to all the lake ports. The city is extensively engaged in manufacturing and is especially known for its production of oval wood dishes and corn starch. Other manufactures are flooring, fruit baskets, sash and doors, interior finishings, wagons and sleighs, farm implements, flour, leather, lumber and foundry and machine-shop products. The city has three banks with a combined capital of $310,000. The Northern Michigan Insane Asylum is located here. The city has a high school and five ward schools, municipal buildings, a public library and churches of all denominations. Traverse City was settled in 1852 and became a city in 1896. It is governed by a mayor and a council of 10 elected every two years. Pop. 14,000.

TRAVERTINE, calcareous sinter or chemically precipitated calcic carbonate, generally from streams or lakes, the waters of which contain an excessive amount of lime in solution. It either encrusts vegetable or inorganic matter, or forms a loose more or less porous or spongy mass on the surface of ledges. It is much used in Italy for building stone, Saint Peter's at Rome being constructed of it; the outer walls of the Colosseum also exhibit travertine. See SINTER.

TRAVIS, William Barrett, American soldier: b. Conecuh County, Ala., 1811; d. near San Antonio, Tex., 6 March, 1836. He was admitted to the bar in 1830, practised law at Claiborne, Ala., and in 1832 removed to Texas, where he soon after took up arms in the struggle for Texan independence. The old mission station of San Antonio de Valerio had been converted into a fort named the Alamo (q.v.) and Travis was in command of it with a garrison of 140 men, when, on 23 Feb. 1836, Santa Anna attacked him with a force of 4,000 Mexicans. The garrison defended the fort without the loss of a man for 10 days, though the only reinforcement which reached them was one of 32 men. A breach was finally made in the wall and in the desperate hand-to-hand struggle which ensued the entire force of Texans, with the exception of Travis and four of his men, were killed. The survivors were taken prisoners and were put to death by order of Santa Anna. The incident forms one of the most thrilling stories in American history, and the object of Travis, to engage the Mexicans for a sufficient period to enable General Houston to organize his army, was accomplished when six weeks later the Texans met and overwhelmed Santa Anna at San Jacinto, rallying with the war-cry "Remember the Alamo!" Consult Amelia Barr, 'Remember the Alamo.'

TRAWLING, a European mode of fishing, very common in some European waters, in which a net in the form of a large bag 70 to 100 feet long, narrowing to the closed end, is dragged along the bottom of the sea. The mouth or wide end of the net (in the "beam trawl") is kept open by a beam, at the ends of which are attached the ends of the rope by which the net is dragged along. In the "otter trawl," which has largely superseded the beam trawl, there is no beam and the mouth is kept open chiefly by two boards that rest edgewise on the bottom and are spread out diagonally by wire ropes attached to them and connected with the trawling vessel. In the narrow, closed end of the net the fish are collected and lest they should escape there is usually an inside net opening backward. This mode of fishing is practised to a very great extent in the seas round the British Islands, especially in the North Sea, for nearly all kinds of fish except herring and mackerel. Cod, whiting and other white-fish are taken in this way in large numbers and some kinds of flat-fish, as soles, can scarcely be taken in any other manner. There are many small steam-vessels engaged in this industry, which largely developed in recent years, but was largely crippled by the Great War. The method is often objected to as destroying fish spawn and ultimately tending to injure the productiveness of the fishing-grounds, but except, perhaps, as regards certain localities, this does not seem to be conclusively proved. However, it has been prohibited within three miles of the British shores and is not practised in the American fisheries.

TREACLE. See SUGAR GROWING AND SUGAR MAKING.

TREADMILL, originally a mill operated by man power, later adopted as a means of punishment, consisting of a large wheel, about 20 or 25 feet wide, with steps on its external surface, upon which the workers or criminals stand in the position of walking up-stairs. Their weight sets the wheel in motion and they maintain themselves in an upright posture by means of a horizontal bar fixed above them, on which they rest their hands, but they have to keep on climbing, climbing, until the weary task is ended. The power thus obtained may be applied to operate any convenient machinery. The treadmill is the invention of Sir William Cubit and was introduced into the prisons of Great Britain about 1820. It has been generally abolished.

TREADWELL, Aaron Lewis, American zoologist: b. Reading, Conn., 1866. He was educated at Wesleyan University and at the University of Chicago, at the last of which he took the Ph.D. degree in 1898. He became professor of zoology at the Miami University (1891–1900); was professor of biology at Vassar College (1900–14) and afterward was professor of zoology at the latter institution. He was instructor in marine biology at the government laboratory at Woods Hole, Mass. (1898–1906). He has written a number of articles on embryology and kindred topics.

TREADWELL, trĕd'wĕl, **Daniel,** American inventor: b. Ipswich, Mass., 1791; d. Cambridge, Mass., 27 Feb. 1872. His inventions include a machine for making wood screws, a power printing-press, a system of turnouts for single-track railroads and a machine for spinning hemp for cordage. As a consequence of this invention large works were erected in Boston in 1831 and several years later he furnished his machines to the Charlestown Navy Yard. He filled a contract with the government for 12 six-pounder cannon made of wrought iron and steel by an improved method

of his devising. This invention was secured by patent in the United States and England, and anticipated by at least 18 years the Armstrong gun formed upon the same plan with additional features. In 1822 he established and conducted, in connection with John Ware, the Boston *Journal of Philosophy and the Arts,* and during 1834–45 he was Rumford professor at Harvard. He published 'The Relations of Science to the Useful Arts' (1855); 'On the Construction of Hasped Cannon' (1864).

TREADWELL, Frederick Pearson, Swiss chemist: b. New Hampshire, 1857, but went abroad while still young and took the degree of Ph.D. at Heidelberg in 1878. In 1883 he went to Switzerland to become assistant in the technical school at Zürich where he became a professor in 1894. He is best known as the author of 'Handbook of Analytical Chemistry' (2 vols.), which has been translated into several languages and is used as a textbook in the United States.

TREASON. Treason is the highest crime known to society, and traitors by the law of every country are liable to the severest punishment. It is a crime directed against the very existence of the state itself and is, therefore, regarded as peculiarly odious. The ancient common law of England made a distinction between *petit* treason and *high* treason; thus it was petit treason for a wife to kill her husband or a servant his master; it was high treason for a subject to kill or attempt to kill the king or queen or to levy war against the king or adhere to his enemies. But this distinction was never introduced into American law. Here, what was known as petit treason was regarded as nothing more than murder. In England in early times judges sometimes declared offenses to be treasonable which were not so in fact. This was known as constructive treason. To remove this abuse Parliament enacted during the reign of Edward III the famous Statute of Treasons, which defined the offense of treason under seven heads, the third of which was levying war against the king and the fourth of which was adhering to his enemies and giving them aid and comfort. The framers of the Constitution of the United States preferring not to leave to Congress or the courts the power to define the offense incorporated in the text of the Constitution itself (Art. III, sec. 3) the definition of treason. This section declares that "Treason against the United States shall consist only in levying war against them, or in adhering to their enemies, giving them aid and comfort. No person shall be convicted of treason unless on the testimony of two witnesses to the same overt act, or on confession in open court." It will be seen that this definition embodies parts three and four of the Statute of Edward III but does not embrace the other parts of the statute. The word "only" in the definition, said Chief Justice Chase, was intended to exclude from the criminal jurisprudence of the new republic the odious doctrine of constructive treason. Under this definition only two classes of acts are treasonable: levying war against the United States and adhering to its enemies, giving them aid and comfort. The Supreme Court has interpreted the first part of the definition to mean that in order to constitute treason there must be an actual levying of war, that is, there must be a body of men actually assembled for the purpose of effecting by force a treasonable purpose. When this condition exists all those who perform any part, however minute or however remote from the scene of action, and who are actually leagued in the general conspiracy are to be considered as traitors. But if there is an actual assemblage for this purpose it is not necessary that actual violence should take place in order to make the assemblage treasonable. The Federal courts have even held that an insurrection of armed men, the object of which was to suppress the excise offices and to prevent by force and intimidation the execution of an act of Congress was levying war and as such was treason. It is more difficult to state the elements of the crime of "adhering to their enemies, giving them aid and comfort." Mr. Justice Field of the United States Supreme Court during the American Civil War charged a grand jury that "Whenever overt acts have been committed which, in their natural consequences, if successful, would encourage and advance the interests of the rebellion, in judgment of law aid and comfort are given."

In the recent case of Sir Roger Casement in England it was said in the indictment that "if a British subject commits an act which weakens or tends to weaken the power of the king and of the country to resist or to attack the enemies of the king and the country, that is in law the giving of aid to and comfort to the king's enemies."

Among the specific acts which have been held to come within the purview of the phrase quoted above are the selling of goods to and buying goods from the enemy government or its agents or forces; the communication of information to him with the purpose of aiding him; joining or offering to join his forces; delivering up of prisoners to him; trading with the enemy under certain circumstances; acts which tend and are designed to defeat, obstruct or weaken our own arms; advising, inciting and persuading others to give aid and comfort to the enemy, etc. Under the Constitution the testimony of at least two witnesses to the overt act is necessary to convict. An "overt" act is one which is of a character susceptible of clear proof and not one which rests on mere inference or conjecture. But an overt act may consist of words as well as deeds and while the testimony of two witnesses to the act is necessary to convict, it is not necessary to prove the intention. Nor is it necessary that the treasonable act should have been successfully performed. Thus the purchasing of a vessel, guns and ammunition for the purpose of using them in aid of a rebellion against the United States has been held to be a treasonable act.

Although treason is popularly regarded as a breach of allegiance it is now well settled that an alien as well as a citizen may commit treason, since if domiciled in the country he owes it a local and temporary allegiance in return for the protection which he receives. Although the Constitution defines treason it does not prescribe the punishment but confers that power on Congress, subject to the condition that no attainder of treason shall work corruption of blood or forfeiture except during the life of the person attainted. This limitation as to pun-

ishment was intended to prohibit the unjust early practice in England of cutting off the right heirs to inherit the property of a traitor. Under the provision of the Constitution the property of the traitor may be confiscated only during his lifetime; upon his death his property reverts to his lawful heirs. In 1790 Congress provided that any person convicted of treason should suffer death but the statutes as revised in 1909 provide that the court in its discretion may substitute imprisonment at hard labor for not less than five years and a fine of not less than $10,000.

JAMES W. GARNER,
Professor of Political Science, University of Illinois.

TREASURE ISLAND, Robert Louis Stevenson's earliest novel, is a vivid tale of pirates, adventure and buried treasure that brought the author his first taste of popular applause. Frankly designed for boys, its appeal to younger readers was as immediate as it has proved enduring; yet distinguished men sat up late to finish it; Andrew Lang spent over it "several hours of unmitigated bliss," and wrote, "This is the kind of stuff a fellow wants. I don't know, except Tom Sawyer and the Odyssey, that I ever liked any romance so well." The story was written and read a chapter at a time for the entertainment of Stevenson's stepson, Lloyd Osbourne, then a 12-year old schoolboy, to relieve the tedium of a rainy vacation, and grew out of a map that the author had drawn and labeled "Treasure Island." Stevenson himself says, "As I pored upon my map of Treasure Island, the future characters of the book began to appear there visibly among imaginary woods; and their brown faces and bright weapons peeped out upon me from unexpected quarters, as they passed to and fro, fighting and hunting treasure, on these few square inches of a flat projection." The story appeared serially, 1881–82, in *Young Folks,* as 'The Sea Cook,' taking that name from the more peaceful vocation of its splendid villain, "Long John Silver." The permanent title, 'Treasure Island,' was given to the tale on its publication as a book in December 1883. It has been widely translated and successfully dramatized.

ARTHUR GUITERMAN.

TREASURE TROVE, in English law, a name given any coin, gold or silver plate, or bullion found hidden in the earth or other private place. In Great Britain such treasure belongs to the Crown and any person finding it is bound to give information of the fact to the officers of the Crown. Failing to do so he is liable to fine or imprisonment. The Crown, on having treasure trove delivered up to it, is in the habit of paying to the finder its full value, in order that persons may not be induced to conceal such discoveries with a view to the profit, whereby many interesting remains of antiquity might be lost. The term is not often used in the United States and has not any technical legal meaning.

TREASURY, The Little ('Il Tesoretto'), an allegory in rhymed heptasyllabic couplets, was written probably in 1262 and not later than 1266 by the Italian scholar Brunetto Latini during his stay in France. This early mediæval poem, one of the oldest specimens of Italian didactic verse, antedates slightly the author's French encyclopedia 'Li Livres dou Trésor,' and can be considered an abridged Italian preliminary draft intended for a less cultured public. The immediate inspiration of the 'Tesoretto' was the first part of the famous contemporary French allegory, 'Le roman de la rose.' In his compilation which contains not quite 3,000 lines, Brunetto on his return from an embassy to Alfonso X of Castile learns that the Guelphs had been driven out of Florence (1260). Saddened by this news from his native town, he loses his way in a forest where he encounters Nature represented as a sovereign deity who undertakes his guidance and instruction. Then follows a typical medieval allegory with the usual personification of the various virtues, etc. Saved by Ovid from Pleasure (Love), Brunetto enters Montpellier, confesses to a friar, changes his mode of life, then continues his journey and reaches Mount Olympus where he engages in converse with Ptolemy. The poem breaks off just as the philosopher is about to reply in prose. Artistic value the work has not. Brunetto, learned and scholarly for his time, was no poet. The versification is of an inferior order. As Adolfo Bartoli well puts it, the couplets pass by like a procession of monks, all alike, without expression, without life. There is no characterization; the excess of detail, the minuteness of portrayal render the figures lifeless abstractions. The value of the poem lies, however, in the high moral tone that pervades the work, in the linguistic significance of this old example of Italian verse, in the code of knightly virtues so well set forth and above all in the influence over later writers, in particular, Dante. Consult Sundby, Thor, 'Della vita e delle opere di Brunetto Latini' (Italian edition, Florence 1884); Gaspary, Adolf, 'The History of Early Italian Literature' (English trans. by H. Oelsner, London 1901); Dole, Nathan H., 'A Teacher of Dante' (New York 1908). A critical edition of the 'Tesoretto' was published by B. Wiese in the *Zeitschrift für romanische Philologie* (Vol. VII, 1883).

ALFRED G. PANARONI.

TREASURY DEPARTMENT. The Treasury Department is that branch of the government service which has control of the national finances. It is under the direction of the Secretary of the Treasury, who is appointed by the President, with the consent of the Senate, and among cabinet officers, ranks second in the line of succession to the Presidency. His salary is $12,000 a year. He prepares plans for the improvement of the revenue and superintends its collection; directs the forms of keeping and rendering the public accounts and of making returns; grants warrants for all disbursements authorized by appropriations and submits to Congress, annually, estimates of the probable receipts and expenditures of the government for the ensuing year. The construction and care of public buildings and the administration of the coast guard and public health service are under his direction. He is chairman, ex-officio, of the Federal Reserve Board. Each of three assistant secretaries performs such a part of the duties of the secretary as he may prescribe.

The comptroller of the currency exercises

general supervision over the organization and regulation of national banks throughout the United States, including Alaska and Hawaii.

The treasurer receives and disburses all public moneys that may be deposited in the treasury at Washington, in the sub-treasuries and in the national bank depositories and makes authorized advances to disbursing officers.

The register signs all bonds of the United States and keeps records of the outstanding principal and interest of the bonded indebtedness of the government.

The designing, printing and finishing of all paper money, bonds and postage, customs and revenue stamps are done in the Bureau of Engraving and Printing, where also are prepared the pension certificates, commissions, disbursing officers' checks and portraits authorized by law, of deceased members of Congress.

The director of the mint has charge of all matters relating to the coinage. Tests of the weight and fineness of the pieces struck at the mints are made in his assay laboratory. The mints are located in Philadelphia, San Francisco, New Orleans, Carson and Denver.

The secret service is charged specifically by statute with the detection and arrest of counterfeiters and the guarding of the President of the United States.

The division of the Treasury Department which supervises the work of collecting the customs duties and of guarding against smuggling is a highly specialized organization. The country and its territorial possessions are divided into customs districts, in each of which places are designated where goods may be entered or delivered, according to law. Collectors of customs are required to execute and carry into effect all instructions of the Secretary of the Treasury in regard to the customs-revenue laws. In addition to the regular employees of this service, special agents are employed in foreign countries as well as in the United States, whose duties are along the lines of the detection and prevention of frauds against the revenues of the United States arising from customs.

The commissioner of internal revenue supervises the collection of internal revenue taxes and the enforcement of the laws related to them.

The comptroller of the treasury is really the chief of the auditing system of the Treasury Department and his decision is conclusive in the executive branch of the government. He is charged with the duty of revising accounts upon appeal from settlements made by auditors. Upon the application of disbursing officers or the head of any executive department, the comptroller is required to render his advance decision upon any question involving a payment to be made by them or under them, which decision, when rendered, governs the auditor and the comptroller in the settlement of the account involving the payment inquired about. He is required to approve, disapprove or modify all decisions by auditors making an original construction or modifying an existing construction of statutes and certify his action to the auditor whose duties are affected thereby. It is his duty to countersign all warrants authorized by law when signed by the Secretary of the Treasury.

The public health service conducts scientific investigations of contagious and infectious diseases and matters relating to the public health. The surgeon-general is required by law to call a conference of State and Territorial boards of health or quarantine authorities each year and additional conferences when, in his opinion, the interests of the public health demand such action. He has the care of sick and disabled seamen at 23 marine hospitals and 123 other relief stations. He enforces and regulates the national quarantine laws and has supervision over the medical officers detailed in the consular offices at foreign ports and those engaged in the mental and physical examination of arriving aliens.

The principal duties of the coast guard are rendering assistance to vessels in distress and saving life and property; destruction and removal of wrecks and other dangers to navigation; extending medical aid to sailors engaged in deep-sea fisheries; protection of the customs-revenue; operating as a part of the navy in time of war, when the President shall direct; enforcement of the laws relating to quarantine and neutrality; suppression of mutinies on merchant vessels; protection of game and the seal fisheries of Alaska and the enforcement of the sponge-fishing laws.

The supervising architect has charge of the erection of public buildings, selecting the sites, securing the necessary cession of jurisdiction from the States affected, preparing the drawings, estimates and specifications and superintending the construction thereof. He is charged with the care and maintenance of all Federal buildings outside of Washington.

While the Federal reserve board is actually an independent body, its work is closely allied to that of the Treasury Department and its headquarters are in the Treasury building in Washington. Its functions are to exercise supervision over the affairs of the Federal reserve banks, issue Federal reserve notes to member banks and in general to perform the various banking functions described in the Federal Reserve Act. The support of the board is derived from the several reserve banks, through assessments levied semi-annually, pro rata. It has full power to appoint its own employees and to regulate the conditions of their employment. Both the Secretary of the Treasury and the comptroller of the currency are members of the Federal Reserve Board.

TREAT, trēt, **Mary Lea Adelia Davis Allen**, American naturalist: b. Tompkins County, N. Y., September 1835. She was married to Joseph Treat in 1863, and has published 'Chapters on Ants' (1879); 'Home Studies in Nature' (1885); 'My Garden Pets' (1887); etc. She is also joint author of 'Through a Microscope.'

TREAT, Robert, American soldier and statesman: b. Pitminster, near Taunton, Somerset, England, 1622; d. Milford, Conn., 12 July 1710. He came to Massachusetts in 1635, removed to Wethersfield Conn., in 1637, settled at Milford in 1649, was assistant to the governor in 1657–65, represented Milford in the general assembly of New Haven colony in 1653–59, and from 1659 to 1664 was, with a year's exception, a member of the governor's council. Repeatedly elected magistrate of Milford, he was ordered at the Restoration to apprehend Whalley and Goffe, the regicides, who

were secreted there; but he appears to have postponed issuing a writ of search until they were beyond his jurisdiction. He was again made a deputy in 1663, but in 1666 went with a company of planters to found Newark, N. J. (q.v.), where he remained until about 1671, when he returned to Connecticut, becoming in 1673 a member of its council of war. In 1675, with the rank of major, he commanded the Connecticut force which defeated the Indian besiegers of Springfield and Hadley, Mass.; and in November of that year was appointed second in command to Governor Winslow in the New England forces in the field. (See COLONIAL WARS IN AMERICA, *King Philip's War*). For his services he was made deputy-governor of Connecticut in 1676. In 1683, upon the death of Governor Leete (q.v.) he became governor. In December 1686 Andros (q.v.) landed at Boston, with commission as royal governor of all New England, and he quickly set about attempting to abrogate the Connecticut charter. The general assembly met in October 1687, and Andros appeared with about 60 regular troops to enforce his demand. He did not get the charter; why, the records prudently omitted to explain. Tradition has an account (see CHARTER OAK), for the impeachment of which Johnston fails to discover good grounds. Treat yielded to superior force, and Andros' commission having been read, was made a member of the council for New England. After the deposition of Andros in 1689, Treat resumed his duties, and continued in office until 1698, when he refused re-election. For 10 years more, however, he was deputy-governor. Consult Johnston, 'Connecticut' ('American Commonwealths' series, 1887).

TREATIES. A treaty is an agreement or compact between two or more independent sovereign states for the settlement of their current interests or controversies, or for the purpose of increasing, modifying or determining their respective rights, duties and obligations, between themselves, or between each, and the subjects of the other. A treaty is somewhat similar to a contract in private law, an important difference being that its enforcement depends largely on the good faith of the contracting parties, and the fact that in case of a dispute the parties can settle it in only two ways; by agreement, or by an appeal to force. The term *treaty* includes various transactions between states, such as treaties of peace, conventions and agreements of a political or commercial character. The term is, however, usually restricted to the more important international agreements of a general character — to those covering several subjects such as a treaty of alliance, peace or commerce.

Treaties as a Source of International Law. — Treaties are an important source of international law, for a special agreement between two nations may work so well that other nations will enter into such an agreement, and the principle or practices involved may finally be accepted by all nations as a part of the common law of nations. Or a considerable number of important nations may declare for a new set of rules binding on themselves, which later may be adopted by others, as for example, the Declaration of Paris made in 1856, providing for new maritime rules referring to privateering, blockades, contraband, etc. Treaties entered into by a large number of powers, which redistribute territory, make or unmake dynasties and states, and set up a new balance of power, are also important sources of international law. Examples are the Treaty of Westphalia, 1648; Peace of Paris, 1763; Congress of Vienna, 1815, and the Peace of Versailles, 1919.

The Right to Make Treaties. — The right to make a treaty is one of the essential and determining attributes of sovereignty. Semi-sovereign or dependent states are easily recognized because of the fact that this right has been abridged or destroyed. Even sovereign and independent states may voluntarily restrain or modify this faculty by treaties of alliance or confederation with other states. Dependent states, restricted with respect to their right to make important international agreements, often retain power to make, unrestricted, certain treaties of a commercial character, or an extradition or naturalization treaty. Members of federal states are usually forbidden to make independent treaties, except those of a minor character. The States of the United States are forbidden by the Constitution to enter into treaty relations with foreign states or make agreements with each other except by the consent of Congress.

The treaty-making power, or the agent to whom the power is given to negotiate a treaty varies in individual countries. Ordinarily, in monarchical countries, it is vested in the Crown, but the approval of the legislative body may be necessary for ratification. In other words, power to negotiate and power to ratify are two separate steps. In states having a republican form of government the power to negotiate is usually exercised by the executive council. In the United States the treaty-making power is vested by the Constitution in the President, with the advice and consent of the Senate, two-thirds of the members present concurring. The preliminary negotiations leading up to the treaty and the drafting of the instrument, have in practice been in the hands of the President, usually acting through the Secretary of State, or through special envoys. The framers of the Constitution probably intended that the Senate should share in these preliminary negotiations, by giving advice as well as consent. The House of Representatives also may have a share in the treaty-making power, if legislation is necessary to carry it into effect, in which case its consent must be obtained.

The ambiguity with respect to the exact powers of the Senate in giving advice has never been settled. Washington personally appeared before the Senate on one occasion (1789) and asked its "advice" and consent respecting a proposed treaty with the Southern Indians. The Senate voted on seven specific questions respecting the proposed negotiations, favoring only a part of those proposed. Washington later, on several occasions, sought the advice of the Senate through special messages regarding proposed treaties, before negotiations were opened. President Jackson in a message of 6 May 1830 sought the advice of the Senate respecting the conclusion of a treaty with the Choctaw Indians in accordance with certain propositions therewith submitted. Presidents

Polk, Buchanan, Lincoln, Johnson and Grant sought the advice of the Senate respecting various treaties, conventions, etc. Nevertheless, the cases mentioned are exceptional. The Senate has on various occasions since 1883 advised the President by resolution concerning the negotiations of treaties by the executive, but such resolutions are not mandatory, and the right to adopt them is not dependent upon the treaty-making power. The President more commonly consults with individual members of the Senate, especially those on the Committee on Foreign Relations, to which all treaties are referred in the Senate.

The practice prior to 1815 was to submit to the Senate, for confirmation, the names of commissions designated to negotiate treaties, but since this date this course has been exceptional. Treaties have, with few exceptions, been negotiated through the Secretary of State, the regular diplomatic representatives and consular officers, or special agents, commissioned by the President, without special confirmation for this purpose by the Senate. A resolution was introduced into the Senate against this practice as early as 1833—that of appointing diplomatic agents to foreign countries by the President alone, without the advice and consent of the Senate. But on motion of Mr. Webster it was tabled. Again in a resolution of 9 Jan. 1883, consenting to a treaty with Korea, the Senate declared that it did not by that act admit or acquiesce in any right or constitutional power of the President to authorize any person to negotiate treaties with a foreign power, unless appointed and commissioned by and with the advice and consent of the Senate, except in the case of a Secretary of State or diplomatic officer appointed by the President to fill a vacancy during the recess of the Senate. The executive has, however, recognized no limitation in this respect, and special agents are employed including the famous case of President Wilson himself acting as one of the negotiators to the Peace of Versailles of 1919.

Respecting the question of giving consent, there has been no doubt and the Senate has rejected numerous treaties presented to it for ratification. Since the Senate has not usually been consulted with respect to the subject-matter of a treaty, it has exercised its co-ordinate power in treaty-making by means of amendments. The Senate by thus withholding action, may compel the President to enter into new negotiations again, in order to incorporate into the treaty its wishes. It may give its consent with an amendment. The President must then try and induce the other party to the treaty to accept the amendment. If such amendment proves unacceptable, then no treaty results. The President alone has the power to negotiate treaties, and he is the sole organ of the nation in its external relations, and its sole representative with foreign nations, except so far as he may delegate that power to some agent. Ratifications are exchanged only by virtue of special powers conferred on duly authorized agents, by the President, after the advice and consent of the Senate has been secured, two-thirds of the senators present concurring. The President may withhold from the Senate a treaty already negotiated. He may submit it to the Senate with a recommendation for an amendment, or a request that no amendment be made. The President may refuse to ratify a treaty even though the Senate has advised ratification. He may even withdraw a treaty from consideration by the Senate, in order to effect changes, or to terminate proceedings thereon. Certain agreements may be made by the President without the advice and consent of the Senate. While not technically treaties, such agreements are often their equivalent. It has been well stated that all treaties are agreements, but all international agreements and understandings are not "treaties." For example, President Monroe, through the acting Secretary of State, Mr. Rush, entered into an agreement 28–29 April 1817, with Great Britain, through the British minister, for the limitation of the naval forces to be maintained by the two governments on the Great Lakes. Nearly a year later the Senate declared, in answer to the request from President Monroe, that this was an arrangement the President was competent to enter into by powers vested in him by the Constitution, without the advice and consent of the Senate. Similar agreements have been made by our Presidents with sovereign nations, at various times, without the advice and consent of the Senate, respecting preliminary articles for peace treaties, reciprocal crossing of international boundary lines by troops of the respective countries in pursuit of bands of Indians, and for putting into execution treaty stipulations, etc.

The House of Representatives is not mentioned in the Constitution as one of the parties that must be consulted in making a treaty. But a treaty involving the payment of money, for example, can only be carried into effect by an act of Congress. Therefore, in such a case the consent of the House to a treaty must be secured before final ratification, if its execution is to be made certain.

How Treaties are Made.—The actual preparation of important treaties involving several states is usually the work of ministers, or representatives, selected for the special purpose, with definite powers to act on behalf of the government they represent. Rules of procedure are drawn up, the various representatives of the states interested are given an opportunity to submit projects or arguments affecting their interests, and the proceedings are put in writing and submitted to the various representatives for approval. The treaty is usually drawn up in the form of articles, stating who are the contracting parties, the purpose or object of the treaty, and the stipulations agreed on, such as boundaries, indemnities, terms of ratification.

Ratification.—Treaties must be ratified by the sovereign authority of the states which are parties to their operation in order to be binding. This act is completed through the exchange of written instruments identical in form and signed by persons given such powers by the supreme treaty-making power. Treaties may fail of ratification notwithstanding the fact that the minister or commissioners may have followed their instructions exactly. New conditions and the great magnitude of the interests of a nation make it necessary that the final consent shall rest in the nation itself after a review of the work of its agents.

Powers.— The nature and the extent of the treaty-making power includes the power to make peace, acquire and dispose of territory, recognize the independence of new states, change boundaries, guarantee territorial integrity of other states, provide for neutrality of countries, grant special privileges with respect to trade and commerce, and in fact consummate any other acts not inconsistent with sovereignty.

Validity.— The validity of a treaty depends upon several matters. Freedom of consent is indispensable to the validity of every agreement. But this does not mean that an engagement entered into by a nation under such duress as is implied by the defeat of its military forces, or the occupation of its territories, gives the conquered country the right to say that its consent was obtained by force. Nor does inequality in the conditions of a treaty form a sufficient reason for refusing to execute it. Treaties which violate fundamental principles of modern international policy are voidable; for example, acquiring of proprietary rights over the open sea, or a compact to re-establish the slave trade. The contracting parties must of course possess the full power to enter into treaty engagements, and the agents must not exceed the powers laid down in their instructions. The formal consent of the parties must be given. The subject matter of the treaty must be such that it is physically or morally possible of execution. For example, a clause involving a violation of the sovereign rights or power of a third state is invalid. Treaties properly entered into are binding, and are not affected by changes of government, and obligations involved may either release the other party or even be a just cause for war.

Kinds of Treaties.—Treaties are of various kinds and have been classified in different ways. There are special and general treaties. When a compact is put into effect and the object has been attained so that there is nothing further to be settled by future action, it is called an "executed" convention. Such compacts are binding on states regardless of changes of government. An example would be the settlement of a boundary question by treaty. All treaties which stipulate the performance of successive acts, executory treaties, to be continued through a period of time, limited or unlimited, fall into the second class.

Treaties of alliance, guarantee, commerce, arbitration, peace and the like, involving the performance of successive acts, are the chief means of regulating the intercourse of modern states. A treaty of alliance is an agreement of two or more states, for the purpose of securing their mutual desires. It may be offensive or defensive, or both; temporary or permanent, equal or unequal. Two states may guarantee the continuation of a certain state of affairs in a third state. Treaties of guarantee are entered into to secure the observance and execution of other treaties or the maintenance of certain existing conditions, such as the permanent neutrality of a state, for example,— Switzerland or Belgium, or the free navigation of a river or the neutrality of a ship canal. Treaties of commerce regulate the conditions of trade, and define the rights and duties of commercial intercourse, such as the exchange of raw materials and manufactured articles. Reciprocity treaties are compacts requiring mutual observance of certain duties or obligations. These involve such subjects as extradition, naturalization or copyright; for these are reciprocal on the subject named. Reciprocity treaties are, however, ordinarily thought of as commercial in character. They provide for the admission of certain products of each state into the ports of the other, at special rates, or duties, less perhaps than other countries pay, or without payment of any duty. Most treaties of arbitration are agreements between sovereign states to submit their disputes to tribunals or to a board of arbitrators, whose final awards they bind themselves to abide by. General arbitration treaties commenced to be entered into quite frequently from the middle of the 19th century, and have in recent years become very popular. The most important influence toward international arbitration of disputes was the calling of The Hague Peace Conferences of 1899 and 1907. The first provided for a number of conventions and declarations, one especially — the "Convention for the pacific settlement of international disputes" which was agreed to by the delegates of the 26 states represented, of which the United States was one. At the second conference 44 states were represented, and 13 conventions were agreed upon, the first of which dealt with the pacific settlement of international disputes, being a revision of that of 1899 with numerous additions.

Treaties of peace are similar in form to other treaties but the contracting parties do not enter into them on equal terms. They are nevertheless binding even though one of the parties has no real freedom of consent, and in fact may be compelled to sign a treaty under duress. Nearly every treaty of peace confers advantages on one side and imposes disadvantages on the other. In one sense the peace negotiation is a kind of extension, in another plane of conflict, of the military operations, in which the victor can threaten to resume hostilities, if his terms are not accepted. This kind of pressure is not exactly the same as duress. The defeated party may not consider that the use of such pressure gives him any right to violate his agreement; for he chooses to sue for peace and accept some hardships, in order to avoid the much greater evil of subjugation or annihilation. The victor might refuse to suspend hostilities until this event was consummated, with the result that there could be no treaty of peace. We may consider that the right of the victor to force the defeated party to accept his terms of peace is in the nature of a compensation for not pressing the victory to the extreme limit possible. Thus a treaty of peace is a compromise of necessity, unlike most other treaties which are equal transactions.

Objects Sought.— The constituent elements of treaties of peace vary considerably from other treaties because of the purposes and the condition of the belligerents. The fundamental object of a treaty of peace is first, to put an end to the war; secondly, to settle differences that produced it; thirdly, to settle whatever new differences may have arisen in the course of the hostilities. Two classes of articles may be distinguished, general and special. In the first class are those that relate directly to the cessation of the war and resumption of peace;

for example, provisions for the evacuation of territory, restoration of property captured, liberation of prisoners, the revival or abrogation of treaties concluded before the war. The special articles are those that relate to the essential points at issue — the terms on which peace is to be re-established, for example, the principal demands imposed by the victor on the vanquished, such as the cession of territory or the payment of indemnities, and the articles specifying the conditions and methods of carrying the main articles into effect. Miscellaneous articles deal with subjects peculiar to each individual treaty, such as provisions for demobilization, destruction of fortresses, rights of navigation or trade, establishment of new states, etc. Secret articles are sometimes agreed upon which do not appear in the treaty made public. Such articles may modify or suspend certain clauses of the open treaty, or even make new provisions, which are kept secret in order perhaps to avoid offending their states, or even to prevent opposition to the treaty by subjects of the parties who are signatories to the treaty. The date when the treaty is in full effect, especially treaties of peace, is not always easy to determine. The date when a treaty is signed does not necessarily show when the terms begin to operate. But the signing of the treaty marks the latest date for ceasing hostilities, unless otherwise provided for. The date when the treaty as a whole begins to operate, when peace is definitely and finally established, when the new status or position of the states begin, depends upon the date when ratifications have been completed and exchanged by all the parties signatory to the treaty, unless some other date is named in the treaty. The exact date of the operation of certain clauses may be indefinite or indeterminate, because of the operation of other clauses. For example, military occupation of the enemy's territory might continue for years, until the payment of an indemnity was completed.

Special Agreements.— There are a great variety of international agreements and acts involving matters of less importance than treaties that have been given special names. Those applied to the more special or limited subjects are protocols, notes, memoranda, declarations, conventions, congresses, cartels, etc. The word "protocol" is used in different ways, but commonly it means the preliminary document recording the fundamental principles or the particular points on which an agreement has been reached, thus serving as the basis for the final instrument. Notes are résumés of diplomatic conversations. Memoranda define in detail certain points on which misunderstanding might arise. Declarations are signed statements of principles which states intend to observe in their relations to one another. Conventions and congresses are bodies convened to discuss important questions of interest to several states, or for the purpose of settling questions of controversy. The conclusions may result in a treaty, or may be expressed in a statement of international policy, like the declaration of Paris, 1856. Examples of congresses on this continent are those of Panama, 1826, and those called by the United States known as Pan-American Congresses, which have convened at various times since 1889. Cartels are agreements entered into in time of war for the exchange of prisoners. They are the official acts of generals or admirals with the express or presumed consent of their governments. Capitulations are agreements entered into in time of war by commanders of armies or navies for the surrender of forts, armies, etc. Such action is subject to the approval of the government of the commander.

Interpretation of Treaties.— Treaties are subject to varying interpretations, because all possible cases that might arise cannot be foreseen. General terms applied to particular questions are the occasion for disputes concerning the meaning of the language used. European treaties are generally written in French. If England and the United States are parties they are drawn up in both languages, in parallel columns. The rules of interpretation include the following which are commonly recognized as valid. Interpretation must be mutual; only one true meaning can be given to a clause of a treaty; words are presumed to have been used in their usual sense; in case a treaty is in two languages, each document is regarded as original, and the sense of the treaty is to be drawn from them collectively; matters expressed in detail have precedence over those expressed in general terms; the treaty is to be regarded as a whole, its context and spirit, and each part with reference to others. The spirit of the treaty rather than the letter should govern in cases where literal interpretation fails to yield reasonable sense. Clauses favoring justice and humanity are to be construed more broadly than those involving cruelty or hard conditions. In general, the interpretation may be drawn from the connection and relation of the different parts; and with the purpose of keeping the treaty in operation, rather than of making it inoperative through disagreement as to details.

Treaties cease to be operative, or are terminated, under the following conditions: by mutual consent of the contracting parties; when terms upon which the treaty was conditioned cease to exist; when either party violates stipulations; when one party withdraws having the option to do so; when the performance of the treaty becomes impossible, as in the case of a triple alliance, with war breaking between two of the members, and the third state finds itself unable to fulfil its obligations; when a new state of affairs arises, overturning an existing state, the latter being the basis of the treaty; when the stipulations of the treaty limit the period of its operation. War may suspend the operation of a treaty, but not in all cases; for example, one entered into to amend the rules of international law, or one guaranteeing the neutrality of a state.

Renewal.— It is the usual, but not uniform practice, for the parties to agree in the treaty of peace to renew treaties existing between them at the outbreak of the war. Even without express stipulation as to renewal, it is generally agreed that certain treaty obligations are not annulled by war, but only suspended by it. For example acts previously done or rights already transferred under the sanction of a treaty are not nullified by a mere state of war; for example, a treaty in which territory has been ceded and boundaries established. Such

rights are, however, subject to the law of conquest.

Enforcement.— The enforcement of treaties is a subject of great importance, but also of great uncertainty. Unlike private contracts, where either party may compel the submission for a disputed interpretation to an independent tribunal for adjudication, treaties depend upon the good faith and honor of the contracting parties for their enforcement, and their willingness to agree. In case of disagreement either party determines for itself the nature of its obligations, and the only alternative is recourse to force, or denunciation of the treaty by the aggrieved party. Since the contracting parties are sovereign states no tribunal can exercise authority over them without their mutual consent. Various methods to insure the execution of treaties have been used, such as giving hostages, pledges, a guarantee by a third state, and military occupation of a territory belonging to the party who is required to fulfil certain demands within a stipulated time. The agencies for enforcement are the legislature, executive, army and navy and the courts. The first four are more important in the case of treaties of peace, commerce, etc., and the last in cases of naturalization and extradition.

Associate Professor of History, University of Chicago.

TREATIES, Indian. In a limited sense the Indian tribes of North America have always been treated by the government to which they were subject as foreign nations. Before the Revolution the king maintained diplomatic intercourse with those tribes residing within the limits of the territory claimed by Great Britain, and after the colonies became independent the relations between them and the Indians continued to be regulated through formal treaties, negotiated with their chiefs and approved by the tribe. The Articles of Confederation made provision for maintaining diplomatic intercourse with the Indian tribes by vesting in Congress the power to negotiate treaties with them. By the Federal Constitution the treaty-making power was vested in the President, and from the foundation of the government until a recent day the relations between the United States and the several Indian tribes occupying the territory embraced within the limits of the Union were regulated exclusively through regular diplomatic channels. These treaties were negotiated by commissioners or agents with the chiefs on terms of theoretical equality, and were ratified by the Senate according to the usual methods. Considering the actual dependent status of the Indians there was an element of absurdity in the practice of regulating the relations between them and the government to which they were subject, through diplomatic channels. Besides, this method proved inconvenient and at times embarrassing to the government. Finally by an act of Congress passed in 1871 it was declared that thereafter Indian affairs should be regulated directly by Congress and not by treaty. Since 1871, therefore, no treaties have been concluded with Indian tribes, but those existing at the time of the act were continued in force. The majority of the treaties between the United States and the various Indian tribes have been treaties of friendship or of cession, those of the latter class providing for the extinction of the "possessory right" of the Indians to the lands which they occupied and in some cases for the removal of the Indians to the territory especially set apart for their use west of the Mississippi River. Among the more important and best-known Indian treaties were those of Fort Stanwix of 1784 with the Iroquois, providing for the cession to the United States of western lands claimed by them; the Treaty of Greenville of 1795 with the Wyandots, Delawares, Shawnees, Ottawas, Chippewas, Pottawattomies, Miamis, Eel Rivers, Weas, Kickapoos, Piankeshaws and Kaskaskias by which a large part of the territory embraced in the present State of Ohio was ceded to the United States; the treaty of 1826 with the Creeks for the cession of lands in Alabama and Georgia; various treaties between 1791 and 1835 with the Cherokees for the cession of lands occupied by them in Georgia; the Treaty of Dancing Rabbit Creek of 1830 with the Choctaws for the cession of lands in Mississippi, and the Treaty of Pontotoc Creek of 1832 with the Chickasaws for the relinquishment of their claims to lands in the same State. Between 1828 and 1832 treaties were made with the so-called five civilized tribes, the Creeks, Cherokees, Choctaws, Seminoles and Chickasaws, as well as several other tribes of lesser importance, providing for their removal to the Indian territory west of the Mississippi. These treaties usually contained provisions for the payment of a lump sum to each tribe in consideration of the relinquishment of its lands, for the payment of annuities to the chiefs and the promise of various articles such as rifles, hoes, kettles, blankets and tobacco to each Indian who emigrated. Provision was also generally made for means of transportation to the Indian Territory and for supplying them with wagon-makers, wheelwrights, blacksmiths, millwrights, etc. Heads of families desiring to remain and become citizens were usually allowed to do so and were given 160 acres of land.

Down to 1837, at which time most of the Indians formerly residing east of the Mississippi River had emigrated to the Indian Territory,

the government had concluded 349 treaties with 54 Indian tribes distributed as follows:

With the Appalachicolas	2
With the Caddoes	1
With the Omahas	2
With the Cherokees	18
With the Chickasaws	8
With the Chippewas	21
With the Choctaws	11
With the Comanches	1
With the Creeks	12
With the Crows	1
With the Delawares	16
With the Eel Rivers	7
With the Floridas	1
With the Foxes	10
With the Hunkpapas	1
With the Illinois	1
With the Ioways	5
With the Kanzas	3
With the Kaskaskias	6
With the Kickapoos	11
With the Mahas	2
With the Mandans	1
With the Menomonees or Menominies	6
With the Miamis	10
With the Minnetarees, or Belantse-Etas	1
With the Missouris	4
With the Mohawks	1
With the Muscogees	2
With the Oneidas	1
With the Osages, Great and Little	7
With the Ottawas	19
With the Ottoes	5
With the Pawnees	6
With the Peorias	2
With the Piankeshaws	8
With the Poncarars	1
With the Poncars	1
With the Pottawattomis	38
With the Quapaws	4
With the Ricaras	1
With the Sacs	12
With the Seminoles	2
With the Senecas	12
With the Seven Nations of Canada	1
With the Shawnees	14
With the Siounes	1
With the Sioux	10
With the Six Nations of New York	4
With the Tetons	2
With the Weas	8
With the Winnebagoes	6
With the Wyandots	14
With the Yanctons	3

For the full text of these treaties with the date of the conclusion and ratification of each, together with the names of the commissioners and signatories consult 'Treaties Between the United States and the Several Indian Tribes from 1778 to 1837' (Washington 1837); consult also Weil, 'Legal Status of the Indian.'

JAMES W. GARNER,
Professor of Political Science, University of Illinois.

TREATIES OF THE UNITED STATES WITH FOREIGN NATIONS. The United States has always been a treaty-making country, as well as a treaty-keeping country. From the earliest days of its history as a nation, when as a new republic, flushed with victory and hopeful for the future, it appealed to the great foreign powers for recognition, the policy of almost every Congress has been to enter into such agreements, and there has been scarcely a Secretary of State who has not realized the necessity of devoting his energies to engendering such sentiments of mutual confidence and friendliness between the United States and other governments. Among the agreements thus established are the reciprocity treaties which have been a bone of contention among American statesmen for more than a century. Thomas Jefferson, while Secretary of State during Washington's first administration, urged upon Congress the adoption of such a reciprocity policy in regulating the customs and commerce of the United States with other nations:

> "As to the commerce," he said, "two methods occur: First, by friendly arrangements with the several nations with whom these restrictions exist, or, second, by the separate act of our own legislature for counteravailing their effect. There can be no doubt that, of the two, the friendly arrangement is the most eligible."

From Jefferson to McKinley, a period which represents practically the entire history of the United States, there have been few occasions when this sentiment has not been supported by some of the greatest men in the American political world, and the success of the reciprocity movement, so far as this country at least is concerned, undoubtedly inspired the last remarks of President McKinley. A few minutes before he was murdered he declared:

> Reciprocity treaties are in harmony with the spirit of the time. If some of our tariffs are no longer needed for revenue, or to encourage and protect our industries at home, why should they not be employed to extend and promote our markets abroad.

In 1909 the only countries with which the United States had no treaty were Abyssinia, Monaco and Montenegro; and those with which no treaties of peace, amity and commerce were established were Egypt, Rumania and Salvador. Among the most important treaties to which the United States has been a party are the various international agreements which have been executed at Geneva, at Brussels, and, since the establishment of the permanent International Court of Arbitration, at The Hague, and the fact that this country is fully in sympathy with the purpose of the court is shown by its anxiety to avoid armed conflict, and the readiness with which it has resorted to the more peaceful methods of arbitration offered by this international tribunal.

The table on following page is a list of the important international acts and conventions in which the United States has been an active participant.

Extradition Treaties.— In 1909 the United States possessed treaties of extradition with over 50 nations, the countries with whom no treaty existed being Bulgaria, China, Costa Rica, Egypt, Greece, Honduras, Korea, Morocco, Paraguay, Persia, Rumania and Siam. Such a treaty had existed earlier with Spain, but was expressly abrogated and annulled by Article XXIX of the Treaty of Friendship and General Relations of 3 July 1902. The crimes and offenses which are extraditable under the treaties in force in 1909 were generally interpreted as follows: Murder, homicide (comprehending assassination, parricide, poisoning, infanticide, manslaughter, when voluntary), or the attempts to commit any of these crimes; abduction, kidnapping or childstealing; bigamy, crimes against railroads, wrongful or wilful destruction or obstruction of railroads which endanger human life; arson; crimes committed at sea; piracy by the law of nations; revolt, or conspiracy to revolt, by two or more persons on board a ship on the high seas against the authorities of the ship; wrongfully sinking or destroying a ship at sea, or attempting to do so; assaults on board a ship at sea with intent to do serious bodily harm; rape,

SUBJECT	Concluded	Proclaimed by United States
Amelioration of the condition of the wounded in time of war	22 Aug. 1854	26 July 1882
Establishment of an International Bureau of Weights and Measures	20 May 1875	27 Sept. 1878
For international protection of industrial property	20 March 1883	11 June 1887
For international protection of industrial property (supplementary convention)	15 April 1891	22 June 1892
For the protection of submarine cables	14 March 1884	22 May 1885
For international exchange of official documents, scientific and literary productions	15 March 1886	15 Jan. 1889
General act for the repression of African slave trade	2 July 1890	2 April 1892
Formation of an international union for the publication of customs tariffs	5 July 1890	17 Dec. 1890
Regulating the importation of spirituous liquors into certain regions of Africa	8 June 1899	6 Feb. 1901
Relative to the pacific settlement of international disputes	29 July 1899	1 Nov. 1901
Relative to the laws and customs of war on land	29 July 1899	11 April 1902
Relative to the launching of projectiles and explosives from balloons, etc	29 July 1899	1 Nov. 1901
For the adaptation to maritime warfare of the principles of the Geneva convention	29 July 1899	1 Nov. 1901
Additional act for the protection of industrial property	14 Dec. 1900	25 Aug. 1902
Final protocol entered into at the conclusion of the Boxer troubles in China in 1900	7 Sept. 1901	.....
Conventions between the United States and other powers on literary and artistic copyrights	27 Jan. 1902	9 April 1908
Arbitration of pecuniary claims	30 Jan. 1902	24 March 1905
International sanitary convention (Paris)	3 Dec. 1903	18 May 1907
International sanitary convention (Central and South America)	14 Oct. 1905	1 March 1909
Repression of trade in white women	18 May 1904	15 June 1908
Exemption of hospital ships from payment of dues	21 Dec. 1904	21 May 1907
International Institute of Agriculture	7 June 1905	29 Jan. 1908
New agreement between China and certain powers for the Whangfu conservancy	27 Sept. 1905	.....
General act of the international conference at Algeciras	7 April 1906	22 Jan. 1907
International Red Cross convention for the amelioration of the condition of wounded of the armies in the field	6 July 1906	3 Aug. 1907
Importation of spirituous liquors into Africa	3 Nov. 1906	2 Dec. 1907
Unification of the pharmacopœial formulas for potent drugs	29 Nov. 1906	.....
International Office of Public Health	9 Dec. 1907	17 Nov. 1908
Second Hague Peace Conference conventions	18 Oct. 1907	28 Feb. 1910
Conventions concluded at the Central American Peace Conference	20 Dec. 1907	.....

offenses against chastity committed with violence; abortion, or procuring abortion; obtaining money or valuable goods under false pretenses (usually an amount in excess of $200); forgery, the utterance of forged papers; forgery or falsification of official acts of government, of public authorities or of courts of justice, of public or private instruments; the use or utterance of the thing forged or falsified; counterfeiting of government acts, seals, stamps, dies and marks of state, or public administration, or the fraudulent use of any of the above-mentioned objects; counterfeiting or altering money, whether coin or paper, the counterfeiting of titles or coupons of public debt, bank-notes or other instruments of public credit, and the utterance, circulation or fraudulent use of same; the introduction of instruments for the fabrication of counterfeit coin or bank-notes or other paper current as money; embezzlement of public moneys committed within the jurisdiction of either party by public officers or depositaries; embezzlement by any person or persons hired or salaried to the detriment of their employers; larceny (usually an amount not less than $200); burglary, defined to be the act of breaking and entering the house of another in the night time, with intent to commit a felony therein; robbery, defined to be the felonious and forcible taking from the person of another of goods or money by violence or by putting the person in fear; theft of horses, cattle or livestock (of the value at least $25); fraud or breach of trust by a bailee, banker, agent, factor, trustee or other person acting in a fiduciary capacity, or director or member or officer of any company, when such act is made criminal by the laws of both countries (usually not less than $200); obtaining by threat of injury or by false devices, money, valuables or other personal property (usually not less than $200); receiving moneys, valuables or other personal property with the knowledge that they have been stolen (usually not less than $200); perjury or subornation of perjury; crimes and offenses against the laws of both countries for the suppression of slavery and slave-trading; mayhem and any other wilful mutilation causing disability or death; bribery.

The United States has treaties, conventions and agreements on the following subjects with the countries mentioned: Peace, amity, commerce and navigation.—Algiers (peace and amity), Argentine Republic, Austria-Hungary (commercial), Belgium (commercial), Bolivia, Borneo, Brazil, Central America, Chile, China, Colombia, Congo (commercial), Corea, Costa Rica, Cuba, Denmark, Dominican Republic, Ecuador, Egypt (commercial), Ethiopia (commercial), France, German Empire (commercial), Great Britain, Greece (commercial), Guatemala, Hanover, Hanseatic Republics, Hawaiian Islands, Hayti, Honduras, Italy (commercial), Japan, Lew Chew, Liberia (commercial), Madagascar, Mecklenburg-Schwerin (commercial), Mexico, Morocco (peace, friendship and protection), Muscat, Netherlands, Nicaragua, Oldenburg (commercial), Orange Free State, Ottoman Empire (commercial), Paraguay, Persia, Peru-Bolivia, Peru, Portugal (commercial), Prussia, Russia (commercial), Salvador, Samoan Islands (commercial), Sardinia (commercial), Serbia (commercial), Siam, Spain, Sweden, Sweden and Norway, Switzerland, Tonga, Tripoli (peace and friendship), Tunis, Two Sicilies, Venezuela.

Trade-marks.—Austria-Hungary, Belgium, Brazil, Denmark (also industrial designs and models), France, German Empire (also patents), Great Britain, Guatemala (also patents), Italy, Japan (also patents and designs), Luxemburg, Netherlands, Rumania, Russia, Spain, Switzerland.

Copyright.—Austria-Hungary, Belgium,

Chile, Costa Rica, Denmark, France, German Empire, Great Britain, Italy, Japan, Mexico, Netherlands, Norway, Portugal, Spain, Switzerland.

Arbitration.—Austria-Hungary, China, Costa Rica, Denmark, Ecuador, France, Great Britain, Haiti, Italy, Japan, Mexico, Netherlands, Norway, Paraguay, Peru, Portugal, Salvador, Spain, Sweden, Switzerland.

Reciprocity.—Bulgaria, Cuba (commercial), Great Britain, Hawaijan Islands, Mexico.

Naturalization, immigration or emigration. —Baden, Bavaria, Belgium, Brazil, China, Denmark, Ecuador, Great Britain, Haiti, Hesse, Honduras, Mexico, North German Union, Peru, Portugal, Sweden and Norway, Uruguay, Wurttemberg.

The United States has other subjects on which treaties, conventions and agreement are based, besides the foregoing, among which may be mentioned the open door policy and exchange of notes and the final protocol at the conclusion of the Boxer troubles, with China; recognition of the flag, with Congo; interoceanic canal, with Costa Rica; agreement for lease of land for coaling station, with Cuba; readmeasurement of vessels, with Denmark; collection and application of the customs revenues with the Dominican Republic; alliance, act separate and secret, contract for payment of loans, cession of Louisiana and relations in Tunis, with France; general act concerning Samoa, with German Empire; tenure and disposition of property, with Guatemala; abolishing droit d'aubaine, with Hesse, Nassau, Saxony and Wurttemberg; reimbursing shipwreck expenses and exchange of notes declaring policy in the Far East, with Japan; pursuit of Indians (eight agreements) and claims ("The Pious Fund") with Mexico; interoceanic canal, with Nicaragua; right to hold real estate, with Ottoman Empire; neutrals at sea and whaling ships, with Peru; Pacific Ocean and northwest coast of America, neutral rights at sea, cession of Alaska, admeasurement of vessels, fur-seal fisheries and corporations, with Russia; regulation of the liquor traffic, with Sardinia; judicial procedure, discriminating duties, tonnage duties, commerce, with Cuba and Porto Rico, cession of outlying islands and letters rogatory, with Spain; property with Switzerland; neutrals at sea, with the Two Sicilies; and duties on liquors and consular powers, with Zanzibar.

The United States has made more treaties and other forms of agreement with Great Britain than with any other country. These include the following subjects: Naval forces on the Great Lakes; fisheries, boundary, and restitution of slaves; indemnity under the award of the emperor of Russia (1822); indemnity for slaves (1826); arbitration northeastern boundary; boundaries, suppression of slave trade, and extradition (Webster-Ashburton — 1842); boundary west of Rocky Mountains; ship canal connecting Atlantic and Pacific oceans (1850); cession of Horseshoe Reef; reciprocity, fisheries, and navigation; suppression of slave trade (1862, 1863, 1870); claims, fisheries, navigation, and boundary (Treaty of Washington, 1871); original modus vivendi concerning fisheries, 1891, 1906, 1907, 1908, 1909; general act concerning Samoan Islands; fur-seal fisheries; Bering Sea arbitration agreement; deserters from merchant vessels; Alaskan boundary, 1903-05-06; tenure and disposition of property; ship canal (Hay-Pauncefote Treaty, 1901); boundary line between United States and Canada, 1910, and boundary line in Passamaquoddy Bay, 1910.

The Second Hague Peace Conference Conventions (1907) contained the following provisions: Pacific settlement of international disputes; the limitation of the employment of force for the recovery of contract debts; opening of hostilities; the laws and customs of war on land; rights and duties of neutrals in land war; the laying of automatic submarine contact mines; bombardment by naval forces in time of war; the adaptation of the principles of the Geneva Convention to naval war; rights and duties of neutral powers in naval war; and a declaration prohibiting the throwing of projectiles and explosives from balloons. The International Prize Court, which meets at The Hague, when called together to settle some international dispute is composed of 15 judges, eight of whom are chosen by the larger marine countries, Germany, Austria-Hungary, France, Great Britain, Italy, Japan and the United States, the other judges being chosen from the remaining nations. In prize cases an appeal may be taken from national courts to the international court, according to the Convention of 21 Sept. 1910.

The conventions concluded at the Central American Peace Conference in 1907 contained provisions respecting peace and amity; the establishment of a Central American Court of Justice; extradition; the establishment of an international Central American bureau and a pedagogical institute; and regarding communications.

The following are the treaty negotiations of 1911: 24 February, new treaty with Japan was ratified by the United States; and on 4 April ratifications were exchanged at Tokio. The significant feature of this treaty is its omission of any explicit stipulation concerning the regulation of the emigration of the people of one country to the other. As part of this treaty, which is one of commerce and navigation, the representatives of the two countries agreed upon the proctocol of a provisional tariff arrangement and a declaration on the subject of immigration made by the Japanese government. Japan further agreed to continue to grant to the United States the "most favored nation" treatment in tariff matters, pending the negotiation of a special agreement.

On 17 May 1911 the draft of a general treaty of arbitration was submitted by Secretary Knox to the British and French Ambassadors; and on 28 June it was announced at Washington that this treaty had been agreed upon in every important provision. It is the first comprehensive agreement for arbitrating practically all disputes that can arise between two sovereign nations, including even questions of vital interest and national honor. It provides for arbitration by The Hague court of all questions, without reservation, that are regarded by the contracting parties as proper for arbitration. All other disputes are to be submitted to a commission of inquiry, to be composed of the permanent court of The

Hague. This commission will investigate and report whether or not the matters in controversy should be arbitrated. This treaty was signed 3 Aug. 1911 between the United States, Great Britain and France and was finally ratified 7 March 1912.

On 28 June a treaty abolishing pelagic sealing was signed at Washington by representatives of the United States, Great Britain, Russia and Japan.

On 26 January the reciprocity agreement between the United States and Canada was submitted to the legislative bodies of both countries. It was upheld in Congress, but in the Canadian elections on 22 September the party supporting the proposed trade reciprocity was defeated.

The most important event in which the treaty-making power of the United States was involved at the end of 1911 was President Taft's abrogation of the Russian Treaty of 1832 with this country. This was done 17 December by his directing the American Ambassador at Saint Petersburg to denounce the treaty in friendly terms. The notification that he had so acted was delivered to the Foreign Office 18 December. The action was taken by the President on the primary ground that Russia had violated the terms of the treaty by refusing to visé passports for American citizens of Jewish birth or Catholic faith. The House had voted 300 to 1 demanding abrogation. The operation of the treaty — which was one of commerce and navigation — ceased by this action on 1 Jan. 1913.

Under an agreement entered into between the United States and Great Britain 20 July 1912 all outstanding claims between the two countries shall be submitted to arbitration. The arbitration treaty with France which expired in 1913 was renewed in February of the same year. In 1914 the so-called Bryan-Wilson treaties were presented by the United States to various foreign countries. The object of these treaties was to provide a means of preventing international trouble from developing into war. In general these treaties stipulate that the contracting parties to the treaty shall, in each case, submit to a commission all international disputes that cannot be settled by diplomacy. The contracting parties to each treaty bind themselves not to declare war or begin hostilities until such time as the commission shall have submitted its findings. Each nation is free to disregard the report of the commission if it should see fit to do so. The following countries entered into the Bryan-Wilson treaty agreement with the United States: Salvador, Guatemala, Panama, Honduras, Nicaragua and The Netherlands in 1913; Bolivia, Persia, Portugal, Costa Rica, Switzerland, Dominican Republic, Venezuela, Denmark, Italy, Norway, Peru, Uruguay, Argentina, Brazil, Chile, Paraguay, China, France, Great Britain, Spain, Russia, Ecuador, Greece, Sweden, in 1914; and Norway in 1915. For the Peace Treaty of the World War, signed 28 June 1919, see WAR, EUROPEAN — TREATY OF VERSAILLES. See also INTERNATIONAL CLAIMS AND DISPUTES; HAGUE COURT, THE; INTERNATIONAL LAW.

TREATING. See CORRUPT PRACTICES ACTS.

TREATY, an agreement, league or contract between two or more nations formally signed by commissioners properly authorized, and ratified by the supreme power of each state. Treaties are not admissible by subordinate States, for instance, New York State cannot make any binding treaty with Canada, as that is the province of the Federal government at Washington. The conditions that govern or should govern treaties are defined in INTERNATIONAL LAW (q.v.). The treaty-making power of the United States is vested in the President, though the work of treaty-making falls to the office of the Secretary of State. It is usual for the President to seek the advice of the Senate in making a treaty, in order that it may receive their prompt ratification. The Senate has the right to return a treaty for amendment or reject it. When the Senate ratifies, the President, through the Secretary of State, may sign and conclude the treaty. A treaty so made overrides all State laws, even their constitutions, but it cannot deprive individuals of their constitutional rights. Where a treaty involves a payment of money the House of Representatives, where all appropriation bills must originate, has claimed a right to participate; but this claim remains disputed. In France the President makes treaties. In countries where there is a sovereign it is usually his privilege, though he may be held in check by legislative power. Treaties of alliance are common, as the well-known alliance between Great Britain and Japan made in 1902 and extended in 1905, which resulted in bringing Japan into the World War. Treaties regarding boundaries and distribution of territory are also common; submission of differences to arbitration; trade agreements; navigation and fishing regulations; exchange of moneys, mail, etc.; protection of copyrights; return of criminals; adoption of rules of international law; adoption of recommendations of The Hague Peace Tribunal.

Some famous treaties are Westphalia Treaty, closing the Thirty Years' War, in 1648, in which most of the nations of Continental Europe participated; Peace of Utrecht, a series of treaties between 1713 and 1715, between France, as opposed to England, Holland, Prussia, Savoy and Portugal; treaty of independence of the United States, accepted by Great Britain at Paris in 1783; the parti-

tion of Poland in 1772 and again in 1793; the separation of Belgium and The Netherlands, made at London 1831 and modified 1839; cession of part of Lombardy to Sardinia in 1859; dissolving the German Confederation and establishing of the North German Confederation with full recognition by Austria, the transfer of Schleswig-Holstein to the new confederation and ceding the balance of Lombardy to Italy in 1866; Treaty of Frankfort, being new treaty of France and the German Empire after the War of 1871; settlement of territory growing out of Spanish-American War, between United States and Spain, 1899; Russo-Japanese treaty of peace at Portsmouth, United States of America, 1905; the German Peace treaty signed at Versailles, 1919. Various agreements tending to mitigate the horrors of war have been incorporated in treaties on numerous occasions. Guarantees for the performance of conditions in treaties are usually demanded and formerly it was customary to give hostages. International law has been framed as the recorded customs governing civilized nations in carrying out their treaties. Refusal to abide by a treaty is a cause of war, since treaties bind both parties until mutually abrogated. It is generally conceded that a war wipes out all previous treaties between the parties and that they have to be made again to come into force. If a state change its government, as in going from a monarchy to a republic, all treaties are void and have to be remade with the new government to be effective. Consult 'Treaties, Conventions, Etc., Between the United States of America and Other Powers, 1776–1909' (Washington 1910); Herslet's 'British and Foreign State Papers' (London); Albin, P., 'Les Grandes Traités Politiques' (Paris 1911); Crandall, S. B., 'Treaties: Their Making and Enforcement' (Washington 1915). See HAGUE COURT, THE; TRIPLE ALLIANCE; TREATIES; TREATIES OF THE UNITED STATES WITH FOREIGN NATIONS; WAR, EUROPEAN — TREATY OF VERSAILLES.

TREATY, Anglo-Japanese. See ANGLO-JAPANESE TREATIES.

TREATY ELM, a celebrated tree, formerly in the environs of Philadelphia, Pa., under which William Penn (q.v.) negotiated a treaty with the Indians. A monument marks its place.

TREATY PORT, a port open to commerce with certain nations in accordance with the terms of a treaty, in a country not generally open to foreign commerce. China is the one nation where treaty ports were for many years of importance; the first ports were opened to trade by the Nankin treaty with Great Britain in 1842; these ports were Canton, Amoy, Fu-Chau, Ningpo and Shanghai. Since then other treaty ports have been established, by the treaty with Japan in 1895 and by the treaty with the powers in 1902. About 1900 they numbered over 30, and include Samshui, Wuchow, Whuhu, Shasi, Chung-King, Yochow Hangchow, Su-Chau, Lungchow, Niu-Chwang (the most northern), Chang-Sha, Ngan-King, Wan-Hsien, Wai-Chau and Kong-Mun. Since 1912 the Republic of China has made all her ports free. Japan was also first opened to foreign commerce by means of treaty ports; the first treaty in March 1854 with the United States opened two ports, Simoda and Hakodadi, to American commerce; in the same year the British gained access to two ports, and later the Dutch and the Russians; by subsequent treaties both the United States and Great Britain gained more ports and further privileges. In 1899 Japan was recognized as on an equality with the other powers, and the whole country thrown open to foreign trade.

TREATY OF PORTSMOUTH. See PORTSMOUTH, TREATY OF.

TREATY OF SAN STEFANO. See SAN STEPHANO, TREATY OF.

TREBBIA, trĕb'bē-ä, Italy, a tributary of the Po which rises in the mountains of Liguria. It was on the banks of the Trebbia that the Romans under Sempronius were defeated, 218 B.C., by the Carthaginians under Hannibal.

TREBIZOND, trĕb'ĭ-zŏnd, Asia Minor, (1) A seaport, military station and capital of a vilayet of the same name, in the northwestern extremity, on the Muchka where it enters the Black Sea, 120 miles northwest of Erzerum. It has a citadel, mosques and churches; its streets are irregular and narrow. It is the see of an Armenian archbishop, a United Armenian bishop and a Greek metropolitan. Its trade is important. The exports consist of tobacco, carpets, silks, fabrics, cattle, raisins, walnuts and hazelnuts. The imports are cotton and woolen manufactures, sugar and silks. It was founded by the Greeks about 700 B.C. On the establishment of the empire of Trebizond by Prince Alexius, in 1204, this city was made the capital. The Turks overran the region and took the city in 1641. It was captured by Russia in 1916, but owing to the disruption of the Russian forces it was not long held. Among the Greek major and minor claims at the Peace Conference in Paris 1919 was the proposal to form the Pontian Republic of the region around Trebizond, with the ancient city as the capital. Trebizond is the residence of foreign consuls. Pop. 55,000. (2) The vilayet or province has an area of 16,671 square miles. It has great mineral riches and extensive forests, and a mixed population. Pop. 1,265,000.

TREBLE, Lillian Massey, Canadian philanthropist: b. at New Castle, Ontario, 2 March 1854; d. California, 1909. She became interested in mission work and organized classes in domestic science which led to her founding The Lillian Massey School of Household Science and Art. Similar results were secured at Toronto and other universities and she gave the Toronto University a handsome building which was opened in 1913.

TREBUCHET. See ORDNANCE.

TREE, Sir Herbert Beerbohm, English actor: b. London, 17 Dec. 1853; d. 2 July 1917. He was a son of Julius Beerbohm, and was educated in England and Germany. After entering upon a business career he became interested in private theatricals, and adopted the profession of the stage in 1878. Succeeding in this, he assumed the management of the Haymarket Theatre in 1887, and became one of the most conspicuous of the actor-managers of recent times. After 1897 he played in his own theatre, Her Majesty's, one of the best constructed of

London playhouses. He possessed great versatility, and played parts ranging from Hamlet to Falstaff. Tree achieved an early success in 'The Private Secretary' (1884). This was followed by Macari in 'Called Back,' and by the part of the Russian Spy in 'The Red Lamp' (1887). In eccentric character parts he essayed the leading rôles in 'The Ballad-Monger' and in 'Trilby.' In modern social drama he appeared in 'A Bunch of Violets,' 'Captain Swift,' 'A Woman of No Importance,' 'John-a-Dreams,' 'The Dancing Girl' and 'The Tempter'; while of Shakespearean plays he produced 'Merry Wives of Windsor,' 'Hamlet,' 'Henry IV' and 'The Taming of the Shrew.' Stephen Phillips' 'Herod' was written for him. His publications include 'The Imaginative Faculty,' delivered as a lecture before the Royal Institution (1893); and other lectures on 'Hamlet from an Actor's Prompt Book'; 'Henry VIII and His Court'; 'Thoughts and Afterthoughts' (1913); 'Nothing Matters' (1916), etc. He received the honor of knighthood in 1909.

TREE-CAT, a palm-civet. See PALM CAT.

TREE-CREEPER, a bird (*Certhea*). See CREEPER.

TREE-CRICKET, one of the small, almost colorless crickets of the genus *Œcanthus*, specifically the snowy cricket (*Œ. niveus*), whose two-syllabled rhythmic night-song is one of the most familiar summer noises of eastern America. This song varies greatly in pitch and rapidity according to the temperature and other conditions. In the day-time the insect trills in a different voice. Consult Howard, 'The Insect Book' (New York 1901), wherein will be found extensive references to other works.

TREE FERNS. See FERNS AND FERN ALLIES.

TREE-FROG, or **TREE-TOAD,** a frog of the family *Hylidæ*, distinguished from common frogs (*Ranidæ*) by having the ends of the fingers and toes dilated into flattened discs or suckers, which enable them to lead their peculiar arboreal life. They are of more elegant form, smaller size, brighter colors and more active habits than the *Ranidæ*, and are lively during the day; they feed on insects, which they pursue on bushes and trees, stealing toward them or suddenly springing and swinging upon them; they climb like geckos, and by the same mechanism; the lower surface of the discs is endued with a viscid secretion, by means of which they can walk with the body suspended from the under parts of leaves and other smooth bodies; the skin is mostly smooth upon the back, but on the abdomen and inside of legs thickly studded with small warts or tubercles. They possess to a remarkable degree the faculty of changing color, by the modifications of the contents of the pigment cells under the skin (see CHROMATOPHORES), no doubt a provision to enable them to elude their numerous enemies. They are very clamorous, and particularly noisy at the approach of rain. In winter they bury themselves in the earth or in the decayed wood and dust of old stumps. They breed in the spring, depositing their eggs in the water. The species are numerous, especially in tropical America.

The common tree-frog of North America (*Hyla versicolor*) resembles a toad in form, but is more flattened; body short and warty above, the color varying from pale ash to dark brown, with several large irregular blotches of greenish brown, white and granulated below, and abdomen yellowish near the thighs; the colors vary at the will of the animal. The head is short and rounded, the mouth large, with teeth on upper jaw and vomer; eyes large and brilliant, the iris bright golden; there are four fingers and five toes, both ending in viscous pellets, the former distinct, but the latter webbed. It is about two inches long, and is found abundantly as far west as the Mississippi, on decaying trees and about old fences of wood or stone, the color of which it nearly resembles. It is very noisy in spring and summer toward evening, especially in cloudy weather, and its cheerful and abruptly terminating note must be familiar to all residents in the country. This species in the Southern States is replaced by the green tree-frog, which is bright green above, yellowish white below, with a straw-colored lateral line extending from the upper jaw over the shoulder and along the side; it is shorter and more slender than the northern species, and is most commonly seen about broad-leaved plants, especially Indian corn, the color of the leaves of which it greatly resembles, concealed during the heat of the day, but coming out morning and evening and becoming very active and noisy; the single note is clear and bell-like. The tree-frog of Europe (*H. arborea*) much resembles this. Several other species occur in the Southern and Southwestern States. In the genus *Acris* the locomotive discs are less developed and the limbs more slender than in *Hyla*, and there are teeth on the palate instead of the vomer. The *A. gryllus*, or cricket, is about one and one-half inches long, with an elongated pointed head, a triangular dusky spot between the orbits; body ashy above, with a green and sometimes reddish dorsal line, and three oblong black spots margined with white on the sides. It is a lively species, constantly chirping like a cricket, even in captivity. In the genus *Hylodes* the palate is toothed, and the slender fingers and toes are free, with small discs. Pickering's tree-frog (*H. pickeringii*) is nearly an inch long, with short head and yellowish brown body, with dusky rhombodial spots and lines, sometimes like the letter X on the back; pale flesh-colored below, tinged with yellowish on the throat. This is the true peeping frog, the noise being made by both sexes; in summer they cease to be vocal, retiring from the pools where the eggs were laid to the woods, where they live on trees, hopping about on the branches in search of insects and occasionally uttering a shrill whistle.

Many strange variations in breeding-habits and rearing of young characterize the tree-frogs of tropical America, which exist in a great number of genera and species. A famous South American species is the ferreiro (*H. faber*), which makes small pens or nurseries under water in which its eggs are left to hatch, and where the tadpoles are confined, protected from many dangers. Another species (*H. goeldii*) carries its few large eggs on its back until they hatch, and the young remain some time afterward. The genus *Nototrema* develops pouches in the skin of the back of the female in which the eggs and young are safely transported. Ex-

tensive information and guidance to further facts may be found in the 'Cambridge Natural History' (Vol. VIII, London 1901).

TREE-KANGAROO. See DENDROLAGUS; KANGAROO.

TREE-PORCUPINE, or **COUIY,** a South American arboreal porcupine (q.v.) of the genus *Cercolabes* (or *Sphingurus*), characterized prominently by the long, naked prehensile tail. There are several species, all small and short-spined.

TREE-RAT, a small East Indian rat (*Mus arboreus*), common in Bengal. It builds a nest in cocoanut trees and bamboos, and lives partly on grain and partly on young cocoanut.

TREE-SHREW, or **BANXRING,** a small squirrel-like insectivore of India and the Malay Archipelago, the several species of which constitute the family *Tupaiidæ*. The fur is soft and glistening, and a long, bushy tail is generally present. They are restlessly active during the day, searching for insects and fruits, both on the ground and in trees. Two of the largest species are the tana (*T. tana*), with a feathery tail, in one variety of a bright, golden color; and the ferruginous banxring (*T. ferruginea*), widely distributed in the Malayan region. The soles of the feet in the latter are plaited like those of geckos and give the animals a sure grip of a branch. Consult Blanford, 'Mammals of India' (London 1888).

TREE-SPARROW. See SPARROW.

TREE-TOAD. See TREE-FROG.

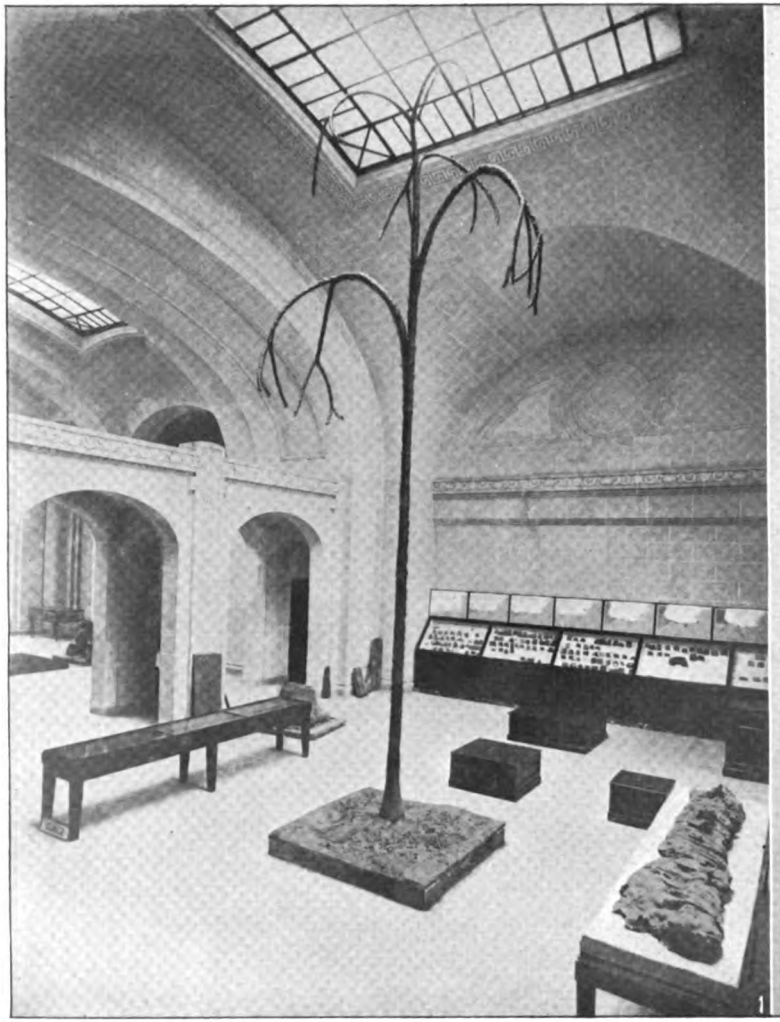
TREE OF TULE. Among the big trees of the world, the best known are the Sequoias, or Giant Redwoods of California, which reach a diameter of 36 feet and a height of 279 feet. Not so widely known, but equally tall, are the Eucalyptus trees of southeastern Australia. The Banyan trees of India cover more space, but these are more like a grove than a single tree. The Big Tree of Tule may fairly claim to be the largest tree in the world. Tule is about 360 miles south of the City of Mexico and just a few miles south of Oaxaca, on the stage road between Oaxaca and the Ruins of Mitla. The tree is about 50 feet in diameter — Campbell's guide book gives the circumference as 154 feet and two inches at six feet from the ground — and the height is a little more than three times the diameter of the trunk, so that in general appearance it resembles a gigantic willow. A common name for the tree is The Montezuma Cypress. The scientific name is *Taxodium mucronatum;* consequently, it is closely related to the Swamp Cypress, or Bald Cypress (*Taxodium distichum*) of the southern United States. The Montezuma Cypress was once abundant in Mexico and many of the trees were very large, but, even in the time of Cortez, the Big Tree of Tule was famous as the largest of all living things. Humboldt carved on the trunk an inscription which is now so overgrown that only the beginning and end of the lines can be read. The government — at least until 1912 — recognized the tree as a wonder and kept guards to preserve it against the ravages of tourists. Estimating the age by the annual growth rings and assuming that the growth rings of the big tree are of about the same width as in other large trees of the same species, the Big Tree of Tule must be at least 5,000 years old. The famous Tree of the Sorrowful Night — Arbol del Noche Triste — in the City of Mexico, the tree under which Cortez rested after his worst defeat at the hands of the Aztecs, belongs to the same species.

TREE WORSHIP. The worship of a tree as in itself divine does not appear to have prevailed in any age of the world. In the mythology of ancient Greece and Rome, trees were regarded as the abodes of sylvan deities, supernatural beings, inferior to the gods of Olympus. Even where this view was not taken, and the tree was not venerated as the dwelling-place of divinity, trees were associated with the worship of the gods, and a certain degree of sanctity attached to them. This association was so strong and to the popular view so indissoluble, that to destroy a grove in which a god was worshipped was to put an end to the worship at that particular spot. Bible statements (1 Kings xv, 13, 14 and other places) show that the removal of an idol, while the grove remained, was not sufficient to put a stop to idolatry. The sacred groves were also an essential feature of Druidical worship. It should be remembered that, while the philosophers and other learned men of ancient Greece and Rome looked upon the current mythology with incredulity, if not contempt, the great mass of the people, and in particular the peasantry, were deeply devoted to it, and to them the sacred groves, the dryads, fauns and satyrs were very real.

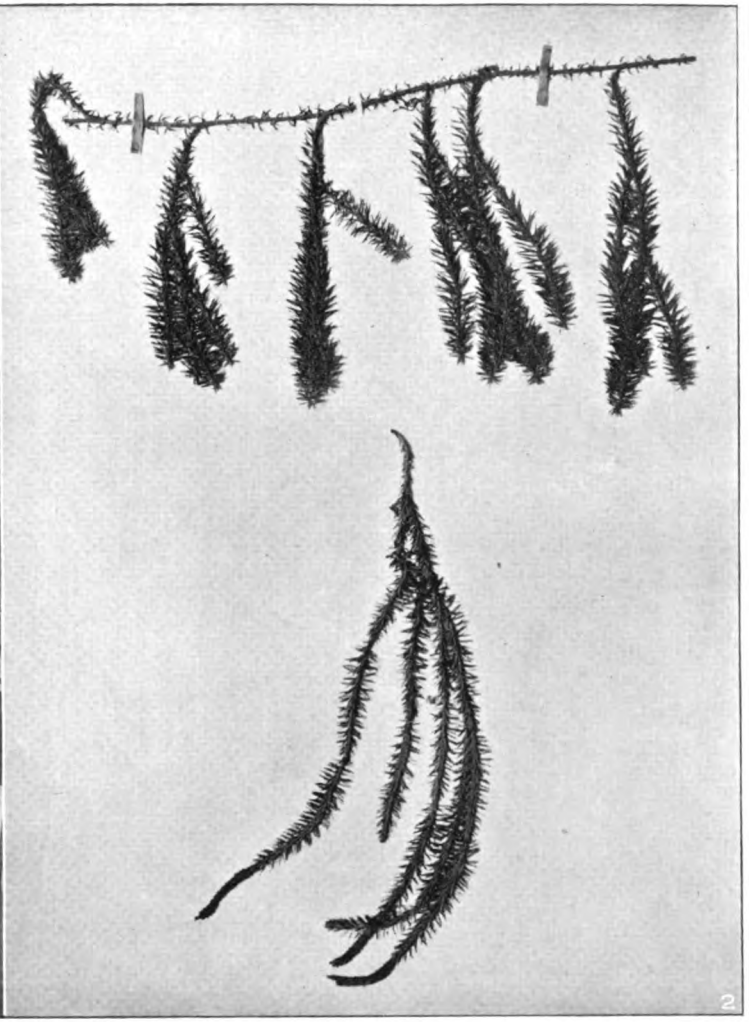
Tree worship, or anything resembling it, has no place in any branch of Christianity, and among Christians the attachment to trees, or any particular tree, is entirely a matter of natural sentiment. There is nothing of the kind in Mohammedanism, and the sacred literature of Buddhism attaches no sanctity to trees. Nevertheless, before the destruction, in October 1887, of the Bo tree, grown from a branch of the tree sent by Asoka, king of Maghada, and famous as a devotee of Buddhism, to Ceylon, in the 3d century B.C., thousands of pilgrims visited the tree annually and offered up prayers before it. This cannot be called tree-worship in the ancient meaning of the term. It is true, nevertheless, that the early Buddhists regarded certain trees as sacred, and much time elapsed before members of that faith got rid of their old superstitions in this respect. Those superstitions still prevail among the more barbarous races, and some of the Greek Christians in remote districts are said to mingle pagan worship of tree-gods with their nominally Christian practices.

TREFOIL, any of several plants having trifoliate leaves, as clover, etc., especially bird's-foot (q.v.), a legume of the genus *Lotus* (q.v.). *In architecture,* a three-lobed ornament, forming a conventionalized figure of three leaves, used in tracery, panels, windows, etc. Also *in heraldry,* a bearing or charge representing a conventional triple clover-leaf, always accompanied with its slip or stalk. It signifies fidelity.

TREGEAR, Edward, Australian author: b. London, 1 May 1846. He went to New Zealand in 1863, where he served in the Maori War and other military work. Later he became gold fields surveyor at Coromandel and



1 The oldest tree in the world. A giant Club-moss (Lepidodendron) flourished in Devonian times (q. v.). Restored, natural size, from only known fossil, found in New York State, and now in New York State Museum



2 Specimens of Club-moss (Lycopodium q. v.) the present living representative of the Devonian giant

Thomas, and surveyor of native lands. He organized the Labor Department of the New Zealand government in 1891; and he was decorated by the French government in 1896. Among his published works are 'The Maori Polynesian Comparative Dictionary'; 'Fairy Tales of New Zealand and the South Seas'; 'The Maori Race'; 'A Dictionary of the Mangareva'; 'A Dictionary of Niue.'

TREGELLES, trĕ-gĕl'ĕs, **Samuel Prideaux,** English Biblical scholar: b. Falmouth, 30 Jan. 1813; d. Plymouth, 24 April 1875. Early in life he worked in the iron foundries at Glamorgan, and by himself studied the classical and Oriental languages. In 1837 he settled in London, where he superintended the publication of the 'Englishman's Greek Concordance to the New Testament' (1839) and the 'Hebrew and Chaldee Concordance to the Old Testament' (1843). In 1838 he began the critical study of the New Testament, and formed the design of a new Greek text derived from a comparative study of ancient manuscript. With this end in view he made several visits to the Continent, spending five months in Rome, where he discovered some important readings in his examination of Codex B in the Vatican, which manuscript, however, he was not allowed to copy. He published his 'Account of the Printed Text of the Greek New Testament' in 1854, and in 1857 began the publication of the first part of the Greek Testament, comprising Matthew and Mark. The remainder of the gospels and the epistles were published from time to time until 1870. The 'Revelation' was edited from his notes by S. J. Bloxidge and B. W. Newton in 1872, and in 1879 Dr. Hart published his materials for the prolegomena in an appendix to the Greek Testament. Others of his works are 'Defense of the Authenticity of the Book of Daniel' (1852); 'Collation of the Texts of Griesbach, Scholz, Lachmann and Tischendorf, with that in common Use' (1854); and the 'Codex Lacynthius, Fragments of Saint Luke' (1861).

TREITSCHKE, Heinrich von, German historian: b. Dresden, 15 Sept. 1834; d. Berlin, 28 April 1896. He was educated at the universities of Bonn and Leipzig and early advocated a German union in his writings. In 1858 he was appointed lecturer in history at the University of Leipzig and became the most popular teacher at that institution. He also became known to the general public through a series of lectures on the constitutional history of Germany. He was a close student of the political trend in Germany and in 1864 he advocated a German union under Prussian leadership. About 1865 he was appointed to a lectureship at Freiburg, but he resigned the following year to become editor of the *Preussische Jahrbücher.* His strong and sometimes violent opposition to modern liberal tendencies in government led to frequent bickerings with Brentano, Schmoller and other economists and led to his resignation. He was next at the University of Kiel, at Heidelberg in 1867–73, and after 1873 held a chair at the University of Berlin. After the formation of the empire in 1871 Treitschke was elected to the Reichstag. At first a National Liberal he became ever more and more conservative. His uncompromising Germanism caused him to make violent attacks on all opinions and all party groups in which he saw something injurious to the rise of the German Empire. He was now one of those who sang the praises of the Hohenzollerns and in the days of the Kulturkampf he ably supported the government. Treitschke attacked the Ultramontanes, the Socialists and the Jews. In Great Britain he saw the chief obstacle to German imperialism and colonial expansion. He was responsible for most of the anti-British feeling in Germany in the last decade of his life. In England he remained comparatively unknown, until the outbreak of the war in 1914 caused renewed discussion of Germany's political thought in the closing quarter of the 19th century. His writings were now translated and extensively circulated. Treitschke was attacked as one of the instigators of the war; his anti-English utterances were quoted in proof of the allegation that he foresaw an unavoidable conflict between the two countries.

As a historian Treitschke is highly regarded. His especial claim to fame is his 'Deutsche Geschichte im neunzehnten Jahrhundert' (5 vols., 1874–94; English translation, 7 vols., New York 1915 et seq.). This work was incomplete at the author's death, ending with a discussion of the events preceding the Revolution of 1848. This history is one of the classics of Germany because of its power of style, skilful character delineation and vigorous narration. Its faults are discursiveness, bad arrangement and extreme partisanship. Other works are 'Zehn Jahre deutscher Kämpfe, Schriften zur Tagespolitik' (1874; 3d ed., 1897); 'Der Sozialismus und seine Gönner' (1875); 'Der Sozialismus und der Meuchelmord' (1878); 'Ein Wort über unser Judentum' (1880); 'Historische und politische Aufsätze' (1865; 1870; 1897); 'Zwei Kaiser' (1888); 'Politik,' collected lectures on political subjects (2 vols., 1907); 'Ausgewählte Schriften' (2 vols., 1907). Selections from the 'Politik' have appeared in English (London 1914). There is in English a collection of Treitschke's essays between 1871 and 1895, entitled 'Germany, France, Russia and Islam' (London 1915). Consult Davis, H. W. C., 'The Political Thought of Heinrich von Treitschke' (1915); Schiemann, T., 'Heinrich von Treitschkes Lehr. und Wanderjahre' (2d ed., Munich 1898); Hausrath, A., 'Zur Erinnerung an Heinrich von Treitschke' (Leipzig 1901); id., 'Treitschke, His Doctrine and His Life' (New York 1914); McCabe, Joseph, 'Treitschke and the Great War' (New York 1914); McClure, E., 'Germany's War Inspirers' (New York 1915); Mügge, M. A., 'Heinrich von Treitschke' (New York 1915).

TRELEASE, William, American botanist: b. Mount Vernon, N. Y., 22 Feb. 1857. He was graduated at Cornell University in 1880 and took his degree as Sc.D. at Harvard in 1884. He was in charge of the Summer School of Botany in the later institution (1883–84); was lecturer on botany in Johns Hopkins (1884); director of the Missouri Botanical Garden (1889–1912), and since 1913 has been professor of botany in the University of Illinois. He is a member of various learned societies, the editor of several botanical works and author of numerous reports on botanical and entomological subjects.

TRELLIS, a frame composed of crossed bars or latticed and used for many purposes.

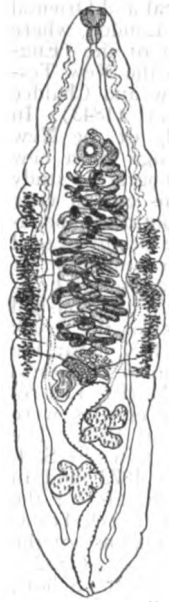
The French espalier is a kind of trellis made of larch wood about shoulder-high on which shrubs, flowers, vines, roses, etc., are trained and supported.

TRELLISED DRAINAGE, also known as LATTICED DRAINAGE, is a drainage network in which there is a notable tendency for the larger streams to occupy parallel courses, with the tributaries notably at right angles or nearly so. This may be caused by parallel series of faults or joints which control the courses of the streams. More often, however, it occurs in regions like the Appalachians, where the rocks consist of alternating hard and soft beds tilted up on edge. The streams may at first occupy any position, but those on the softer rocks develop more rapidly than the others and finally capture their less favored neighbors until all the larger rivers occupy parallel courses on the soft beds. At a few points the large streams break across the hard rock ridges and at these points the valleys become notably narrower, forming narrows or water gaps. When as a result of piracy such water gaps loose their streams they are called wind gaps. Contrasted with trellised drainage is the branching, tree-like pattern developed on flat-lying beds or on homogeneous rocks and known as dendritic drainage. See STREAM PIRACY; and the section on *Work of Running Water* in the article on GEOLOGY.

TREMAIN, Henry Edwin, American soldier: b. New York, 14 Nov. 1841. He was graduated from the College of the City of New York in 1860, served in the Union army 1861–66, rising from the grade of private to brigadier-general of volunteers, and for conduct at the battle of Resaca, Ga., 15 May 1864, he was awarded a Congressional medal of honor. After the war he pursued the study of law and was graduated from the Columbia Law School in 1867. He was United States attorney of New York in 1873–77, and has since engaged in law practice. He is active in political matters, prominent in various military organizations of the veterans of the Civil War and has published 'Sailor's Creek to Appomattox Court House, or the Last Hours of Sheridan's Cavalry' (1885).

TREMATODA, or FLUKES, a prominent class of the branch or phylum Plathelminthes of consistently parasitic habit. The simple body, the presence of an alimentary canal and even of some special sense organs together with the occurrence in most cases of free living stages in development shows that the trematodes stand much nearer free living forms like the Turbellaria than do the cestodes. Furthermore, while the majority of flukes are endoparasitic there are also ectoparasitic species which display considerable freedom and not only pass from host to host but have an extended period of free existence before they assume the parasitic life.

Trematoda are generally flattened and elongate though some are conical, cylindrical or irregular in form. The mouth is mostly at or near the anterior tip of the body and the excretory pore near the posterior end. Highly developed muscular suckers are found at the anterior end on the ventral surface or at the posterior end. The ectoparasitic species have commonly chitinous hooks or anchors in connection with the suckers to serve as additional organs of attachment. Many species are more or less covered with minute scales or spines. Trematodes vary in size from 0.2 mm. to 25 or rarely 75 mm. in length. The body is solid as parenchymatous tissue fills all the space between the organs. The alimentary system is either rodlike (rhabdocoel) or shaped like a tuning fork (triclad). In some of the larger forms it possesses lateral branches which may assume a complex aspect. There is no skeletal system but muscular layers of circular, longitudinal and diagonal fibres lying near the surface of the body form the main part of the dermomuscular sac. By virtue of this excessive muscular development the flukes are extremely mobile and variable in form. Stellate flame cells terminating in minute tubules constitute the elements of the excretory system which varies in complexity with the size of the organism.



Opisthorchis felineus, from liver of man. Europe. (Original drawing from type specimen.)

The reproductive system comprises with rare exceptions the organs of both sexes. The male organs are rather simple, whereas the female system is very complex. The parts and their relations are very similar to those found in cestodes. The development of trematodes is direct and simple among the ectoparasitic forms but complex among endoparasites where it is complicated by alternation of generations and one or more changes of host. In the common sheep liver fluke which presents a life cycle of moderate complexity, a minute ciliated embryo escapes from the egg shell whenever this is carried by chance into a water body. The little free swimming larva (miracidium) seeks out a snail and in its liver tissue metamorphoses into a sac (sporocyst) in which is developed a new generation (redia). Within these individuals are produced similar forms or when conditions are favorable a modified type (cercaria) which deserts the snail and encysts on grass or in the water. This form is really the young distome and it attains the stomach of the sheep with food or drink. There set free by digestion, it wanders into the liver and by growth becomes adult. Even more complex conditions are found in other species; the most if not all endoparasitic trematodes agree in selecting a mollusk as an intermediate host and in manifesting alternation of generations.

Several species are of great economic importance; thus the sheep liver fluke (*Fasciola hepatica*) produces epidemics of liver rot of great magnitude, entailing large annual losses to sheep raisers in England, Australia and on the Continent; the loss in extreme instances has reached $20,000,000 in a single year.

About a dozen species of fluke are known as human parasites. The Asiatic lung fluke (*Paragonimus westermani*) is very abundant in

the East (Japan, China, Formosa and the Philippines) and produces a disease resembling tuberculosis. A related species has been reported from a few localities in the United States. The Chinese intestinal fluke (*Fasciolopsis buski*) though formerly believed to be rare, is now known to be exceedingly abundant in some parts of China, Siam, etc. It gives rise to serious intestinal troubles.

The human liver fluke (*Clonorchis sinensis*) is very abundant in some parts of China and Japan and has frequently been introduced into this country. The human blood fluke has three species; *Schistosoma hæmatobium* which has been identified in Egyptian mummies of the 20th dynasty (1250 B.C.) and is exceedingly common in that and adjacent regions to-day. *Sch. japonicum*, endemic in parts of Japan, China and the Philippines; *Sch. mansoni*, reported first from the West Indies, and known to occur in Central and South America and in the Kongo Basin, Africa. It was very likely introduced into this continent by the slave trade. All species are the cause of serious circulatory, renal and intestinal disturbances. The eggs are evacuated either with urine or feces and are distinguished in that the Egyptian form possesses a terminal spine, the Japanese form is spineless and the form from the West Indies has a lateral spine on the egg. The disease produced by the first species has long been known as Egyptian hæmaturia. For further data consult Fautham, Stephens and Theobald, 'Animal Parasites of Man' (London 1916); Ward, H. B., 'Trematoda in Reference Handbook of Medical Sciences' (New York 1917).

HENRY B. WARD,
Professor of Zoology, University of Illinois.

TREMOLITE, a white or gray variety of amphibole. It occurs abundantly either in distinct crystals or in columnar or fibrous masses. It is essentially a calcium and magnesium metasilicate, being distinguished from the other varieties of the mineral by its pale color due to the absence of iron.

TREMULANT, a draw-stop in a pipe or reed organ which regulates a mechanical device consisting of a thin metallic plate so arranged as to modify the admission of wind into the pipes, and by its vibrations produce a sweetly tremulous or waving effect, presumably imitative of the *vox humana*, or human voice. Young organists usually have to be warned against the overuse of this device.

TRENCH, Herbert, British writer of poems and plays: b. Avoncore, County Cork, Ireland, November 1865. He was educated at Oxford and was a Fellow of All Soul's College; became examiner at the Board of Education (1891); then traveled extensively abroad and was director of the Haymarket Theatre where he produced Shakespeare's 'King Lear' and Maeterlinck's 'The Blue Bird.' He was founder of the British Institute in Florence, where he drew up the scheme for producing a better understanding between Great Britain and Italy (1918). He published 'Deirdre Wedded and Other Poems' (1901); 'Lyrics and Narrative Poems' (1911); 'Napoleon,' a play (1918), etc.

TRENCH, Richard Chenevix, Irish prelate, archbishop of Dublin; b. Dublin, 9 Sept. 1807; d. London, 28 March 1886. He was educated at Harrow and Trinity College, Cambridge, where he was graduated in 1829. His college friends included Tennyson, Hallam, Maurice, Sterling and Kemble. Ordained in 1832, he became curate at Hadleigh, in Suffolk, in the following year. He took priest's orders in 1835, and held the curacy of Curdridge, Hampshire, during 1835–41. After a few years as curate at Alverstoke, in Hants, he obtained the rectory of Itchenstoke, in 1844. He became examining chaplain to Bishop Wilberforce of Oxford in 1845, and professor of divinity in King's College, London, the next year. The latter post was held by him till 1858, and during 1856–63 he was dean of Westminster. He was consecrated archbishop of Dublin on the first day of 1864. He resisted the disestablishment proposals of Gladstone, but accepted the new conditions loyally. He resigned the see in 1884. He was buried in Westminster Abbey. Trench was known as a poet by many sonnets, lyrics and other verses published in the following, among other volumes: 'The Story of Justin Martyr, and other Poems' (1835); 'Poems from Eastern Sources' (1842). His contributions to philological subjects include 'The Study of Words' (1851); 'English, Past and Present' (1855); and 'A Select Glossary of English Words' (1859). His Biblical and theological works comprise 'Notes on the Parables of our Lord' (1841); 'Exposition of the Sermon on the Mount' (1844); 'Christ the Desire of all Nations' (1846); 'Studies in the Gospels' (1867), and many volumes of sermons. He was a member of the committee for revising the New Testament. Among his other publications are 'Sacred Latin Poetry' (1849); 'A Household Book of English Poetry' (1868); 'Plutarch: his Life, his Lives, and his Morals' (1873); and 'Lectures on Mediæval Church History' (1877). Consult 'Letters and Memorials of Richard Chenevix Trench' (1888).

TRENCH, Military. See FORTIFICATION; TRENCHES.

TRENCH MORTAR. See GUNNERY.

TRENCHARD, trĕn'chard, **Stephen Decatur,** American naval officer: b. Brooklyn, N. Y., 10 July 1818; d. New York, 15 Nov. 1883. He was appointed midshipman in the navy in 1834, served in the Seminole War, was on the coast survey in 1845–46 and in 1847 was promoted lieutenant. He was engaged on board the *Saratoga* in the war with Mexico, was attached to the coast survey in 1853–57 and in 1857–60 served on the *Powhatan* on her diplomatic cruise to China and Japan. He was promoted commander in 1862, participated in both attacks on Fort Fisher and in 1866 received rank as captain. In 1871 he was promoted commodore, served on the examining board in 1871–72 and as lighthouse inspector on headquarters duty in 1873–75. He was advanced to the rank of rear-admiral in 1875 and in 1876–78 was in command of the North Atlantic squadron. He was retired in 1880.

TRENCHES. An entrenched zone consists of an entire system of trenches and their auxiliaries, composed of wire entanglements and other obstacles, listening posts, lookouts, machine-gun emplacements, fire trenches, communicating trenches, trenches for reserves and

supports, command posts, cave shelters, latrines and the like, occupied or susceptible of being occupied by a firing line and by its supports and local reserves.

Firing trenches are those designated primarily for delivering rifle fire against an infantry attack and are usually constructed in short lengths for a squad, section or platoon, arranged so that they are mutually supporting and thoroughly cover the ground by both frontal and flanking fire. If longer than required for a squad they should be of an irregular or indented trace and be traversed at intervals of from five to eight yards so as to give protection from enfilade fire and localize the effect of shell bursts.

If the firing trenches are located under fire when an attack has been halted the location is determined by the line at which the troops are forced to halt, and dig themselves in. This line may in some cases be a hostile trench captured in the course of the attack. Ordinarily each man will construct individual cover in the form of a lying trench, which he will gradually improve to a sitting, kneeling or standing trench. Small adjustments of position may be made by the officers with a view to getting the best possible line under the circumstances. The individual pits are connected up into squad or longer length when night falls, and the trace and location can then be rectified.

If the enemy has been found in a strong defensive position and an attack has not been made, or has resulted in a withdrawal, a line of firing trenches may be located under cover of night from 500 to 600 yards, or even more from the enemy, the exact distance depending upon the ground, the facilities for natural cover and the tactical condition. This line may be made fairly strong and complete before any further advance is attempted. Then under cover of darkness or fog, or a heavy bombardment, a new firing trench may be constructed at a distance of 200 to 300 yards from the enemy.

When not in the presence of the enemy a careful reconnaissance should first be made and the firing trenches can then be located with due regard to the terrain, the tactical requirements and economy of men.

The following general rules should govern the location of the firing trenches: (1) The field of fire should be such as to expose an attacking enemy to fire for at least the last 200 to 300 yards of his advance. To ensure this it may be necessary to clear the foreground. With well-trained troops a shorter field of fire may be sufficient, provided it is covered by frontal and flanking fire and is strengthened by a good obstacle, which should be well screened from the distant view of the enemy. (2) Concealment of the trenches is of the greatest importance. (3) The defenders should be screened from the enemy's view and sheltered from his fire by natural or artificial cover so arranged as to afford the maximum development of rifle fire. (4) The foreground should contain natural obstacles to break up the formations of attacking troops, but not afford them cover. (5) There should be good communications within the position and over ground that may be used for counter-attacks. (6) The trenches should not be placed too near unalterable features that reveal their location or furnish good range marks for the enemy. (7) The location of firing trenches on the crest or forward slope, though exposing them to view and bombardment, gives a feeling of superiority to the troops and increases their morale; enables the support, reserve, communicating and approach trenches to be well concealed; offers greater facilities for observation and for the assembly of troops for the assault close to the firing trenches and unobserved. (8) The location of firing trenches behind the crest of a slight ridge screens them from view and fire of the enemy's artillery, unless he has in his possession high ground giving a view of the reverse slope. Special conditions, such as the enemy's local superiority in artillery, may justify the deliberate choice of such a position, but it must not be too far down the reverse slope, arrangements must be made to deny the enemy access to the crest of the ridge and there must be a number of saps forward to the crest to allow a continuous observation of the front slope. (9) In woods the trenches should be located 10 to 20 yards from the front edge; the natural appearance of the woods should not be changed, but a clear field of fire obtained by cutting some of the brush, small trees and low branches.

Frequently trenches designed primarily for other purposes (such as cover trenches, communicating trenches, approach trenches) are in places prepared for occupancy by a firing line, with appropriate banquette, etc. Sometimes approach trenches may be prepared for firing in both directions. These are not firing trenches, as their use for firing is secondary.

Cover trenches are from 10 to 100 yards in rear of the firing trenches, to protect men of the firing line (except firing trench guards) during all but the infantry attack. It is not advisable to occupy firing trenches in force except when they are attacked by infantry. The bulk of the firing line should, therefore, be close at hand under cover, and to a certain extent the trenches which afford this cover facilitate lateral communication. They are often not continuous, and there obtains with them also the tactical requirement of dispersal. Cover trenches are amply provided with cave shelters, bombproofs and the like, and in places with firing banquettes, overhead cover and loopholes, or head cover. From the cover trenches, approach trenches proceed forward at frequent intervals to the communicating trenches or firing trenches. Usually at less frequent intervals are approach trenches entering the cover trenches from the rear.

Communicating trenches are deep trenches used to afford proper lateral communication. They are frequently of short lengths, in front or in rear of the general line of the cover trenches, and generally opposite intervals between such trenches. Portions of the communicating trenches are prepared for fire and local supports may be sheltered in portions of them. Communicating trenches and cover trenches are connected by approach trenches; and where communicating trenches are in advance of cover trenches they are connected with the fire trenches by approach trenches relatively close together.

Approach trenches are those enabling one to pass within the intrenched zone from front to rear or vice-versa between firing trenches, cover

trenches, communicating trenches and other parts of the trench system farther in rear. Portions of approach trenches are prepared for firing, sometimes in both directions. They are deep, comparatively wide and winding, traversed or zigzagged.

Local trenches extend to observation stations, command posts, latrines, machine-gun emplacements and the like from firing, communicating, cover or other trenches.

over the parapet with proper effect so he can hit the bottom of his own wire entanglement. Traverses must be adequate. A parados must be provided to give protection against the back blast of high explosive shell; the trace of the trench should be irregular, to provide flanking fire; and if the trench is to be held for any length of time, the sides must be revetted and the bottom of the trench must be floored and drained. The drawings show the trench pre-

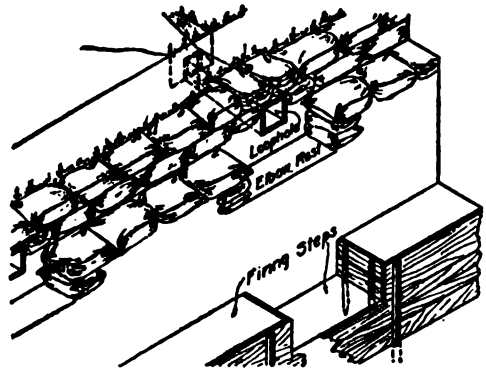
Long Range Searching or Barrage Fire and Profile of Trenches.

Support trenches are designed to shelter all of the troops who form the local supports of the firing line during hostile artillery fire, and a portion of them during the period of the infantry attack, if all are not then required farther forward. They are ordinarily similar in type of construction to cover trenches, but are located farther to the rear. Toward the front they merge into the cover trenches. Toward the rear they may be as remote from the firing trenches as 200 or 275 yards. Approach trenches provide communication from them to front and rear. Support trenches are sometimes provided with firing banquettes and the like, and machine-gun emplacements may be located among them. Often the ground is such as to permit the supports to occupy naturally sheltered positions, where support trenches may be much modified or omitted in places altogether.

Reserve trenches are trenches designed to shelter the local reserves. They are in rear of the support trenches, but often merge into them toward the front. While the firing trenches hold, reserve trenches are not ordinarily subjected to prolonged and severe artillery fire.

Every firing trench should fulfil the following essential conditions: The parapet must be bullet proof; every man must be able to fire

pared for firing through and over the parapet and typical sections for long range searching or barrage fire. The narrower the trench, the better the cover; but if too narrow it may hamper



Trench for Fire through and over the Parapet.

the movement of troops too much. Therefore, a firing trench is usually made broad enough to allow of movement behind the line of men manning the parapet. Every man must be able to use his rifle over the parapet, and the men

moving behind must not have to stoop down in order to get their heads under cover.

The resulting section is, therefore, with a banquette or firing step 18 inches wide and four feet six inches (or five feet, if we allow for a small notch or hollow to hold the rifle) below the crest of the parapet, and behind this a deeper portion from 18 to 30 inches wide at the bottom and from six to seven feet below the crest line of the parapet. The firing step must have a level surface to give a firm foothold. It may consist of an earth step revetted with planks held in place by stakes.

The best type appears to be a trench with a firing banquette for five or six rifles in each bay, between two traverses, each six feet thick, and with the back part of the excavation formed into a communicating trench for observation and manning of parapets. This trench is somewhat deeper and three feet wide.

Types of communicating and approach trenches are now becoming fixed. In France the following seem to have been the normal: Communicating and approach trenches well to the rear six feet wide, those farther forward three feet wide and both types six feet eight inches deep. A communicating trench less than three feet wide at the bottom is sure to become jammed. This is the minimum to be allowed, and the work should be commenced with a width of not less than three feet eight inches at the top, so as to get three feet at the bottom, according to the stiffness of the soil.

Berms of one foot on each side of a sap or trench where earth is piled up are considered indispensable. They prevent sliding of earth and furnish a little shelf on which to place tools, bags, guns and other articles, in case troops want to pass the occupants; the double berm also makes it possible for infantry to get out of a trench when the emergency requires.

EDWARD S. FARROW,
Consulting Military and Civil Engineer.

TRENCK, trĕnk, BARON **Friedrich von der,** German adventurer: b. Königsberg, 16 Feb. 1726; d. Paris, 25 July 1794. His life was a succession of adventures scarcely less marvelous than the romantic and highly colored account he gives of them. He entered the Prussian service in 1740 and stood high in Frederick the Great's favor, until, supposedly through his love affair with the king's sister, he incurred the royal displeasure, which caused his first imprisonment, the beginning of no end of misfortunes; loss of property, numerous imprisonments and attempts at escape, dangerous wounds and perils of all kinds. The stories of how he broke out of several famous prisons are all most graphically described in his 'Selbstbiographie' (1787), and in one or more very popular English translations which have delighted the youth of four generations. All his wonderful adventures are told in a manner that reminds one of Munchausen's marvelous tales. The anecdotes interspersed give a vivid picture of the turbulent condition of court life at the time of Frederick the Great and Maria Theresa. His restless, adventurous temperament led him to Paris, when the Revolution was in full swing; he was there accused of being a secret emissary of foreign powers, and was beheaded by Robespierre's order. Consult Wahrmann, 'Friedrich Freiherr von der Trencks Leben, Kerker und Tod' (1837). His cousin, BARON FRANZ VON TRENCK, an equal hero and swashbuckler, has also written an autobiography (1748), which, however, has not attained the celebrity of the other's wonderful mixture of fact and imagination.

TRENDELENBURG, trĕn'dĕ-lĕn-boorg, **Friedrich Adolf,** German philosopher: b. Eutin, Germany, 30 Nov. 1802; d. Berlin, 24 Jan. 1872. He studied in Kiel, where he came under the influence of John Erich von Berger, and acquired his early philosophical training at Berlin, and was appointed professor in the university of that city. His writings embrace the whole field of philosophy, ontological, ethical and æsthetical. He set forth the ethical aspect of his philosophy in the treatise 'The Ethical Idea of Right and Law,' and the æsthetic aspect in 'Niobe' (1846); and 'The Cathedral of Cologne' (1853). He wrote also 'Natural Justice on the Ground of Ethics' (2d ed., 1860). His principal claim to distinction as a thinker rests on his acute criticism of the systems of Kant and Hegel.

TRENHOLM, George A., American merchant: b. South Carolina, 1806; d. Charleston, S. C., 10 Dec. 1876. He was one of the largest dealers in cotton in the South before the Civil War and during the war was engaged in blockade-running, endeavoring to obtain supplies for the Confederates from Nassau. He was appointed Secretary of the Confederate Treasury in 1864, but was taken prisoner later in that year and held until 1865, when he was pardoned by President Johnson.

TRENT, William Peterfield, American man of letters: b. Richmond, Va., 10 Nov. 1862. After study at the University of Virginia and at Johns Hopkins University, he was professor of English in the University of the South (1888–1900) and dean of its academic department (1894–1900). From 1892 to 1900 he was editor of the *Sewanee Review,* and since 1 July 1900 has been professor of English literature at Columbia University. He has published 'Life of William Gilmore Simms' (1892); 'English Culture in Virginia' (1889); 'Southern Statesmen of the Old Regime' (1897); 'Robert E. Lee' (1899); 'John Milton' (1899); 'The Authority of Criticism' (1899); 'War and Civilization' (1901); 'The Progress of the United States in the Century' (1901); 'A History of American Literature 1607–1865' (1903); 'Greatness in Literature and Other Literary Addresses' (1905); 'Longfellow and other Papers' (1910); 'Defoe—How to Know Him' (1916), etc. He has also edited 'Select Poems of Milton' (1895); 'Essays of Macaulay' (1897); 'Poems and Tales of Edgar Allan Poe' (1898); 'Balzac's Comédie Humaine' (1900); 'Southern Writers, Selections in Prose and Verse' (1905), and has collaborated in numerous literary undertakings, e.g., 'Colonial Prose and Poetry,' editions of Shakespeare and Thackeray and the 'Cambridge History of American Literature.' Since 1905 his chief work has lain in English history and literature 1680–1730, with special attention to Defoe, of whom he has written a biography and bibliography in 10 volumes still in manuscript.

TRENT (German, TRIENT, trē-ĕnt'), Austria, a town in the southwestern part of Tyrol, of which it is the capital, situated on the river Adige or Etsch, 19 miles northeast of the Lago di Garda. It is a historical city, being the capital of the Trindentini, about the 4th century. It has belonged to Italy, to Venice, Austria, Bavaria, France and again to the Austrian Tyrol. Among its numerous churches the most noteworthy are the cathedral, built in the 13th and 14th centuries in the Byzantine style, and entirely of marble; and the church of Santa Maria Maggiore, in which the meetings of the celebrated Council were held. A statue of Dante was erected here in 1906. The principal manufactures are silk, wine, brandies and sausages. Pop. about 30,000. See TRENT, COUNCIL OF.

TRENT, Canada, a river discharging into Lake Ontario through the Bay of Quinté. The greater part of its course of 175 miles consists of a series of large, irregular and elongated lakes, which have been canalized for a distance of 160 miles. The stream itself furnishes water power, and large quantities of lumber are floated down on it. It passes the towns of Peterborough and Trenton.

TRENT, England, a river rising in Staffordshire, and flowing in a general northeast direction through Derby, Nottingham and Lincoln counties, emptying into the Humber estuary near its head. It is 170 miles long, and navigable 95 miles for small vessels and barges. It is connected by numerous canals with Midland manufacturing cities.

TRENT, Council of. The 19th œcumenical council of the Catholic Church was that of Trent (1545–63). It ranks with Nicæa, Ephesus and Chalcedon as one of the greatest of the general councils. Hitherto the Church had been sundered by schism and riven by heresy in the East. Now the West was in revolt. The deposit of faith had been effectively defended against the onslaughts of Arius, Nestorius, Eutyches and Photius. Now Luther and the Protestant reformers had to be met. So the Council of Trent had a twofold purpose: First, clearly to define the teaching of the Church on the issues that Protestantism had raised; secondly, effectively to legislate against the abuses that had crept in among the clergy and laity. During the pontificate of Clement VII (1523–34), the Emperor Charles V had frequently urged the advisability of a general council as an effective means of stemming the tide of Protestantism. This means was purposed by Paul III (1534–49) from the very outset of his reign. The Pope's efforts were again and again frustrated by the bickerings and rivalry that marked the relations between Charles V and Francis I. So the Council of Trent was not opened until 13 Dec. 1545.

1. First Period (1545–47).— The first formal session of the Council of Trent was attended by the three papal legates — Cardinals Giovanni del Monte, Marcello Cervini and Reginald Pole — 4 archbishops, 22 bishops and 5 generals of religious orders. The right to vote was enjoyed by all of these fathers, though not by the 42 theologians and 9 canonists, who came to the council only as consultors. Paul III was fully aware that political chicanery would prevent many bishops from going to Trent. Yet the prospect of their absence was no hindrance to his determined will to convoke the council. The doctrinal and disciplinary authority of a general council does not depend on the number of the bishops that attend; but, in the last analysis, is consequent upon the infallibility and supreme jurisdiction of the Pope.

A very simple method of procedure was adopted by the council. The cardinal legates proposed the subjects to be discussed: a congregation of theologians drew up an elenchus of doctrines to be defined under each subject; committees and particular congregations debated each doctrine at great length; a general congregation went over the same ground in detail and fixed upon the content and wording of the decree; finally the council in formal session definitively voted on the decree. The thoroughness of this mode of procedure accounts for the long time that intervened between the formal sessions.

The first dogmatic decision of the Council of Trent was given 8 April 1546, in session IV, on Scripture and tradition. It "receives and venerates with equal love and reverence" both Holy Writ and divine tradition; determines the canon of the Bible; selects the Vulgate as the authoritative Latin version, to the exclusion of all other Latin editions of the Bible then current; and defines the right of the Church to interpret the inspired Word of God. In session V, 17 June 1546, Trent decreed the universality of the fall of the human race in Adam, and other doctrines concerning original sin. Then came the important matter of justification. Sixty-one general congregations, besides many committee meetings and special congregations, were devoted to this doctrinal issue and to the reform measures that were appended thereto. On 13 Jan. 1547, in session VI, the masterful decree was passed. It contains a preface, 16 chapters and 33 canons or condemnations Session VII, 3 March 1547, treated of the sacraments in general and of baptism and confirmation. The Smalkald War and an epidemic caused a majority vote of the council, in session VIII, 11 March 1547, to transfer its meetings from Trent to Bologna. Fourteen bishops remained at Trent; they were there detained by Charles V. Indeed, the emperor so interfered with the council that it came to no dogmatic decisions at Bologna, and 13 Sept. 1547 was suspended by Paul III.

2. Second Period (1551–52).— Julius III (1550–55), who as Cardinal del Monte had been first papal legate to the council, reconvened the synod at Trent, on 1 May 1551. His legates were Cardinal Marcellus Crescenzi, Archbishop Pighinus of Siponto and Bishop Lipomanni of Verona. Henry II of France prevented the French bishops from attending. Decrees on the sacraments of eucharist, penance and extreme unction were issued in sessions XIII–XIV. There were now in attendance, 3 legates, a cardinal, 10 archbishops and 54 bishops. Delegates from several Protestant princes were present at these two sessions. They demanded that the council define the supremacy of an œcumenical council over the Pope and postpone definitions on all points of controversy between Catholics and Protestants. The council refused to accede to their demands. Many particular and general congregations were then held in regard to the sacrifice of the mass. No

decree was decided upon. The council adjourned 23 April 1552 because of the nearness of Trent to the war zone of Charles V and Maurice of Saxony.

3. **Third Period (1562–63).**— On the death of Julius III, a former president of the council, Marcello Cervini, was elected Pope (1555); he took the name Marcellus II and reigned only 22 days. Paul IV (1555–59) vigorously carried out the reforms instituted by Trent; but did not reconvene the council. Pius IV (1559–65) was minded to do so. He was deterred by the pettifogging interferences of secular rulers. The Emperor Ferdinand wished a new council and not a continuation of the old; he insisted on the choice of some German city other than Trent as the place of meeting. It took some time to bring him and the rest of the Catholic monarchs to terms. The third period of the council began at Trent 18 Jan. 1562. The president was Cardinal Ercole Gonzaga; his assistant cardinal legates were Stanislas Hos, James du Puy, Jerome Seripando, Louis Simonetta and Marcus Siticus. Besides these legates, there were present a cardinal, 3 patriarchs, 11 archbishops, 40 bishops, 4 abbots and 4 generals of religious orders. The theologians numbered 34.

Bickerings with Emperor Ferdinand and lesser princes delayed the preparation of the decree on holy communion. This decree was most important in its dogmatic and disciplinary bearing. At the formal session XXI, 16 July 1562, the council decided that communion under the form of bread was sufficient for the laity. «For He that said, 'Except ye eat the flesh of the Son of Man and drink His blood, ye shall not have life in you' (John vi, 54), also said, 'If one eat of this bread, one shall live forever' (John vi, 52). And he that said, 'He that eateth my flesh and drinketh my blood, hath everlasting life' (John vi, 55), also said, 'The bread, which I shall give, is my flesh for the life of the world' (John vi, 52). And finally He that said, 'He that eateth my flesh and drinketh my blood, abideth in me and I in him' (John vi, 57), nevertheless added, 'He that eateth this bread shall live forever' (John vi, 59).» Moreover, the council vindicated to the Church the right to determine how the sacraments should be administered; whether, for instance, communion should be under one form or two. Session XXII, 17 Sept. 1562, clearly defined the teaching of the Church in regard to the sacrifice of the mass. Cardinals Gonzaga and Seripando died; they were replaced by the cardinal legates Morone and Navagero. Eighty-four theologians, among them the learned Jesuits Salmeron and Lainez, took part in the preliminary discussions on the sacrament of orders. Session XXIII, 15 July 1563, issued the definitions of Trent on orders and the hierarchy. By this the council had 235 voting members. Session XXIV, 11 Nov. 1563, had to do with the sacrament of marriage. In session XXV, the last, 3–4 Dec. 1563, besides the usual decrees of reform, were promulgated the doctrines of indulgences, and of the veneration of the saints, relics and images. Finally all those decrees were read and approved, which had been passed during the reigns of Paul III and Julius III. These Tridentine definitions were signed by 4 cardinal legates, 2 cardinals, 3 patriarchs, 25 archbishops, 167 bishops, 7 abbots, 7 generals of religious orders and 19 proxies for 33 absentees. Pius IV confirmed the decrees of the Council of Trent, on 26 Jan. 1564, by the bull «Benedictus Deus.»

Bibliography.— The dogmatic decrees of Trent are given in scientific and accurate form by Denzinger-Bannwart, 'Enchiridion Symbolorum' (11th ed., 1911). The classic on the council is being published by a German Catholic publication society, the Görresgesellschaft; the title of this monumental work is 'Concilium Tridentinum: diariorum, actorum, epistularum, tractatuum nova collectio.' Five volumes have thus far appeared: I, *Diariorum* p. 1, the commentary of Hercules Severolus (1901); II, *Diariorum* p. 2, the diaries (1–4) of Angelo Massarelli (1911); IV, *Actorum* p. 1, the acts of sessions 1–111 (1904); V, *Actorum* p. 2, the acts of sessions IV–VIII (1911); X, *Epistularum* p. 1, letters written from 5 March 1545 to 11 March 1547 (1916). The history of the council was written up *a parti pris* by Saroi, 'Istoria del concilio tridentino' (1619). Against him wrote Pallavicino, 'Istoria del concilio di Trento' (2 vols., 1646–57). Other works of moment are Dupuy, 'Instructions et lettres concernant le concile de Trent' (1654); Labbe-Cossart, 'Concilia' (xiv, 1672); Le Plat, 'Monumentorum ad historiam concilii tridentini spectantium amplissima collectio' (7 vols., 1781–87); Theiner, 'Acta geniuna ss. œcumenici concilii tridentini ab A. Massarello conscripta' (2 vols., 1874); Döllinger, 'Sammlung von Urkunden zur Geschichte des Konzils von Trient' (1876); von Sickel, T., 'Zur Geschichte des Konzils von Trient, Aktenstücke aus den österreichischen Archiven' (three parts, 1870–72); Druffel-Brandi, 'Monumenta tridentina' (i–iv, 1884–97); Lainez, 'Disputationes tridentinæ' (ed. Grisar, 1886).

WALTER DRUM, S.J.,
Professor of Scripture, Woodstock College, Maryland.

TRENT AFFAIR, The, in American history, during the Civil War, in October 1861, Capt. Charles Wilkes, United States navy, intercepted at sea the British mail steamer *Trent,* bound from Havana to Saint Thomas, and took off two Confederate commissioners, accredited to France, Messrs. Mason and Slidell, who were among her passengers. They were taken to Boston, and imprisoned in Fort Warren, but were released on 1 Jan. 1862, on the demand of the British government, and permitted to proceed to Europe. Secretary Seward accepted England's demand as an adoption of the American doctrine which denied the right of search.

TRENTE ET QUARANTE. See ROUGE ET NOIR.

TRENTON, Canada, a town and port of entry in Hastings County, situated on both sides of the Trent River at its mouth in the Bay of Quinté, 90 miles northeast of Toronto, and at the junction of the Grand Trunk and Central Ontario railways. It has large manufacturing industries, and an extensive export trade in timber. Pop. 3,988.

TRENTON, Mo., city and county-seat of Grundy County, on one of the forks of Grand

River, and on the Chicago, Rock Island and Pacific and the Quincy, Omaha and Kansas City railroads, about 100 miles northeast of Kansas City, and 80 miles northeast of Saint Joseph. It was established in 1841, in 1857 was incorporated as a town, and in 1893 was chartered as a city. It is in an agricultural and stock-raising region, and nearby is a large coal field. The chief manufacturing establishments are flour mills, butter and cheese factories, cigar factory and machine shops. The shipments are chiefly farm and dairy products, livestock and coal. The educational institutions are public schools, the Jewett Norris Library, which was endowed of $15,000, and school of music and dramatic art. It has municipally owned waterworks, four banks, one national and three State banks with a combined capital of $230,000. Pop. 6,168.

TRENTON, N. J., city, capital of the State, county-seat of Mercer County, on the Delaware River, and on the Delaware and Raritan Canal, on the Philadelphia and Reading and the Pennsylvania railroads, about 59 miles southwest of New York City and 29 miles northeast of Philadelphia. It is in lat. 40° 14′ N., long. 74° 46′ 30″ W. It is at the head of navigation in the Delaware River, and a falls here yields water power. The ground area is nine square miles, and there are about 230 miles of streets. Two bridges cross the Delaware and connect with Pennsylvania.

Manufacturing.— Among the large industrial establishments there are 34 engaged in the manufacture of pottery products, including vitrified china, Belleek china, semi-porcelain, common china, and white granite; also sanitary earthenware, electrical specialties, porcelain bath tubs, vitrified and decorative tiles, terra cotta, drain-pipe and brick. These have made Trenton pottery famous all over the world. Nearly all the clay and all of the coal used in the pottery industry is brought to Trenton. The value of the products amounts to about $7,000,000 per annum, though they have run as high as $12,000,000. Trenton's iron industries (the great works of the John A. Roebling's Sons Company, manufacturing metal wire rope, fire-proof wire, lath, cables, etc., are here) and machine shops produce $5,000,000 per annum. There are 16 rubber works, making a great variety of products, and having sales approximating $30,000,000 each year. Other important manufactures are crackers, school and church furniture works, watches, oil cloth, tobacco goods, carriages and wagons. There are also anvil works, flint and spar mills, lumber yards and fertilizer works. There are about 70 different industries, comprising 540 concerns, representing approximately $50,000,000 capital. There are a total of 3,500 business places in the city.

Public Buildings.— The principal public buildings are the State capitol, the United States government building, municipal and county buildings, opera house, State prison, insane hospital, State home for girls, city library with 40,000 volumes, three hospitals, State arsenal and the Y. M. C. A. building. The Battle Monument, commemorating the battle of Trenton, is conspicuously located, and bears a bronze figure of Washington. The city has a large number of fine church and school buildings and business houses.

Churches and Charities.—The churches and missions in the city number about 75. There are about 15,000 Roman Catholics, 5,000 Methodists, 3,500 Presbyterians, 4,000 Baptists and 2,000 Episcopalians. The members of the Society of Friends, Orthodox and Hicksite, once a power in the community, have dwindled to less than 100. There is a State asylum for the insane, three large hospitals, a Children's Home, the Widows and Single Women's Home, and a number of smaller benevolent and charitable institutions.

Education.— Trenton has a number of noted educational institutions, among which are the State normal and model schools, the State school for deaf-mutes, an industrial school for girls, a large high school, 34 public elementary and primary schools, a school of industrial arts, one Roman Catholic college, eight parish schools, one academy, business colleges and several private schools. Educational classes are conducted under the auspices of the Young Men's Christian Association. There is a free public library, a beautiful white marble building, containing about 75,000 volumes; the State library and several school libraries.

Banks and Finances.— There are eight banks; the combined capital of the three national banks is $1,250,000; the deposits of all except two private banks are $16,622,740. The real estate of Trenton is assessed at over $70,000,000. The cost of city maintenance each year is about $1,650,000. The chief items of expenditure are, for schools, $500,000; for police department, $180,000; for fire department, $170,000; for lighting, $75,000.

Government.— Commission government has been established with five commissioners, having charge respectively of public affairs, revenue and finance, public safety, streets and improvements, parks and public property. The mayor has charge of public affairs and is advisory to the other commissioners. The city employees are under civil service control. The fire department has been completely motorized. The police and fire departments are removed, by law, from political control, and are effectively administered. The water supply of the city was municipalized in 1859, and is conducted with satisfaction to the inhabitants of Trenton. The consumption of water averages about 80 gallons per capita, and the reservoir capacity is 120,000,000 gallons. The board of health has taken an advanced position upon all questions of public sanitation, while the parks of the city, the main breathing ground being named Cadwalader, occupy about 150 acres. An effective system of sewer-drains and paved streets is being extended to all parts of the city, while macadamized roads lead to all nearby rural communities. A bronze statue of Washington, on a granite shaft, marks the place where Washington placed the cannon at the battle of Trenton. A monument to Gen. George B. McClellan is in Riverview Cemetery.

History.— The site of the southeastern portion of Trenton was occupied, as claimed by an influential body of scientists, as the home of man in the Ice Age. (See NEW JERSEY). Near the banks of the Delaware River, during the period of recorded history, was a village of the Unami sub-tribe of the Lenni Lenapé (Delaware) Indians. The name of the princi-

pal creek, Assanpink, running through the city, is a corrupted form of an Indian name meaning "place of stone implements." Many such objects are found in and near the city. The location was known to the Dutch and Swedish peltry traders, who before 1664 came to Trenton to exchange commodities with the Indians. The advent of the members of the Society of Friends at Burlington (1677) led to the development of the nearby territory. These settlers had abandoned the idea of earlier adventurers that precious metals were to be found along the Delaware, that the river was a northwest passage to China, and industriously began the work of colonization, based upon cultivation of land, and the stimulation of river commerce. As early as 1679, certain Englishmen petitioned for lands at "Ye ffalles of ye De La War," by which name the jagged rocks and accompanying rapids were known to the white men. Shortly afterward an unsuccessful settlement was attempted, the actual foundations of the city being laid, when by 1685, Mahlon Stacy built his mill near the junction of the Assanpink Creek and the Delaware River. The history of Trenton during colonial times was uneventful. Certain characteristics are notable. About 1720 the community became known as Trent's town, or Trenton, in honor of a local wealthy Scottish plantation owner, William Trent, Chief Justice of His Majesty's Supreme Court of Judicature for the Colony of New Jersey. The village was the point of contact between the East Jersey (Calvinistic) and West Jersey (Quaker) influences, so conspicuous in the early history of New Jersey, and which have left permanent impress. Located at the head of tide water, and upon one of the great highways between Philadelphia and New York, the community was closely in touch with both cities. As the shiretown of Hunterdon County, erected in 1714–15 from Burlington County, Trenton drew to itself much of the trade of the Upper Delaware as far as "The Forks," now Easton. This trade was conducted by means of canoes and "Durham boats," the latter large scows, drawing little water, built to convey grain and iron ore from the upper river to Philadelphia. In 1745, Trenton became a borough, under royal grant, her charter being surrendered in 1750. Thereafter, the village remained a part of a township of the same name until the opening of the constitutional period. In 1758 and 1759 "barracks," standing in part and patriotically preserved, were erected for the housing of the Crown's regular and provincial troops — a step made necessary by reason of Indian outbreaks in the upper Delaware, during the French and Indian War.

The outbreak of the Revolution found sentiment in Trenton divided. Broadly, the Presbyterians were favorable to war, the Society of Friends were non-combatant, while the members of the Church of England leaned toward support of royal government. A "committee," in the village of about 600 inhabitants, was active in establishing communication between the Whigs of New York and Philadelphia, and as early as 23 May 1775 a Provincial Congress of New Jersey met in Trenton, a principal motive for assembling being the providing for militia regulation in the colony. It was near Trenton that General Washington, en route to take command of the army, upon 23 June 1775, first heard the news of the battle of Bunker Hill. Thence, until Trenton became famous as the spot where was fought one of the great, if not the greatest battle of the Revolution, the village life was without particular incident.

It was upon 8 Dec. 1776, after his memorable "retreat through the Jerseys," that General Washington succeeded in conveying his little army across the Delaware at Trenton, and occupied a ferry-town, later known as Morrisville, named in honor of Robert Morris, the financier of the American Revolution. During the flight of Washington from Fort Lee to Morrisville, it was that Thomas Paine wrote the memorable words, "These are the times that try men's souls," words that later brought the then unexpected response from Lord Germain, colonial secretary of state, "All our hopes were blasted by that unhappy affair at Trenton." The fate of a nation hung in the balance. The Anglo-Hessian troops were in control of New York and quartered at Amboy and New Brunswick, and were raiding for supplies throughout East Jersey. Rall, the Hessian commander, occupied Trenton, with outposts stretched for 20 miles north and south of the city. Philadelphia was threatened, and the Whigs in that city were almost panic-stricken. Washington wrote, "No man, I believe, ever had a greater choice of difficulties and less means to extricate himself from them." Congress, charging Washington with dictatorial powers, fled from Philadelphia to Baltimore, while Eastern Pennsylvania and much of New Jersey were overrun with Tory sympathizers and a riff-raff ready to follow the flag that was in the ascendency. Disappointed in not meeting General Lee, and chagrined at his capture, Washington disposed his force of 10,000 men along the west bank of the Delaware. Four brigades, under Generals Stirling, Mercer, Stephen and DeFennoy held the river fords from New Hope to Yardley; General Ewing occupied Morrisville, opposite Trenton, and Colonel Cadwalader held Bristol, 10 miles below. Taking advantage of the fact that the Hessians would celebrate Christmas with feasting and drinking, Washington prepared to rid West Jersey and Philadelphia of all danger from Anglo-Hessian occupancy. Cadwalader was to cross at Bristol and drive the king's troops from Burlington County, Ewing was to take position south of Trenton, holding Rall's men in check, while Washington was to cross the river nine miles above Trenton, and by a sudden descent capture or destroy the Hessian garrison in the village. Only one part of the plan was made effective. With 2,400 men and 18 pieces of artillery, Washington crossed the river, in a northeast storm, upon the early morning of December 26. Advancing quietly along the road from a point now known as Washington's Crossing, then called McConkey's Ferry, General Washington led his men through sleet and snow and over frozen ground to a point where the highway forked. The army separated about four miles from the village, one division being commanded by Washington, the other by General Sullivan. Both divisions reached Trenton shortly after sunrise. Immediately confusion seized the Rall, Von Lossburg and Von Knyp-

hausen regiments there quartered. Their pickets were driven back, and the battery of Capt. Alexander Hamilton, stationed near the present Battle Monument, swept one of the three principal streets of the town. Rall was wounded unto death, and finding themselves caught in a cul-de-sac, the regimental commanders surrendered at various points in the village. No American officer or enlisted man was killed, and only four were wounded. The Anglo-Hessian loss was about 20 killed and 75 wounded. Nine hundred and eighteen men were captured by Washington, who, during the same day, recrossed the river, with 1,000 of his own men reported unfit for duty. While the battle of Trenton was being fought, neither Ewing at Morrisville nor Cadwalader at Bristol was able to co-operate with Washington, owing to the river being filled with ice floes.

Two causes may be said to have operated to secure the defeat of Colonel Rall. One was the ill-feeling undoubtedly existing between the Hessians and the English, and the consequent lack of discipline. Rall, who had early been warned of Washington's preparations, was drunk upon the night previous to the battle and neglected all customary preparations to meet a foe for whom he had contempt. Washington immediately took advantage of the electrical effect that the battle produced. He recrossed the river from Pennsylvania and upon 2 Jan. 1777 occupied Trenton, with strong outposts established nearby at the villages of Bordentown and Crosswicks. The British generals, Cornwallis and Grant, with 8,000 Anglo-Hessian troops, advanced toward Trenton from New Brunswick, 30 miles distant, fighting their way inch by inch. Through the centre of Trenton passes the Assanpink Creek, then well wooded and surrounded by marshy soil. Washington crossed to the south side of the stream, occupied rising ground, leaving the main part of Trenton to the king's troops. Determining to capture the British stores at New Brunswick, strike a blow at Colonel Charles Mawhood's regiments at Princeton, and in a month regain partial control of "the Jerseys," over which he had been pursued, Washington escaped from Trenton at midnight 3 January. Leaving his camp fires brightly burning, he marched to the eastward of Trenton and early in the morning fell upon Mawhood at Princeton, defeated him, and made away for winter quarters at Morristown. At the battle of Princeton, Gen. Hugh Mercer, for whom Mercer County is named, was brutally stabbed and soon died. During the remainder of the Revolution Trenton was an important centre. To the village were brought spoils captured by the Whigs, and during the British retreat from Philadelphia to Monmouth an attempt was made to divert a body of Anglo-Hessian troops for the purpose of raiding the town. Here met the Committee of Congress that attempted to dispose of the question of the Pennsylvania-Connecticut land grants, which at the close of the Revolution so seriously affected the rights of the settlers in the Wyoming Valley. In 1782, 153 inhabitants of Trenton formed an association to prevent the importation of British goods, and bring all sellers and purchasers to a realization of the dominant Whig spirit. This action was taken to meet a trade-policy begun by British merchants, when it was found that for the purpose of conquering the United States the war was a failure. In June 1783 the Congress of the Confederation, torn by internal dissensions and State prejudices, a wandering body, abused, threatened and insulted, undertook the establishment of a Federal capital, requesting various States to yield to the United States jurisdiction over any district to the extent of 20 miles square and to grant £30,000 in specie for purchase of lands and erection of Federal buildings. Trenton being suggested as a suitable location, a contest between the South and New England was precipitated. A compromise was effected to the end that Congress should meet alternately in Trenton and Annapolis, a plan described by Francis Hopkinson as a new mechanism in government, of a pendulum-like character. Congress met in Annapolis, and a patriotic Trentonian who died in December 1783, made a bequest of £100 to Congress if that body would settle itself at Lamberton, now the southern part of the city. On 1 Nov. 1784 Congress met in Trenton, and an ordinance was passed to lay out a Federal city upon either bank of the river and to provide suitable buildings at a cost of not over $100,000. Congress adjourned to New York, where it met 11 Jan. 1785. Ultimately in the autumn of 1785 the South defeated the appropriation measure, and thus died the plan to make Trenton the capital of the United States.

Before the close of the 18th century, Trenton accorded a reception to President Washington upon 21 April 1789, while he was on his way to New York to attend his, the first, inauguration. A triumphal arch was erected over the Assanpink bridge, while maids and matrons strewed his way with flowers. The Federal government was conducted at Trenton during a smallpox epidemic in Philadelphia immediately before the removal of the public offices to Washington. Upon 25 Nov. 1790, Trenton, after a long contest between East and West Jersey, was chosen, as a compromise, to be the capital of the State, and two years later received a charter as a city, with only minor officers authorized to be selected by a limited electorate. This class legislation, characteristic of the conservative spirit of early State legislation, lasted until the adoption of a State constitution in 1844.

The year 1804 was notable in the history of Trenton for the opening of a bridge across the Delaware River, making an all land stage route from Jersey City to Philadelphia, and the chartering of the Trenton Banking Company, which, with a bank at Newark, organized the same year, were the first in the State. By 1830 Trenton contained about 5,000 inhabitants. With agitation concerning the development of water power, the improvement of highways, the construction of the Delaware and Raritan Canal, and the building of lines of railway to unite New York and Philadelphia, the city entered upon an industrial life. Within 10 years, Trenton had direct communication by land and water with all of the growing cities of the Atlantic seaboard, and her manufactures commanded national attention. Before 1860, her potteries and her metal industries had become well established, although both traced their origin, by sporadic development, to Revolutionary times. Later came the third of Tren-

ton's great industries, that of the rubber goods manufacture. The later history of Trenton is largely the record of commercial development and of steady growth.

Prospective Growth.— Owing to advantageous location upon the lines of great railway systems, its position at the head of tidal navigation, and the slight resistance offered by geological conditions, Trenton is destined to advance rapidly as an industrial centre. The growth of the city is purely normal, the city itself meeting all reasonable demands made by the congesting tendencies of population. An extensive system of trolley lines, one of which unites Philadelphia and New York, has given Trenton a distinctive impulse. Pop. (1900) 73,307; (1910) 96,815; (1918, est.) 110,000.

Bibliography.— Lathrop, J. M., 'Atlas of the City of Trenton and Borough of Princeton' (Philadelphia 1905); Lee, 'History of Trenton' (Trenton 1895); Raum, J. O., 'History of the City of Trenton' (ib. 1871); Volk, Ernest, 'Archæology of the Delaware Valley' (Cambridge, Mass., 1911).

TRENTON, Tenn., city, county-seat of Gibson County, on the Mobile and Ohio Railroad, about 82 miles northeast of Memphis. It is in a fertile agricultural region in which an excellent quality of cotton is grown. The chief manufacturing establishments are cottonseed-oil mills, cotton compress, a large cotton mill, box factory, flour mills and foundries. The educational institutions are the Peabody High School, Laneview Academy, graded elementary schools and a library. Pop. 2,402.

TRENTON FALLS, a series of six beautiful cascades in West Canada Creek, Oneida County, New York, 15 miles north of Utica. The cascades appear at intervals as the creek passes through a ravine two miles long. The total descent, in the two miles, is 312 feet.

TRENTON STAGE, that interval of geologic time during which the Trenton strata of New York and Canada and the equivalent beds of other regions were laid down. Trenton strata are typically developed in the Mohawk Valley in New York State, the type locality being Trenton Falls on the South Canada Creek near Utica. The beds are typically limestones of a dark color and often argillaceous. They are very fossiliferous, among the common species being *Rafinesquiva alternata, Plectambasites sericea, Dalmanella testudinaria, Prasopora tycopordon, Calymmemrenaria, Trinucleus concentricus, Araphus gigas,* and many others. The formation is well developed in the valley of Lake Champlain and in the Upper Saint Lawrence Valley. In southern and central New York the formation is buried by several thousand feet of later strata. Where thus buried it is sometimes a reservoir of gas and oil. In the Upper Mississippi region it is represented by the Galena limestone. On the Cincinnati anticline it underlies the typical Cincinnati beds. In the Hudson Valley it is in part represented by shales carrying a graptolite fauna with *Dicellograptus, Cocnograptus* and other types. In age the formation is Middle Ordovician. See PALÆOZOIC; ORDOVICIAN; CINCINNATI ANTICLINE, etc.

TREPANG, in zoology, a popular name for several edible tropical holothurians (q.v.), especially *H. edulis* of the Oriental seas. It reaches two feet in length and when dried forms an important article of food in China, called by the French *bêche de mer.* About 35 varieties are enumerated by traders, but only five or six have any real commercial value. To prepare them for the market the viscera are removed, and the animals boiled for about 20 minutes, then soaked in fresh water, and afterward smoked and dried. The curing process occupies about four days, during which the trepang must be kept very dry, for it readily absorbs moisture from the atmosphere. The final product is an uninviting rubber-like substance, which is used to prepare a thick soup, much liked in China and the Philippine Islands. Trepang is largely prepared by the Chinese in Hawaii and California from local holothurians, both for local consumption and for export to China. Consult Simmonds, 'Commercial Products of the Sea,' and similar books.

TREPHINE, trĕ-fēn' or trĕ-fīn, a surgical instrument consisting of a cylindrical or crown saw about one-quarter to one inch in diameter, with a cross handle like that of a gimlet, and a centre-pin which, when the instrument is used, is thrust forward a little beyond the level of the teeth of the saw so as to secure accurate implantation and prevent sliding. It resembles in some respects the trepan, and both are used to remove a circular disc or button of bone from the skull. This operation is known as trephining or trepanning, and is resorted to for the purpose of relieving the brain from pressure or irritation. It has been employed in simple fractures with signs of compression; in compound fractures with depression and apparently no compression; in punctured and gunshot fractures, even without symptoms; in coma, from meningeal abscess, hemorrhage and tumors; and in epilepsy and insanity, where lesions could be definitely localized.

TREPORT, Le, a French town situated at the mouth of the Bresle River, 45 miles northeast of Rouen. It is notable for its 16th century tower, the Church of Saint Jacques and an ancient Renaissance house. Its proximity to Paris makes it a popular bathing resort. It has a good harbor and a canal extending to Eu. Pop. about 4,000.

TREPOV, Dmitry Feodorovitch, Russian soldier: b. Saint Petersburg, 1855; d. there, 1906. He entered the army in 1874 and after taking part in the Russo-Turkish War retired in 1896 with the rank of colonel. He was made chief of police of Moscow but was removed in 1905 because of conflicts between the police and students, only to become Governor-General of Saint Petersburg and later Assistant Minister of the Interior with command of the entire police force of the empire. In the latter part of 1905 he became commandant of the Imperial palace where he died.

TRE'R CEIRI, trār chā'rī, the ruins of an ancient British fortified town situated in the northwestern part of Wales, six miles south of Carnarvon. The surrounding fortifications and substantial stone walls of the Cytian-houses or huts are still standing. An investigation in 1903 disclosed a number of Celtic bronze and iron implements and ornaments, specimens of Celtic pottery, and porcelain beads of Egyptian

manufacture, which place the date of the fort at about the 2d century A.D.

TRESCOT, trĕs'kŏt, **William Henry,** American diplomat: b. Charleston, S. C., 10 Nov. 1822; d. Pendleton, S. C., 4 May 1898. He was graduated from the College of Charleston in 1840, studied at Harvard, and was admitted to the bar in 1843. He was secretary to the United States legation at London in 1852–53, assistant secretary of state for South Carolina in 1857–60, resigning upon the secession of that State. In 1862–66 he served in the State legislature and after the close of the war was sent to Washington as the representative of his State during the Reconstruction period. He removed to Washington in 1875 and engaged in law practice there. He was appointed counsel for the United States before the fishery commission at Halifax, Nova Scotia, in 1877, was one of the commissioners to revise the treaty with China in 1880, represented the United States in reference to her rights on the Isthmus of Panama in 1881, and in 1882 was commissioner with General Grant to conclude a commercial treaty with Mexico. He was subsequently engaged in the practice of law at Washington. He published 'A Few Thoughts on the Foreign Policy of the United States' (1849); 'An American View of the Eastern Question' (1854); 'The Diplomatic History of the Administrations of Washington and Adams' (1857), etc.

TRESGUERRAS, Francisco Eduardo, Mexican painter, sculptor and architect: b. at Celaya, 1745; d. 1833. He was educated at San Carlos Academy in Mexico City and was noted as a painter and sculptor in his youth. He designed the Church of Our Lady of Carmen at Celaya, conventual churches at San Miguel de Allenda, a bridge at La Laja and other structures. He was widely known also as a poet and a musician.

TRESHAM, Francis, English courtier: b. about 1567; d. 1605. He was imprisoned for taking part in the Essex rebellion (1601) and was implicated in other plots including Winter's mission to the king of Spain. He died in prison as the result of his intriguing.

TRESPASS is a legal term applied generally to any wrongful entry upon the property of another, and also to mild assaults upon the person, but more especially applied to peaceable, but unlawful entry upon another's property for which there is a remedy by action, for damages. Any person entering the house or grounds of another may be expelled by force, if such is necessary, but trespass is justifiable where the intrusion is for a lawful purpose — as to pay or demand money lawfully due, or to serve any legal process, and forcible entry may be made to execute a criminal process. One who aids and abets the perpetration of a trespass is liable with the one committing same. The straying of one's cattle on another's property has been declared trespass in some jurisdictions. A trespass is deemed wilful when the trespasser has received notice not to intrude, and it is malicious, where the intrusion is designed for the purpose of injury, or annoyance. One in possession of real estate can generally maintain an action against one trespassing against his rights, and such possession can be either in person or by tenant. Trespass may be committed on a highway or road by one who has the use of same against the owner of property adjoining it, and against one who may unlawfully obstruct such highway or road. Any unlawful interference with another's goods or property is trespass, it not being necessary to take actual possession of the same; the taking of one's goods or property by accident, or error, constitutes trespass, unless in the event of some justifiable cause. In many of the jurisdictions there exists by statute, criminal actions for trespass, where the same is wanton or malicious. A trespasser is responsible for the natural consequences of his wrongful or negligent act, but where no special injury is shown, only nominal damages, as a rule, can be recovered. Poaching is a non-legal term applied to trespassing on the property of another for the purposes of killing and stealing game or fish.

TREU, George D. C., German archæologist: b. Saint Petersburg, 1843. Educated at the universities of Dorpat and Berlin, he taught in the latter university (1882) and took part in the excavations at Olympia (1877–81). He published 'Hermes and Praxitiles' (1878); 'Excavations at Olympia' (1879–81); and a number of other works relating to archæological discoveries.

TREVELYAN, trĕ-vĕl'yan, **Sir Charles Edward,** English statesman: b. Taunton, Somerset, 2 April 1807; d. London, 19 June, 1886. He was educated at the Charterhouse and Haileybury College, and entered the East India Company's Bengal civil service in 1826. He returned to England in 1838 and in 1840 was appointed assistant secretary of the treasury. He was knighted in 1848 for his services during the Irish famine, and later, with Sir Stafford Northcote and others, was instrumental in throwing open the civil service to competition. In 1859 he was appointed governor of Madras, but was recalled in 1860 for having protested against a new system of taxation imposed in India. He became Finance Minister in India in 1862, and during his administration introduced various fiscal reforms and also promoted the extension of public works. He resigned because of failing health in 1865, and after his return to England engaged in numerous charitable enterprises. He was created a baronet in 1874. He wrote 'Education of the People of Ireland' (1838); 'The Purchase System in the British Army' (1867); 'Christianity and Hinduism Contrasted' (1882).

TREVELYAN, George Macaulay, English historian: b. 16 Feb. 1876. He was educated at Harrow and at Trinity College, Cambridge; entered the war service (1915–18) and was awarded a medal for valor in Italy. His publications include 'England in the Age of Wycliffe' (1899); 'England under the Stuarts' (1904); 'Garibaldi's Defense of the Roman Republic' (1907); 'Garibaldi and the Making of Italy' (1911); 'The Life of John Bright' (1913), etc.

TREVELYAN, Sir George Otto, English biographer, historian and politician: b. Rothley Temple, Leicestershire, 20 July 1838. He was educated at Harrow and Trinity College, Cambridge, was for several years in the Indian Civil Service, sat in the House of Commons in 1865–68 as the representative of Tynemouth in the

Liberal interest, and in 1868 was returned by the Hawick or Border Burghs. He was appointed a civil lord of the admiralty in Gladstone's administration of 1868, but resigned in 1870 because he disagreed with his colleagues on the Elementary Education Bill. He was prominently identified with the movement for the abolition of the purchase of army commissions, and he was a leading advocate of the electoral reforms effected in 1884–85. In 1880 he accepted the post of parliamentary secretary to the admiralty, and in 1882, after the murder of Lord Frederick Cavendish and Mr. Burke, he went to Ireland as chief secretary to the lord-lieutenant. In 1884 he entered the cabinet as chancellor of the Duchy of Lancaster, and on the formation of Gladstone's short-lived ministry in 1886 he accepted office as secretary of state for Scotland. He resigned less than two months later because he could not support the Home Rule policy of the ministry, and in June of the same year succeeded to the baronetcy. He failed to secure re-election as a Unionist after the dissolution of 1886, but in 1887 he was returned as a Gladstonian Liberal for the Bridgeton division of Glasgow, a constituency which he represented continuously from that date till his retirement from political life early in 1897. In the Liberal government of 1892–95 he was secretary for Scotland. He is favorably known as an author by the following works: 'The Competition Wallah' (1864), a series of letters on Indian matters reprinted from *Macmillan's Magazine;* 'Cawnpore' (1865); 'The Ladies in Parliament, Horace at the University of Athens, and other Pieces' (1868); 'Speeches on Army Reform' (1870); 'The Life and Letters of Lord Macaulay' (1876), an admirable biography of his uncle; 'The Early History of Charles James Fox' (1880); 'The American Revolution' (4 vols., 1909), a strongly panegyrical work, containing many interesting side-lights on the statesmen and soldiers of the period; 'Interludes in Prose and Verse' (1905); 'George III and Charles Fox' (Vol. I, 1912; Vol. II, 1914). See MACAULAY, TREVELYAN'S LIFE OF.

TREVENA, John (ERNEST GEORGE HENHAM), English writer: b. about 1873. He led a wandering life for 20 years on account of ill health but was a prolific writer. Under his own name (Henham) he published 'Menotah: A Tale of the Canadian Northwest' (1897); 'Bonanza: A Story of the Outside' (1901); 'The Plowshare and the Sword' (1903) and others. Under his pseudonym appeared 'Furze the Cruel' (1907); 'The Dartmoor House that Jack Built' (1909); 'Adventures among Wild Flowers' (1914), etc. Consult Cooper, F. T., 'Some English Story Tellers' (New York 1912).

TREVES, trēvz, **Sir Frederick,** English surgeon: b. Dorchester, 15 Feb. 1853. He was educated locally, but developed a talent for surgery, and in 1881–86 was professor of anatomy and pathology in the Royal College of Surgeons. He was examiner in surgery at Cambridge University, and during the Boer War accompanied General Forbes to South Africa as consulting surgeon, and was with the relief column at Ladysmith. He held the post of surgeon extraordinary to Queen Victoria, 1900–01, and performed the operation for appendicitis on King Edward VII, 24 June 1902. He was created a baron during the coronation season. He is the author of works on physical education, surgery and anatomy, and has also published a 'Tale of a Field Hospital' (1900).

TREVES, trēvz (Fr. trâv; Ger. **TRIER,** trēr), Prussia, a town of the Rhine province, situated on the Moselle, six miles from the boundary of Luxemburg and 25 miles northeast of the city of Luxemburg. Outside of southern France no city of Europe north of the Alps contains so many and so well preserved remains from the Roman period as Treves. There are a large amphitheatre built by Trajan, an old Roman gate, the "Black Gate," large and magnificent Roman baths in one of the suburbs, the picturesque ruins of a palace of the Roman emperors, an old church, originally a Roman administrative building, and several other Roman buildings in the surroundings of the city. Portions of the cathedral and the foundations of the bridge across the Moselle are also Roman. The cathedral guards the Holy Mantle, believed to be the shroud in which Christ's body was wrapped. The provincial museum also has a rich collection of antiquities. The municipal library contains over 100,000 volumes. The industries are very varied, the most important being iron foundries, textiles, furniture, tanning, dyeing and joinery. In the neighborhood are lead and copper mines and gypsum quarries. Treves is one of the most ancient towns of central Europe. It was originally the capital of a Gallic tribe called Treviri. During the 4th century it was often the residence of the Roman emperors, and later it became the seat of the powerful archbishops of Treves, who had temporal sway over a considerable territory. In 1794 the territory came under French control, and it was made capital of the department of Sarre. With the fall of Napoleon it passed to Prussia. Pop. of the commune about 47,000.

TREVET, Nicholas. See TRIVET, NICHOLAS.

TREVILIAN RAID and **BATTLE OF TREVILIAN STATION.** On 5 June 1864 General Grant ordered General Sheridan to take two divisions of cavalry and move into Charlottesville, destroy the railroad bridge over the Rivanna near that town, the Central Railroad from that point to Hanover Junction, if practicable, and then rejoin the army. To General Hunter, whom it was expected he would meet at Charlottesville, Sheridan carried instructions to unite with him and join the Army of the Potomac. Sheridan started on the morning of the 7th with Torbert's and Gregg's divisions and four batteries of artillery, in all about 8,000 men. He crossed the Pamunkey at New Castle Ferry, moved up the north bank of the North Anna, marching by way of Aylett's and Chilesburg, crossed both branches of the North Anna on the 10th and at night encamped a little over three miles northeast of Trevilian Station on the Central Railroad. He had heard the day before that General Breckinridge, with an infantry division, was moving up the railroad to Gordonsville and that the Confederate cavalry was marching in the same direction on the south side of the North Anna to intercept his own column, and during the night it was ascertained that it was in his front. General Lee had heard on the morning of the 8th that

Sheridan was on the march, and ordered Gen. Wade Hampton, with his own division of cavalry, to follow in the direction of Gordonsville, directing Gen. Fitzhugh Lee, with another division to follow Hampton as speedily as possible. Hampton had in the two divisions about 5,000 men and three batteries of artillery. On the morning of the 9th Hampton marched from Atlee's Station of the Virginia Central Railroad toward Beaver Dam Station, passed Louisa Court House on the 10th and encamped that night in Green Spring Valley, three miles northwest of Trevilian Station; Fitzhugh Lee near Louisa Court House, about six miles east of the station. During the night Hampton learned where Sheridan had encamped and determined to attack him at Clayton's store, about midway between Trevilian Station and Carpenter's Ford of the North Anna. His own division was to advance by way of the station; Fitzhugh Lee by the direct road from Louisa Court House to the store. Hampton started early, and by daylight had reached the station and was moving on the road to Clayton's store, with Butler's and Young's brigades, Rosser's brigade advancing by a road on his left, when Sheridan was encountered, having scarcely left his camp, Torbert's division in advance and about three miles from the station. There was a sharp skirmish between the advance parties, and Hampton dismounted his men and formed them in dense timber across the road. General Custer, with his brigade, was sent by a wood road on the left to strike the Louisa Court House road and move up in Hampton's rear, passed unnoticed and unopposed to his assigned position, captured many of the Confederate led horses and created much confusion. Sheridan says that as soon as he heard of this the two remaining brigades of Torbert's division were dismounted, assaulted Hampton's position, and carried it, though with severe loss, capturing many prisoners and driving Hampton's men at a run back on Custer at Trevilian Station, some of them through Custer's line, and that Custer began fighting in all directions, capturing many of the enemy. Hampton, however, says he was not driven from position, but that, finding Custer in his rear, he withdrew to a new position, and that Rosser punished Custer severely, driving him back against Fitzhugh Lee, who was coming up, recapturing some ambulances, wagons and three caissons, and taking in addition four caissons and Custer's headquarters wagon. General Gregg attacked Fitzhugh Lee on the Louisa Court House road, drove him and pursued until night. Hampton's division fell back in the direction of Gordonsville and, during the night, was joined by Fitzhugh Lee, who made a detour for that purpose. Sheridan encamped at Trevilian Station. At night Sheridan learned from some of his 500 prisoners that Hunter was moving on Lynchburg and that Breckinridge was at Gordonsville. He, therefore, determined to return, as his ammunition had been much reduced. On the morning of the 12th Gregg's division began the destruction of the railroad toward Louisa Court House and at 3 P.M. Torbert's division, reinforced by a brigade of Gregg's, went up the Gordonsville road to secure a by-road leading over Mallory's Ford of the North Anna, as Sheridan intended to return by way of Spottsylvania Court House. Torbert became heavily engaged with Hampton, the battle continuing until 10 P.M., the advantage remaining with Hampton. During the night Sheridan moved back by the route he had come, recrossing the North Anna at Carpenter's Ford, abandoning some of his very severely wounded, but carrying 377 with him in conveyances of every description, and some 370 prisoners. He reached the White House on the Pamunkey on the 21st, followed by Hampton, who moved on the south side of the North Anna. Sheridan's loss at Trevilian Station on the 11th and 12th was 102 killed, 470 wounded and 435 captured or missing. Hampton says he captured 570 prisoners in the battle and in pursuit, and that the loss in his own division was 59 killed, 258 wounded and 295 missing, a total of 612. The loss in Lee's division is not given. Sheridan marched from White House on the 22d, had a severe engagement with Hampton at Saint Mary's Church (q.v.) on the 24th, and on the 25th and 26th crossed the James River near Bermuda Hundred and rejoined General Grant. His entire loss, June 7–24, was 150 killed, 738 wounded and 624 captured or missing. Consult 'Official Records' (Vol. XXXVI); Humphreys, 'The Virginia Campaign of 1864–65'; Sheridan's 'Personal Memoirs' (Vol. II); The Century Company's 'Battles and Leaders of the Civil War' (Vol. IV).

E. A. CARMAN.

TREVISA, trē-vē'sa, **John,** English writer and translator: b. Cornwall about the middle of the 14th century; d. 1412. He was educated at Queen's College, Oxford, where he was an associate of Wyclif's, and on taking holy orders was appointed vicar of Berkeley, in Gloucestershire, and canon of the collegiate church of Westbury. His chief works are a translation of Higden's 'Polychronicon' (1837), one of the earliest specimens of English prose; of Occam's 'Dialogue between a Soldier and a Clerk,' and of 'Bartholomæus de Proprietatibus Rerum,' which last, a very mine of rare English words, stands in the list of proposed reprints of the Early English Text Society. Caxton said that Trevisa had also translated the Bible; but his version, if it ever existed, is not known to be extant.

TREVISO, Duke of. See MORTIER, EDOUARD ADOLPHE CASIMIR JOSEPH.

TREVISO, trā-vē'sō, Italy, the capital of the province of Treviso in Venetia, situated 16 miles north of Venice. Among its interesting buildings are the cathedral of San Pietro, begun in the 12th century and but recently finished, the large Gothic church of San Nicolò (1310–52), the recently restored provincial palace, a new and fine courthouse and the theatre. There is an academy of sciences, a seminary and technical school and at the Borgo Cavour a notable gallery of paintings and extensive library. The manufactures include hardware, machinery, paper, silk, woolens, chemicals and pottery; and there is a lively trade in grain and cattle. The province is 956 square miles in area and has 550 inhabitants to the mile. Pop. of the town, 43,597; of the province, 524,013.

TREVITHICK, trĕv'ĭ-thik, **Richard,** English engineer and inventor: b. Illogan, Cornwall, 13 April 1771; d. Dartford, Kent, 22 April

1833. In 1797 he succeeded his father as a leading engineer in Cornish mining. Among his first inventions was an improved pump, which soon came into universal use in deep mining. He next perfected a high-pressure steam-engine and began to experiment in the construction of locomotive engines. Passengers were first conveyed by steam by means of his road locomotive in 1801, and he soon after successfully worked a tramroad locomotive. His ideas were later taken up and developed by Stephenson. He was the first to recognize the value of iron in shipbuilding and the application of steam to agriculture. In 1816 he went to Peru, where several engines of his devising were in use in the mines, but the outbreak of the War of Independence 10 years later caused him to lose all his property there. After some adventures in Central America, where he met Robert Stephenson, he returned to England in 1827. His request for recognition and reward for his numerous inventions was disregarded by government, and during his latter years he was in great poverty. Consult the biography by his son Francis (1872).

TREVOR, trē'vor, Sir **John,** English statesman: b. 1626; d. London, 28 May 1672. He entered Parliament in 1646, but attained to no important position until 1659, when he became a member of Monk's council of state. Early in the reign of Charles II, however, he obtained some public employment in France, and in 1668 was again sent there, this time as a special envoy to negotiate a treaty. On his return to England he was knighted and shortly afterward was appointed secretary of state. He was reputed to hold non-conformist opinions, yet his position in the government required him to inquire into and to suppress, where necessary, sectarian meetings in parts of the kingdom. In 1671 he was named on the committee to investigate the petition of Irish landholders dispossessed by Cromwell.

TRIAD. See Harmony.

TRIAD, Hindu. See Trimurti.

TRIAL, Legal (from Old French *trier,* to try, to choose), the examination and determination of the issues between two parties by a judge with a jury, a judge without a jury or by a referee appointed by a court for the purpose, in either civil or criminal proceedings. The trial is that part of a legal action which consists of the court's investigation of the issues in dispute after the arraignment and hearing of the pleas. In a criminal case should the defendant plead guilty there is no trial, sentence being pronounced in the same manner as if the trial had been held and concluded. The trial embraces the opening of the case by the plaintiff's attorney with a concise statement of the cause of action, the examination of witnesses and evidence and the cross-examination of the witnesses by the counsel for the defense, if desired. The defendant's counsel in turn produces his witnesses, who may be cross-examined by the plaintiff's attorney. The defendant's attorney then argues his case and the plaintiff's argument closes the case, and, in civil cases, the trial. In criminal cases the trial includes the judge's charge to the jury and the rendering of the verdict, but does not include the sentence imposed by the judge, nor a hearing on appeal. See Issue; Judgment; Jury; Summary; Verdict.

TRIAL BALANCE. See Bookkeeping.

TRIAL BY BATTLE. See Battle, Trial by; Combat; Ordeal.

TRIANGLE, a figure with three straight sides; a plane figure bounded by three right lines. A spherical triangle is a portion of a spherical surface cut out by three planes which meet at the centre of the sphere and whose sides are each less than a semi-circle of the sphere. It may be equilateral, isosceles, etc. When a plane figure is formed by three arcs of circles intersecting two by two in three angles, it is a circular triangle. An equilateral triangle, having equal sides, is also always equiangular. An isosceles triangle, having two equal sides, has also two equal angles. An oblique triangle is one whose angles are all less than 90 degrees. See Trigonometry.

TRIANGLE, a musical instrument. See Orchestra, The, and Orchestral Instruments.

TRIANGLE. An instrument of hard rubber or similar material used for drawing lines at angles to a "T" square. The two forms commonly in use have right angles and an acute angle of 45°, or of 30°, or 60°.

TRIANGLE OF FORCES. See Mechanics.

TRIANGLE SPIDER. An insect common in the eastern United States, belonging to the *Uloboridæ* and called the *Hyptiotes cavatus.* It makes a web consisting of four radiating lines with a series of double cross lines and from the apex of the triangle a strong line extends to the supporting twig so that by jarring this it loosens the whole net, thus entangling insects in the cross threads.

TRIANGULATION. See Surveying; Geodesy.

TRIANON, Le Grand, le grăñ trē-ă nôñ, Versailles, France, a one-storied palace of considerable extent, formerly a private residence of the French sovereigns, and originally built for Madame de Maintenon by Louis XIV. The palace is visited for its historic interest; its numerous apartments retain much of the original furniture and contain several fine modern works of art. It is called the Grand or Great Trianon to distinguish it from the Petit Trianon.

TRIARTHRUS (triple jointed). An Ordovician trilobite having a depressed carapace of elongated oval outline, the middle third of which is occupied by the broad axis. The best known species is the *Triarthrus becki* of the Utica shales.

TRIASSIC, the oldest period of the Mesozoic era and the system of rocks then formed, so named from its threefold division in Germany, as follows: Transition or Rhætic, Upper Trias or Keuper, Middle Trias or Muschelkalk, Lower Trias or Bunter Sandstein. Of these divisions, the middle one alone is marine, and characterized by marine fossils. The Keuper consists of non-marine sandstones, marls and clays, often with coal seams. The Bunter consists of mottled red and green sandstones, marls and conglomerates with occasional beds

of dolomite, rock salt and gypsum. The typical marine Triassic series of beds is found in the Alps, Himalayas and Siberia. The Triassic is preceded by Carboniferous and followed by Jurassic. In various portions of California and other western States sections are obtained which cover each a greater or smaller interval of the entire Triassic column. Altogether the entire interval is pretty well covered by the various local sections, so that western North America furnishes a nearly complete series of marine Triassic strata. In other regions of North America the Triassic strata are chiefly non-marine. Such is the condition in the interior and such is the character of the Newark system of eastern North America (Nova Scotia, Connecticut Valley, New York, New Jersey and Pennsylvania to Virginia region and the isolated patches in Virginia and the Carolinas). In Europe the Triassic is often called the "New Red" sandstone, in distinction from the "Old Red" sandstone of the Devonian system. This name is little used in the United States.

In portions of the United States the rocks of this period are hardly separable from those of the Jurassic, so that they are frequently known to American paleontologists as "Juratrias." They are represented by various formations along the northern Atlantic Coast; and in this age were erupted the trap overflows whose remains are the Palisades of the Hudson, East and West Rocks, at New Haven, and other similar outcrops in Connecticut. In the interior the terrestrial red beds in the foot-hills of the Rocky Mountains are in part Permian, in part Triassic; and there are extensive marine Juratrias formations on the Pacific Coast, which was the only part of the United States to be extensively submerged during the period. Triassic strata are known over large areas in various parts of the Old World; and in all countries yield some of the best building stones and grits. The famous "Brownstones" of New England and New Jersey are of this age.

The life of the period is not greatly different from that of the Carboniferous, especially in the vegetation, as cycads, tree-ferns, etc., remained prominent. (See PALEOBOTANY). Fishes abounded. Reptiles multiplied on land, particularly the bipedal carnivorous Dinosaurs (terrible reptiles), which reached 40 feet in length, and were the animals that made the so-called "bird-tracks" of the Connecticut Valley. Marine forms also began to develop, such as mosasaurs, plesiosaurs and their relatives in all parts of the world. The most important and characteristic creatures of the time, however, were amphibians, especially of the Stegocephalian type. Compare JURASSIC. See GEOLOGY, and the authorities there cited. Also NEWARK SERIES; NEW RED SANDSTONE.

TRIBE, an aggregation of families of similar descent, united under a common leadership, and forming part of a nation, as in the case of the Roman tribes, or a small nation in itself, as the Sioux or the Cherokee nation of Indians. The tribe was undoubtedly the first step in social organization from the independent family—the human male and female living with their offspring apart from others of their kind, in cave or woods. The tribe was retained in political organizations even of an advanced stage, such as Athens and Rome. It was and is to this day the only form of organization among uncivilized races and it is retained by some of the civilized, such as the Highlanders of Scotland. The tribal system, while in itself a signal advance from the independent family, has generally been found an obstacle to social and political progress when brought into contact and rivalry with higher political development. The progress of Scotland was undoubtedly retarded by the tribal or clan system among the Highlanders and has been wonderfully rapid since the clans were virtually suppressed as political entities by the British government in the 18th century. The internal history of Russia has been largely a struggle of imperial and centralizing against tribal influences. The Indian tribes of America are slowly but surely becoming merged in the general population.

TRIBES, The Lost Ten. See LOST TEN TRIBES, THE.

TRIBUNE, the designation of certain Roman officials, civil and military, with varying rank and power. The title is plainly derived from the tribes which the tribunes represented and the early tribunes were no doubt commanders of the horse and foot furnished to the Roman army by the original tribes. The number of these military tribunes was increased with the number of the tribes; the kings, it is assumed, appointing them while the monarchy lasted, and the consuls succeeding to that power. As the division between patricians and plebeians grew wider the popular assembly became jealous of the consuls and demanded and obtained a voice in the appointment of military tribunes, the tribunes nominated by the popular body ranking as magistrates of the Roman people, as well as military officers. One of the tribunes, known as the *tribunus ærarius,* was the paymaster of the troops.

Far superior to the military tribunes and armed with a power of veto which made them superior even to the consuls, when it came to an issue of authority, were the "tribunes of the commons," created as the result of a long struggle between patricians and plebeians. In 494 B.C. the commons seceded, and took refuge on the Sacred Mount and bound themselves to stand by each other until the patricians should consent to the appointment of two officers to protect the plebeians in their rights. The patricians agreed to the demand and the tribunes of the people, who figured so prominently in the subsequent history of Rome, were created. Their powers increased enormously in the later years of the republic and were ultimately absorbed by the emperors. Consult Botsford, G. W., 'The Roman Assemblies' (New York 1909); Abbott, F. F., 'History and Description of Roman Political Institutions' (Boston 1911). See ROME.

TRIBUNE. An architectural term used to describe that portion of a structure from which an audience is addressed. The term is applied especially to the desk from which a legislator may address the French Chamber of Deputies or the Senate. It is also used to designate the apse of a church or a balcony or gallery for musicians.

TRIBUTE, a sum of money or other property paid by one person or state, at definite

intervals, to another person or state, as acknowledgment of submission or to secure protection or guarantee peace. The custom of giving tribute arose in very early days and was common among the Greeks and Romans. Later it appeared in England and elsewhere under the feudal system, at which time the term was not clearly differentiated from taxes and rent. Sometimes the right to levy tribute is given by treaty between two states. It may be in the form of a contribution raised by a sovereign to defray the expenses of the nation.

TRICERATOPS, a gigantic armored dinosaur found fossil in the Upper Cretaceous rocks of Wyoming. It was larger than a modern rhinoceros and had three great horns, two over the eyes, the other on the proboscis. The skull was phenomenal, a specimen measuring six feet by five, roughly triangular and broad at the rear. The heavy legs ended in three-toed feet. Though frightful of aspect, this great creature, normally 25 feet in length, was a vegetarian, with a most minute brain. See DINOSAURIA.

TRICHECHIDÆ. See PINNIPEDIA.

TRICHIASIS, an inversion of hairs about an orifice of the body, especially of the eyelashes. The inverted lashes irritate the ball of the eye and may cause ulceration and opacity of the cornea. Treatment consists in removal of the offending eyelashes and, when necessary, operative measures to correct the faulty position of the lids. The term trichiasis is also applied to hair-like filaments in the urine, the result of disease of the kidneys or bladder; to a matting and interlacing of hair (*Trichiasis coacta*) and to knotty swellings in the female breasts (*Trichiasis lactea*) from an accumulation and arrest of milk in the milk-ducts.

TRICHINA, a small nematode parasitic in the rat, pig, and man which is the cause of a much dreaded disease termed trichinosis or trichiniasis. The scientific name of the parasite is properly *Trichinella spiralis* and it is believed to have been originally a rat parasite from which host it went over into the hog and from that to man. Two stages are distinguished: (a) Muscle trichina, the immature form, encysted and inactive, and (b) intestinal trichina, the adult form, free and ultimately sexually mature. The species is highly specialized for the parasitic existence and the entire life history is passed within some host. The encysted trichina in muscle tissue if brought living into the stomach of some flesh-eater is set free by the digestion of the cyst. It passes into the intestine and within two and one-half days reaches sexual maturity. After pairing the male dies and the female grows greatly in size. The species is ovo-viviparous, and the first young are produced in about one week from the date of infection. Before giving birth to any, however, the female bores her way into an intestinal villus and lying with the genital pore in a lacteal vessel, pours out all the young into the lymph fluid. They are carried into the musculature and permeate muscle fibres which undergo granular degeneration, while a cyst is formed about each by an infiltration of round cells. Eighteen days are demanded to complete the process, and the young trichina coiled within the cyst is ready for transfer to another host; but it may wait even years before this transfer is effected. Meanwhile there is laid down in and around the cyst calcareous material which gradually encroaches upon and ultimately involves the entire capsule, transforming it to a granule of lime in the muscle. The original discovery of the trichina was made in a dissecting room in London by Dr. Paget who noticed that minute granules in the muscle dulled the edge of the scalpel, and on investigation found the parasite. The cyst may undergo fatty degeneration rather than calcareous. While very resistant against smoking, pickling and even decomposition of the meat, the trichina is readily killed by cooking, so that no danger attaches to the consumption of well-done pork. Prolonged cooking is necessary to bring the centre of large pieces of meat to the proper temperature. Epidemics of trichinosis were very frequent in the last century, especially in Germany where the consumption of smoked but uncooked ham is general. By a system of rigid meat inspection, carried out at large expense, the cases of the disease have been very greatly reduced in Germany. Epidemics have been rare in other countries, though, as will appear later, errors in diagnosis are easy if the disease is not suspected.

Symptoms.— The disease manifests three stages: (a) Intestinal irritation during the growth of the adult trichinæ; (b) myositis with rheumatic pains and fever due to the invasion of the muscles by the larvæ, and (c) period of subsidence corresponding to the encystment of the worms. The severity of the symptoms depends evidently on the individual but primarily on the number of encysted trichinæ that were ingested. Violent symptoms in the first stage have been mistaken for dysentery or cholera, and in the second for rheumatism, while confusion with typhoid is very common. The examination of a fragment of excised muscle will afford positive evidence of trichinæ if present.

HENRY B. WARD,
Professor of Zoology, University of Illinois.

TRICHINIASIS. See TRICHINA.

TRICHINOPOLI, trĭch-ĭn-ŏp'ō-lĭ, or **TRICHINOPOLY,** India, a town in the province of Madras, situated at a railroad junction, on the South Indian Railroad, 190 miles south by west of Madras, on the right bank of the Kaveri River. It is defended by a fortress built on a steep rock, 275 feet high. The rock is crowned by a large pagoda, and another temple carved out of one side of it. It was under native government previous to 1801, when the British acquired control. The town manufactures cutlery, saddlery and jewelry. Pop. 123,512.

TRICHINOSIS. See TRICHINA.

TRICHOME (from a Greek word meaning «growth of hair»), the hair-like outgrowth from the surface of some plants. These may be either uni- or multi-cellular, and if they have flattened expansions at the top are called scales. Glandular hairs secrete various substances which may be either liquid or solid. Root hairs greatly increase the surface for the intake of water and play an important part in this respect. The trichome are used extensively by systematists in describing plants.

TRICHOPTERA. See CADDIS-FLY.

TRICLINIC SYSTEM. See CRYSTALLOGRAPHY.

TRICLINIUM, among the Romans the dining-room where guests were received, furnished with three couches, which occupied three sides of the dinner table, the fourth side being left open for the free ingress and egress of servants. On these couches, which also received the name of triclinium, the guests reclined at dinner or supper. Each couch usually accommodated three persons.

TRICOLOR (French *tricolor*), term applied to a flag having three colors, usually restricted to flags which have the colors in equal masses. See FLAGS OF FOREIGN NATIONS.

TRICOPHYTON. See BARBER'S ITCH; RINGWORM.

TRICYCLE. See BICYCLE.

TRIDENTINE CREED, the profession of the Tridentine faith, published by Pope Pius IV, in 1564. It originally consisted of the Nicene creed, with a summary of the Tridentine definitions, to which is now added a profession of belief in the decrees of the Vatican Council. See TRENT, COUNCIL OF.

TRIDYMITE, a mineral occurring in small, hexagonal tabular crystals in trachyte and other volcanic rocks. Chemically it is pure silica and therefore identical with quartz, from which it differs in its form and lower specific gravity, 2.3. It was first found in Mexico in 1868, but has since been recognized in many localities in Europe, New Zealand, Iceland and the United States. Probably the finest specimens come from Euganean Hills, northern Italy. Its name refers to its frequent occurrence in "three-fold" twin crystals, or trillings.

TRIENNIAL ACT, the name commonly given to the Act of Parliament 16 Charles II, "for the assembling and holding of Parliaments once in three years at least." This act was confirmed after the Revolution of 1688, by 6 William and Mary, cap. ii. The Septennial Act I George I, cap. xxxviii, passed 7 May 1716, empowered Parliaments to sit for seven years. This Act, again, was replaced by the Parliament Act of 1911, which reduced the life of a Parliament to five years.

TRIER. See TREVES.

TRIEST, trē-ĕst' (Italian TRIESTE, the ancient TERGESTEUM), Italy, one of the principal seaports of the kingdom, situated between Görz and Istria in the Coastland, and at the head of the Gulf of Triest, the extreme upper portion of the Adriatic Sea. The city rises from the water in an amphitheatre formed by the sloping escarpment of the Karst plateau. The old town has narrow and crooked streets, but in the newer portions, surrounding it on nearly all sides, the streets are broad and regular, with numerous open squares, ornamented with fountains and monuments. The cathedral of San Giusto stands on an eminence on the site of an old Roman temple. Other notable buildings are the magnificent city hall, the old exchange, the fine building of the Austrian Lloyd, the elegant palace of Revoltella, now a municipal museum, and the large *Teatro Politeama.* There are also remains of a Roman theatre and aqueduct. The principal educational institutions are the commercial and nautical academy, with an observatory, two German and two Italian high schools, a military academy, a public library and archæological museum. The manufactures include soap, candles, confectionery, playing cards and saddlery, and there are breweries, iron foundries, large petroleum refineries, machine shops, oil and lineoleum factories and shipyards. Of the 17 Austrian diets, that of Triest is the sixth in membership. The city is chiefly important for its commerce. During the last decade of the century, however, the progress was not so rapid, owing to keen competition, and to the fact that Triest ceased to be a free port in 1891, after having been so for nearly two centuries. A great extension of the harbor was undertaken about 1905, and completed shortly before the war. There was also much activity in railroad building. Triest has great shipyards and was the headquarters of the great Austrian Lloyd Steamship Company. In 1914 10,686 vessels of 3,871,346 tons were entered and 14,186 vessels of 5,475,445 tons cleared from this port. The principal articles of export are sugar, wool and woolen goods, paper, timber and coal, clothing, metal ware, instruments and watches and glassware. The chief imports are cotton, coffee, fruits and vegetables, hides and animal products, oil, flax and tobacco. Pop. of the city 170,000; of the province about 246,500. About 75 per cent of the people are Italians. It was under Austrian control from 1388 until the end of the World War in 1918, when it passed to Italy.

TRIFOLIUM. See CLOVER.

TRIFORIUM, *in Gothic architecture,* a gallery or arcade with a triple-arched front, above the arches of the nave and below the clearstory. While the triforium was named from its three arches, similar galleries were built and carried the name improperly, having two or four arches.

TRIGGER-FISH, one of the fishes of the plectognath family, *Balistidæ,* in which when the dorsal fin is erected the first ray, which is very thick and strong, holds its elevated position so firmly that it cannot be pressed down; but if the second ray be depressed the first immediately falls down like the hammer of a gun when the trigger is pulled. The 8 or 10 genera and about 100 species are all inhabitants of warm seas. A single species (*B. carolinensis*) of the typical genus *Balistes* occasionally wanders northward on the Atlantic Coast as far as Cape Cod. It is a rather handsome fish, with the body enclosed in a heavy armor of scales and has three stout dorsal spines. The fool-fishes or file-fishes (q.v.), so called on account of their large, expressionless, staring eyes and rough prickly skins, are closely related. In West Indian waters are many representatives of these and other genera and especially of Balistes.

TRIGGS, Oscar Lovell, American educator: b. Greenwood, Ill., 2 Oct. 1865. He was graduated from the University of Minnesota in 1889, studied at the universities of Oxford and Berlin in 1890 and was teacher of English in the University of Chicago 1892-1903. He was editor of Lydgate's 'Assembly of Gods' (1895); coeditor of 'Complete Works of Walt

Whitman' (10 vols., 1902), etc., and has written 'Browning and Whitman; a Study in Democracy' (1893); 'Chapters in the History of the Arts and Crafts Movement' (1903), etc.

TRIGLIDÆ, a family of *acanthopterygian* fishes, deriving its name from *Trigla,* its typical genus, and related to the *Cottidæ.* This family is noted for having cheeks covered with bony plates and the head armed with spines and for membranous appendages; the eyes are set high in the head; one of the suborbitals is very large; the jaw is protracted; there are two dorsal fins, the rays of the first spinous; the first rays of the other fins, except the caudal, are often of the same structure, while all the fins are greatly developed. The family may be divided into six sub-families: (1) *Genus Dactyloptera,* in the species of which genus the pectoral fins are of sufficient length to enable the fish to support itself in the air for a short time. There are two species, *D. volitans* and *D. orientalis;* (2) *Genus Trigla,* typified by *T. cuculus, T. hirundo, T. lyra, T. gurnadus,* the American species, *Prinotus Carolinus, P. tribulus, P. punctatus,* etc.; (3) *Genus Cottuso* including *C. gobio, C. scorpius, C. bubalis, C. quadricornis, C. Virginianus, C. ænus, C. Mitchillii,* etc.; (4) *Genus Aspidophorus,* to which belongs the armed bull-head, *A. Europæus,* noted for being completely covered with horny scales; (5) *Genus Sebastes,* the spines of its main specie, *S. Norvegicus,* being used in Greenland for needles; (6) *Genus Gasterosteus,* which includes the *Sticklebacks,* the most prominent of which are *G. trachurus, G. spinachia, G. biaculeatus, G. neoboracencis, G. quadracus* and *G. occidentalis.*

TRIGLYPH, *in architecture,* ornaments repeated at equal intervals in the Doric frieze. Each triglyph consists of two entire gutters or channels cut to a right angle, called glyphs, and separated by their interstices, called femora, from each other, as well as from two other half-channels that are formed at the sides.

TRIGONIA (from a Greek word meaning "triangular"), is one of the most important types of the lamellibranchs in the Mesozoic seas. The trizoma became most abundant in the middle and upper Jura and the middle Cretaceous but has declined until it now is represented by but five species living in Australian waters. Consult Lycett, John, 'A Monograph of the British Fossil Trigonias' (London 1872–79).

TRIGONOMETRY, invented to meet the needs of astronomy, was for centuries (see TRIGONOMETRY, HISTORY OF THE ELEMENTS OF) but a useful art. At length it was advanced, chiefly by the Swiss mathematician, Leonard Euler, to the dignity of a science. At present, as both an art and a science, it has most intimate connections with nearly every branch of mathematics pure and applied. The aim of this article is to give briefly an intelligible account of the subject with some regard to both its practical and its theoretic aspects.

PLANE TRIGONOMETRY.

Conventions and Definitions.— Any two perpendicular lines, as $X'OX$ and YOY', divide the unbounded plane into four congruent portions, called *quadrants,* which hang together about the *origin* O and of which XOY. YOX', $X'OY'$ and $Y'OX$, taken in order, are known respectively as the 1st, 2d, 3d and 4th.

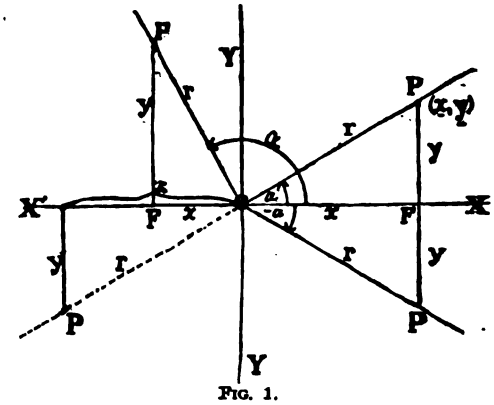

FIG. 1.

The *amount of turning* (about O and in the plane) of a half-line, as OX, which will bring it to coincide with another half-line, as OP, is called the *angle* between them. The angle is regarded *positive* or *negative* according as the turning is counter-clockwise or clockwise. If a half-line turn quite round, so as to coincide with its initial position, it is said to turn through or to generate a *whole,* or round, angle, or perigon. The *unit*-angle used in practical computation is the 360th part of the whole angle, and is named *degree.* The *unit*-angle employed in theoretic investigation is the angle generated by the turning of a half-line, as OP, till one of its points, as P, describes a circle arc equal in length to the segment OP. This unit-angle is named *radian,* being subtended by an arc equal to its radius. Either unit is readily expressible in terms of the other. Thus the whole angle, or 360°, being equal to 2π radians, where π is the ratio of the circumference to the diameter of a circle (see GEOMETRY, ELEMENTARY; GEOMETRY, PURE PROJECTIVE), it is seen that 1 radian = 57.3° (approximately), π radians = 180°, $\frac{\pi}{2} = 90°$, $\frac{\pi}{4} = 45°$, etc. From the definition of angle, it is clear that an angle may exceed 2π. Suppose, for example, that OX generates an angle α (Fig. 1) and then turns through 2π; it will thus have generated the angle $\alpha + 2\pi$. The half-lines bounding an angle are called its beginning and end. Except when otherwise stated or unmistakably implied, all angles will be thought as beginning at OX, *origin of angles.*

$X'OX$ and YOY' are named co-ordinate axes (see GEOMETRY, CARTESIAN); the former, the axis of *abscissæ,* or X-axis; the latter, the axis of ordinates, or Y-axis. Distances on or parallel to the X-axis are considered *positive* if measured *rightward, negative* if *leftward;* distances on or parallel to the Y-axis are *positive* if measured *upward, negative* if *downward.* Accordingly, to each point in the plane (Fig. 1) corresponds a unique pair of numbers, its abscissa and ordinate, its x and y, and conversely.

Definitions of the Trigonometric Functions.— On OP, making *any* angle α with OX, take *any* point P. Complete the figure as indi-

cated, denoting the lengths, of OF, FP and OP by x, y and r respectively. Plainly the values of x, y and r vary with the position of P on OP, but, and this is important, by the laws of similar triangles, their *ratios* do *not*. These ratios do vary, however, and this, too, is important to note, with the value or size of the angle α. Because of this reciprocal dependence of the ratios on α and of α on the ratios, the latter are called *functions* of α, and conversely. Because of their importance, the ratios, or trigonometric functions of the angle have received names and symbols, as follows:

$$\frac{y}{r} = \text{sine of } \alpha = \sin \alpha,$$

$$\frac{r}{y} = \text{cosecant of } \alpha = \operatorname{cosec} \alpha,$$

$$\frac{x}{r} = \text{cosine of } \alpha = \cos \alpha,$$

$$\frac{r}{x} = \text{secant of } \alpha = \sec \alpha,$$

$$\frac{y}{x} = \text{tangent of } \alpha = \tan \alpha,$$

$$\frac{x}{y} = \text{cotangent of } \alpha = \cot \alpha.$$

These equations serve to define sin α and cos α for *all* finite values of α. For any one of the other functions the denominator of the defining ratio becomes zero for certain values of α. Division by zero, being meaningless, is inadmissible. For such values of α, therefore, these functions are not defined. Thus, e.g., the tan is not defined for $\alpha = 90°$. It is indeed customary to write $\tan 90° = \infty$, but this is merely short for saying that, as α approaches 90°, tan α increases beyond every assignable (finite) value.

Range of Variation and Periodicity.— It is readily seen that, if α (Fig. 1) increase or decrease by 2π, then x, y and r regain their initial values. Hence $\sin(\alpha + 2n\pi) = \sin \alpha$, n being any positive or negative integer. Similarly for the other functions. Hence the functions are *periodic*, having the period 2π. It is to be noted, however, that an increase or decrease of α by π alone merely reverses x and y in sign, their ratios remaining the same. Accordingly the period of tan and cot is π. The periodicity of the trigonometric functions, it is, that gives them their great value in Analysis. Each function assumes all the values of its range as α varies through the period of the function. As α varies continuously from 0 to 2π, sin α changes continuously, increasing from 0 for $\alpha = 0$ to 1 for $\alpha = \frac{\pi}{2}$, then decreasing to 0 for $\alpha = \pi$, then changing sign and decreasing (algebraically) to -1 for $\alpha = \frac{3\pi}{2}$ then increasing to 0 for $\alpha = 2\pi$. Meanwhile cos α runs continuously through the same circuit of values, though in different order, beginning and ending with 1, and changing sign at $\alpha = \frac{\pi}{2}$ and $\frac{3\pi}{2}$. Hence sin and cos are restricted to the values 1, -1 and intermediate values. Not so the other functions, however. Both tan and cot assume *all* finite real values, and also vary continuously with α except for those angle values for which, as noted, the definitions fail. For any such value, the function is said to be discontinuous. For example, as α increases through 90°, tan α *leaps* from being great at will and positive to being great at will and negative. The sec and the cosec each assumes every finite real value except those between 1 and -1.

Geometric Depiction.— The above indicated courses of variation of the trigonometric functions may be readily represented graphically, namely, by the so-called curves of sine, cosine, tangent, etc. These are found by the familiar method of analytical geometry (see GEOMETRY, CARTESIAN) for plotting the graph of a function of a real variable. A convenient unit of length is chosen to represent the radian, or unit-angle. Angle values are then laid off on the

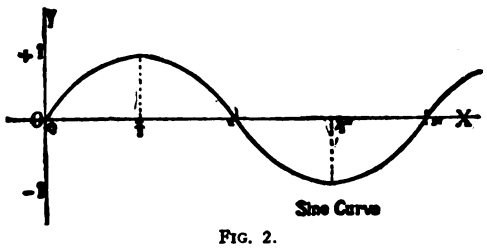

FIG. 2.

X-axis and corresponding function values parallel to the axis of Y. A sufficient number of points being thus determined, a smooth curve, called the graph of the function, is drawn through them. The curve in Fig. 2 is part of the sine curve, or sinusoid. The undulations extend rightward and leftward (for negative angles) indefinitely. The curve of cosines is identical in form with the sinusoid and may be obtained in position from the latter by translating it as a rigid figure leftward through $\frac{\pi}{2}$ units of length. For graphs of the remaining functions, the reader is referred to recent textbooks of trigonometry and analytical geometry. All the graphs in question are *transcendental* curves (see CURVES, HIGHER PLANE; CALCULUS), being intersected by any straight line of the plane in an infinite set of points, real or imaginary.

Functions of Negative Angles.— By reference to Fig. 1 and their definitions, it is immediately seen that the functions of α and the corresponding functions of $-\alpha$ are equal in value but excepting cos and sec, reversed in sign. Thus, symbolically, $\sin \alpha = -\sin(-\alpha)$, $\cos \alpha = \cos(-\alpha)$. Accordingly, cos and sec are called *even*, while the others are called *odd*, functions of the angle, in obvious analogy with the behavior of signs in case of powers of positive and negative quantities.

Complements, Supplements, Explements. —Two angles are called explements, supplements or complements, of each other, according as their sum is 2π, π or $\frac{\pi}{2}$. Any pair of explements are representable by the symbols $\pi + \alpha$ and $\pi - \alpha$; any two supplements by $\frac{\pi}{2} + \alpha$ and $\frac{\pi}{2} - \alpha$; any two complements by $\frac{\pi}{4} + \alpha$ and $\frac{\pi}{4} - \alpha$. The query is natural: how are the values of a function of two explements, or two

supplements, or two complements, related? By reference to Fig. 3, it is plain that $\sin(\pi+\alpha) = -\sin(\pi-\alpha)$ and that $\cos(\pi+\alpha) = \cos(\pi-\alpha)$, since $y=-y'$, $x=x'$ and $r=r'$; hence: *sines of explements are equal in value and opposite in sign; cosines of explements are equal.* In like manner may be detected all the relationships in question, tabulated below:

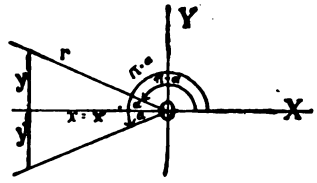

FIG. 3.

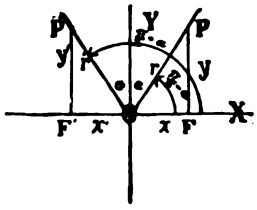

FIG. 4.

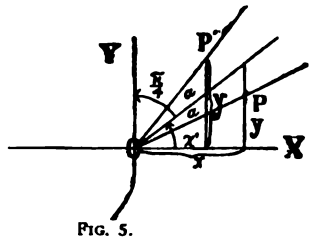

FIG. 5.

Explements, Fig. 3.

$$\begin{aligned}
\sin(\pi+\alpha) &= -\sin(\pi-\alpha),\\
\cos(\pi+\alpha) &= \cos(\pi-\alpha),\\
\tan(\pi+\alpha) &= -\tan(\pi-\alpha),\\
\cot(\pi+\alpha) &= -\cot(\pi-\alpha),\\
\sec(\pi+\alpha) &= \sec(\pi-\alpha),\\
\operatorname{cosec}(\pi+\alpha) &= -\operatorname{cosec}(\pi-\alpha);
\end{aligned}$$

Supplements, Fig. 4.

$$\begin{aligned}
\sin\left(\tfrac{\pi}{2}+\alpha\right) &= \sin\left(\tfrac{\pi}{2}-\alpha\right),\\
\cos\left(\tfrac{\pi}{2}+\alpha\right) &= -\cos\left(\tfrac{\pi}{2}-\alpha\right),\\
\tan\left(\tfrac{\pi}{2}+\alpha\right) &= -\tan\left(\tfrac{\pi}{2}-\alpha\right),\\
\cot\left(\tfrac{\pi}{2}+\alpha\right) &= -\cot\left(\tfrac{\pi}{2}-\alpha\right),\\
\sec\left(\tfrac{\pi}{2}+\alpha\right) &= -\sec\left(\tfrac{\pi}{2}-\alpha\right),\\
\operatorname{cosec}\left(\tfrac{\pi}{2}+\alpha\right) &= \operatorname{cosec}\left(\tfrac{\pi}{2}-\alpha\right);
\end{aligned}$$

Complements, Fig. 5.

$$\begin{aligned}
\sin\left(\tfrac{\pi}{4}+\alpha\right) &= \cos\left(\tfrac{\pi}{4}-\alpha\right),\\
\cos\left(\tfrac{\pi}{4}+\alpha\right) &= \sin\left(\tfrac{\pi}{4}-\alpha\right),\\
\tan\left(\tfrac{\pi}{4}+\alpha\right) &= \cot\left(\tfrac{\pi}{4}-\alpha\right),\\
\cot\left(\tfrac{\pi}{4}+\alpha\right) &= \tan\left(\tfrac{\pi}{4}-\alpha\right),\\
\sec\left(\tfrac{\pi}{4}+\alpha\right) &= \operatorname{cosec}\left(\tfrac{\pi}{4}-\alpha\right),\\
\operatorname{cosec}\left(\tfrac{\pi}{4}+\alpha\right) &= \sec\left(\tfrac{\pi}{4}-\alpha\right).
\end{aligned}$$

Note that in Fig. 4, $r=r'$, $y=y'$, $x=-x'$; that in Fig. 5, $OP=OP'=r=r'$, and that, from the laws of equality among triangles, $x=y'$, $x'=y$. Note, too, that in any of the tables, the sine and cosine relations determine the others, as should be so, since tan and cot are the *ratios*, while cosec and sec are respectively the *reciprocals*, of sin and cos. The mentioned determination is but a special manifestation of the

Interdependence of the Functions.— There is in trigonometry only a single fundamental or characteristic notion, as, say, that of sine — a fact that accounts for the proverbial high degree of plasticity or malleability of the subject matter. Any one of the six functions is derivable from, and expressible in terms of, each of the others. Of such interdependence the definitions themselves of the functions afford illustration. At the same time they furnish the clue to its explicit determination. Thus, squaring and adding corresponding members of the defining equations of sin and cos, and noting that $x^2+y^2=r^2$, one finds the fundamental relation: $\sin^2\alpha + \cos^2\alpha = 1$, whence $\sin\alpha = \pm\sqrt{1-\cos^2\alpha}$, and $\cos\alpha = \pm\sqrt{1-\sin^2\alpha}$; from which, if either $\sin\alpha$ or $\cos\alpha$ be known, the other may be found. In any of the better recent textbooks of trigonometry may be found a readily constructible table expressing each function in terms of each of the remaining ones. The theory of the six trigonometric functions is ultimately the doctrine of a single one of them.

A Table of Critical Values. — Certain critical values of the angle occur so frequently alike in theory and in practice that it seems desirable to tabulate the corresponding function values. The latter may be readily found from the function definitions by help of Fig. 1 and the three accompanying tables. Other angle values of notably frequent occurrence are 30°, or $\frac{\pi}{6}$, and 60°, or $\frac{\pi}{3}$. To find the value of sin 30°, observe, Fig. 1, that, if $\alpha=30°$, y is the half-chord of 60°, i.e., $y=\frac{r}{2}$; whence $\sin 30°=\frac{1}{2}$. From this, by means of the relation, $\cos\alpha=\sqrt{1-\sin^2\alpha}$, it is seen that $\cos 30°=\frac{1}{2}\sqrt{3}$; from this last, since $\cos\left(\frac{\pi}{4}+\alpha\right)\sin=\left(\frac{\pi}{4}-\alpha\right)$, $\sin 60°=\frac{1}{2}\sqrt{3}$; and, similarly, $\sin 30°=\frac{1}{2}$. Thence, by definitions and foregoing formulæ, $\tan 30°=\cot 60°=\frac{1}{\sqrt{3}}$, $\tan 60°=\cot 30°\sqrt{3}$; $\sec 30°=\operatorname{coseco} 60°=\frac{2}{\sqrt{3}}$, $\sec 60°=\operatorname{coseco} 30°=2$. Analogously and by means of relationships to be subsequently given,

$\alpha=$	0	$\frac{\pi}{4}$	$\frac{\pi}{2}$	$\frac{3\pi}{4}$	π	$\frac{5\pi}{4}$	$\frac{3\pi}{2}$	$\frac{7\pi}{4}$	2π	$\frac{9\pi}{4}$
$\sin=$	0	$+\frac{1}{2}\sqrt{2}$	1	$+\frac{1}{2}\sqrt{2}$	0	$-\frac{1}{2}\sqrt{2}$	-1	$-\frac{1}{2}\sqrt{2}$	0

function values corresponding to many other angles, as well as solutions of the inverse problem, admit of explicit determination. Such methods are, however, in general, inconvenient, and, in problems of computation, the determinations in question are, as a rule, effected by means of logarithmic tables. See ALEGBRA, and below.

The Laws of Sine, Cosine and Tangent.— Such may be named the three famous formulæ, now to be presented, that serve for the solution of any triangle, i.e., for the explicit determination of the remaining parts of a triangle of which any three independent parts are known.

By reference to Fig. 6, it is seen that $\sin \alpha = \frac{a}{2r}$;

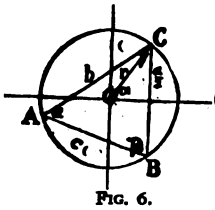

FIG. 6.

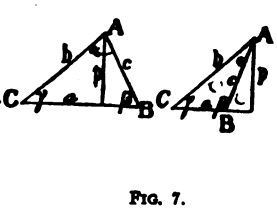

FIG. 7.

similarly, $\sin \beta = \frac{b}{2r}$ and $\sin \gamma = \frac{c}{2r}$; whence, for any triangle of sides a, b, c, and angles α, β, γ, there holds the relation: $\frac{a}{\sin \alpha} = \frac{b}{\sin \beta} = \frac{c}{\sin \gamma} = 2r$, r being the radius of the circumscribed circle. This relation is the LAW OF SINES. It is plain, Fig. 7, that $a = b \cos \gamma + c \cos \beta$, whence $c \cos \beta = a - b \cos \gamma$; squaring, $c^2 \cos^2 \beta = a^2 + b^2 \cos^2 \gamma - 2ab \cos \gamma$; by law of sines, $c \sin \beta = b \sin \gamma$; squaring this, adding to the preceding equations, and noting that $\sin^2 + \cos^2 = 1$, there results $c^2 = a^2 + b^2 - 2ab \cos \gamma$. This and the analogous equations, $b^2 = c^2 + a^2 - 2ca \cos \beta$, $a^2 = b^2 + c^2 - 2bc \cos \alpha$, similarly obtainable, together constitute the LAW OF COSINES. The LAW OF TANGENTS, deduced at a later stage of this article, is, $a + b : a - b = \tan \frac{1}{2}(\alpha + \beta) : \tan \frac{1}{2}(\alpha - \beta)$, where a and b are any two sides of any triangle, and α and β are the opposite corresponding angles.

Addition Theorems.— These serve to express functions of an angle in terms of the like or unlike functions of its parts. Let $OP = OP' = r = r'$ in Fig. 8; α' and α any two angles.

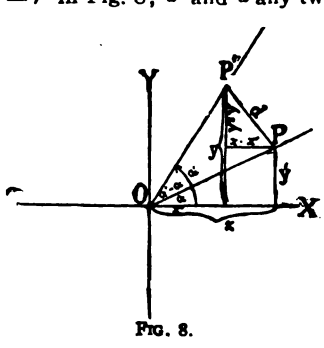

FIG. 8.

It is evident that $x = r \cos \alpha$, $x' = r \cos \alpha'$, $y = r \sin \alpha$, $y' = r \sin \alpha'$. Also, by the Pythagorean theorem and the law of cosines, $d^2 = (x - x')^2 + (y - y')^2 = 2r^2 - 2r^2 \cos (\alpha' - \alpha)$, whence, on substituting $r \cos \alpha$, etc., and reducing, it is sound that $\cos (\alpha' - \alpha) = \cos \alpha' \cos \alpha + \sin \alpha' \sin \alpha$. The four formulæ

(1) $\cos (\alpha - \beta) = \cos \alpha \cos \beta + \sin \alpha \sin \beta$.
(2) $\cos (\alpha + \beta) = \cos \alpha \cos \beta - \sin \alpha \sin \beta$.
(3) $\sin (\alpha + \beta) = \sin \alpha \cos \beta + \cos \alpha \sin \beta$.
(4) $\sin (\alpha - \beta) = \sin \alpha \cos \beta - \cos \alpha \sin \beta$,

are together named the *Addition Theorem for Sine and Cosine*. Formula (1) is equivalent to the preceding one; (2) results from (1) on replacing $-\beta$ for β; (3) from (1) on writing $\frac{\pi}{2} - \alpha$ for α; and (4) from (3), as (2) from (1). Dividing (4) by (1), and both terms of the resulting right-hand quotient by $\cos \alpha \cos \beta$, there results: $\tan (\alpha - \beta) = (\tan \alpha - \tan \beta) : (1 + \tan \alpha \tan \beta)$, which with the relation, $\tan (\alpha + \beta) = (\tan \alpha + \tan \beta) : (1 - \tan \alpha \tan \beta)$, constitutes the *Addition Theorem for the Tangent*. The analogous relations for the remaining functions are omitted as being but little used.

Prosthapheretic Formulæ.— From the addition theorems, which concern functions of *angle* sums and differences, may be easily deduced equally important formulæ concerning *function* sums and differences. Replacing $\alpha + \beta$ by u and $\alpha - \beta$ by v in (1), (2), (3), (4), adding (3) and (4), then (1) and (2), and then adding or subtracting one obtains the four formulæ:

(5) $\sin u + \sin v = 2 \sin \frac{1}{2}(u + v) \cos \frac{1}{2}(u - v)$,
(6) $\cos u + \cos v = 2 \cos \frac{1}{2}(u + v) \cos \frac{1}{2}(u - v)$.
(7) $\sin u - \sin v = 2 \cos \frac{1}{2}(u + v) \sin \frac{1}{2}(u - v)$,
(8) $\cos u - \cos v = -2 \sin \frac{1}{2}(u + v) \sin \frac{1}{2}(u - v)$.

These relations, which have been named *prosthapheretic*,* express sums and differences in terms of products, and so render them suitable for logarithmic computation.

Some Important Deductions from Foregoing Formulæ.—Setting $\alpha - \beta$ in (2) and (3), there result

(9) $\cos 2\alpha = \cos^2 \alpha - \sin^2 \alpha$,
(10) $\sin 2\alpha = 2 \sin \alpha \cos \alpha$.

The former combined with the relation $1 = \sin^2 \alpha + \cos^2 \alpha$ yields

(11) $1 + \cos 2\alpha = 2 \cos^2 \alpha$,
(12) $1 - \cos 2\alpha = 2 \sin^2 \alpha$.

Again, putting $\alpha = \beta$ in addition theorem of tangent, the result is $\tan 2\alpha = 2 \tan \alpha : (1 - \tan^2 \alpha)$. Division of (12) by (11) yields $(1 - \cos 2\alpha) : (1 + \cos 2\alpha) = \tan^2 \alpha$, whence follow

(13) $\cos 2\alpha = \frac{1 - \tan^2 \alpha}{1 + \tan^2 \alpha}$,

(14) $\sin 2\alpha = \frac{2 \tan \alpha}{1 + \tan^2 \alpha}$.

Once more by definition $\tan \alpha = \sin \alpha : \cos \alpha$. Squaring each member and adding 1 to each square, one finds the most used of secant formulæ, $\sec^2 \alpha = 1 + \tan^2 \alpha$. The corresponding cosecant relation is $\operatorname{cosec}^2 \alpha = 1 + \cot^2 \alpha$. Hosts of other more or less useful and interesting kindred formulæ, readily deducible, may be found in the current textbooks and in pocket manuals for engineers. This paragraph will be closed with a deduction of the above presented Law of Tangents. By the Law of Sines, $a : b = \sin \alpha : \sin \beta$; whence, by "composition and division,"

* So called by Prof. W. B. Smith. *Prosthaphæresis* was a method of computation invented by Wittig, a pupil of Tycho Brahe. The method has been superseded by logarithms.

$(a+b):(a-b) = (\sin\alpha + \sin\beta):(\sin\alpha - \sin\beta)$; expanding the right-hand number by (4) and (3), and applying the definition of tangent, the relation sought is found to be $(a+b):(a-b) = \tan\frac{1}{2}(\alpha+\beta):(\tan\frac{1}{2}(\alpha-\beta)$.

Solution of Triangles.— Etymologically trigonometry is *triangle measurement*, and, though the science wonderfully exceeds the verbal significance of its name, yet measurement of triangles is a very important, and, at the same time, the most generally familiar, one of its manifold applications. A triangle is determined by *three independent data*, of which the simplest are: two sides and an angle; two angles and a side; three sides. The three angles are *not independent*, any pair of them determine the third angle. Let a, b, c denote the lengths of the sides, and α, β, γ the corresponding (opposite) angles, of any triangle. The data being those mentioned, three cases arise: (i) given a *pair* of *opposite* parts, and one other, as a, α and b, or a, α and β, to find the remaining parts; (ii) given three *adjacent* parts, as a, γ, and c, or a, c and β, to find the rest; (iii) given three *alternate* parts, a, b and c, to find the angles. In case (i), it is sufficient to employ the Law of Sines; in (ii), the Law of Tangents; in (iii), the Law of Cosines. In (i), if the "one other" part be a side, as b, the Sine Law yields the sine of β, the opposite angle. But, as $\sin\beta = \sin(\pi-\beta)$, the problem presents an ambiguity, which, in every actual example, is readily resoluble by easy considerations explained in every text book of trigonometry. The Cosine Law is equivalent to the equation: $\cos\alpha = (b^2+c^2-a^2):2bc$. The numerator not being a product, the formula is not adapted to logarithmic use. From it, however, is readily derived an adequate formula which is so adapted. It is

$$(15)\quad \tan\tfrac{1}{2}\alpha = \frac{1}{s-a}\sqrt{\frac{(s-a)(s-b)(s-c)}{s}},$$

where s is $\frac{1}{2}(a+b+c)$. Similar relations hold for β and γ. The significance of (15) and its elements is further exhibited by Fig.

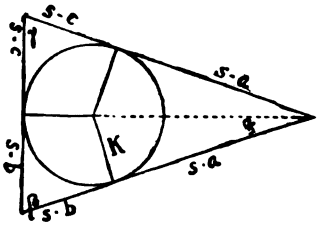

FIG. 9.

9, any triangle and its inscribed circle. The radius K is precisely equal to the radical of (15), whence, if T denote the *area* of the triangle, $T = sK = \sqrt{s(s-a)(s-b)(s-c)}$, a formula attributed to Hero of Alexandria (about 125 B.C.).

Triangle Solution Exemplified.—Given $a = 32.456$, $b = 41.724$, $c = 53.987$; required the angles. Applying logarithms to (15),

$$\log\tan\tfrac{1}{2}\alpha = \log K - \log(s-a).$$

$s = 64.084$, $(s-a) = 31.628$,
$(s-b) = 22.36$, $(s-c) = 10.097$,
$\log(s-a) = 1.50007$, $\log(s-b) = 1.34947$,
$\log(s-c) = 1.00419$, $\operatorname{colog} s = 8.19325 - 10$.

Summing and taking half,

$\log K = 1.02349$; $\log(s-a) = 1.50007$;

whence

$$\log\tan\tfrac{1}{2}\alpha = 9.52342 - 10,$$

whence

$\frac{1}{2}\alpha = 18°\ 27'\ 23''$, $= 36°\ 54'\ 46''$.

In like manner one may find $\beta = 50°\ 32'\ 32''$. and $\gamma = 92°\ 32'\ 44''$. As a *check* one finds $\alpha+\beta+\gamma = 180°\ 0'\ 2''$, an excess regarded in practice as very slight and in most work negligible. To secure more accurate results, which is seldom necessary, it suffices to employ logarithms of more than five decimal places.

Inverse Trigonometric Functions.— The symbols $\arcsin n$ or $\sin^{-1} n$, $\arccos n$ or $\cos^{-1} n$, $\arctan n$ or $\tan^{-1} n$, etc., denote respectively an *angle* whose sine is n, whose cosine is n, etc. They are variously read *inverse* sine, cosine, etc., of n, or *anti-sine*, etc., of n, or, again the *arc* or *angle* whose sine, cosine, etc., is n. They are called *inverse* trigonometric or circular functions, being related to the direct (so-called) trigonometric or circular functions much as are the integral and the derivative of the Calculus (which see), or the logarithm and the exponential of Algebra (which see). Like analogies abound. It should be noted that $\sin^{-1}$, $\cos^{-1}$, etc., do *not* signify reciprocal of sin, cos, etc. Moreover, unless the contrary is expressed, it is generally understood that $\sin^{-1} n$, etc., shall signify the *smallest* positive one of the infinitely many angles whose sine, etc., is n. Thus $\sin^{-1}\frac{1}{2}$ will ordinarily mean 30°, though, taken in full generality, it would signify $30° \pm 2n\pi$, or $150° \pm 2n\pi$, n being any integer. The direct functions are one-valued functions of the angle, but the angle is an infinitely many-valued function of a direct-function value.

Trigonometric Equations.— These are such as involve one or more direct or inverse trigonometric functions regarded as the unknowns or variables like the x, y, etc., of ordinary algebra. Such an equation, for example, is $\sin\alpha + \sin 5\alpha = \sin 3\alpha$. To solve it, apply formula (5); then $2\sin 3\alpha\cos 2\alpha = \sin 3\alpha$; whence either $\sin 3\alpha = 0$, or $2\cos 2\alpha = 1$; hence either $\alpha = n\pi : 3$ or $\alpha = n\pi \pm \pi : 6$. For another example let $\sin^{-1}\frac{3}{5} - \cos^{-1}\frac{12}{13} = \sin^{-1} x$, to find x. Denote $\sin^{-1}\frac{3}{5}$, $\cos^{-1}\frac{12}{13}$, and $\sin^{-1} x$ by α, β, and γ respectively. Then $\sin\alpha = \frac{3}{5}$, $\cos\alpha = \frac{4}{5}$, $\cos\beta = \frac{12}{13}$, $\sin\beta = \frac{5}{13}$, $\sin\gamma = x$. Also $\alpha - \beta = \gamma$, and $\sin(\alpha-\beta) = \sin\alpha\cos\beta - \cos\alpha\sin\beta = \sin\gamma = x$; substituting the values of $\sin\alpha$, etc., it is found that $x = \frac{16}{65}$. For applications to the solution of the general cubic equation in one unknown, the reader is referred to the articles on ALGEBRA or that on EQUATIONS, GENERAL THEORY OF.

Some Trigonometric Series.— Consider the infinite series

$$(s)\quad \sin\alpha = \alpha - \frac{\alpha^3}{1\cdot2\cdot3} + \frac{\alpha^5}{1\cdot2\cdot3\cdot4\cdot5} - \frac{\alpha^7}{1\cdot2\cdot\ldots\cdot7} + \ldots,$$

$$(c)\quad \cos\alpha = 1 - \frac{\alpha^2}{1\cdot2} + \frac{\alpha^4}{1\cdot2\cdot3\cdot4} - \frac{\alpha^6}{1\cdot2\cdot\ldots\cdot8} + \ldots.$$

It may be proved algebraically, and is proved by means of Maclaurin's Expansion (see CALCULUS), that the series (s) and (c) respectively represent or define $\sin\alpha$ and $\cos\alpha$ for every *finite* value of the angle α reckoned in terms of

the radian. The precise meaning is that, if S_n denote the sum of the first n terms of (s), then the *limit* of S_n as n increases endlessly is $\sin a$. Similarly for (c). The algebraic proof is too long for insertion here, and that by the Calculus rests on presuppositions not appropriate in this article. As a compromise it is edifying and interesting to *assume* the validity of equations (s) and (c) and then after the manner of natural science to test them, regarded as hypotheses, by their implications, or consequences. Rigorous proof is not thus obtainable, but certainty can be thus more and more nearly approximated. Any consequence of (s) or (c) or both that is known to be untrue would alone suffice to invalidate one or both assumptions absolutely, while any number of consequences known to be true merely *tend* to support but do not suffice to prove the hypotheses. Some such supporting consequences may be noted. If $a = 0$, series (s) and (c) become respectively 0 and 1, as should be the case, since $\sin 0 = 0$ and $\cos 0 = 1$. If a be replaced by $-a$, each term of (s) is reversed in sign, while (c) is unchanged; and this, too, should be so, for, as before seen, the sin is an *odd*, and the cos an *even*, function of the angle. Again, it is proved in algebra (see ALGEBRA, also SERIES) that, e being the Napierian base.

$$e^a = 1 + a + \frac{a^2}{1\cdot 2} + \frac{a^3}{1\cdot 2\cdot 3} + \ldots \text{ad inf.}$$

for every finite value of a real or imaginary. Writing ia for a, where (after Euler) $i = \sqrt{-1}$, one obtains

$$e^{ia} = \left(1 - \frac{a^2}{1\cdot 2} + \frac{a^4}{1\cdot 2\cdot 3\cdot 4} - \ldots\right) + i\left(a - \frac{a^3}{1\cdot 2\cdot 3} + \frac{a^5}{1\cdot 2\cdot 3\cdot 4\cdot 5} - \ldots\right),$$

or $$e^{ia} = \cos a + i \sin a.$$

Replacing i by $-i$,

$$e^{-ia} = \cos a - i \sin a.$$

The product of the last two equations yields $1 = \cos^2 a + \sin^2 a$, another result known to be true. Once more,

$$e^{i\alpha}\cdot e^{i\beta} = e^{i(\alpha+\beta)} = \cos(\alpha+\beta) + i\sin(\alpha+\beta);$$

also,

$$e^{i\alpha}\cdot e^{i\beta} = (\cos\alpha + i\sin\alpha)(\cos\beta + i\sin\beta)$$
$$= \cos\alpha\cos\beta - \sin\alpha\sin\beta + i(\sin\alpha\cos\beta + \cos\alpha\sin\beta);$$

whence

$$\cos(\alpha+\beta) = \cos\alpha\cos\beta - \sin\alpha\sin\beta,$$

and

$$\sin(\alpha+\beta) = \sin\alpha\cos\beta + \cos\alpha\sin\beta,$$

two equations of the known addition theorem for sine and cosine. It is indeed a fact that the whole body of trigonometric relations deduced or deducible from the original definitions, Fig. 1, of the functions, are obtainable analytically from (s) and (c) regarded as definitions, and, like the latter, would then be free from geometric reference. Each of the other functions, direct or inverse, is representable in the form of a series analogous to (s) and (c). Such series may be found in books of trigonometry and of the calculus.

DeMoivre's Theorem.—From $e^{ia} = \cos\alpha + i\sin\alpha$ it follows that

$$e^{in\alpha} = (\cos\alpha + i\sin\alpha)^n;$$

but $$e^{in\alpha} = \cos n\alpha + i\sin n\alpha,$$

hence $$(\cos\alpha + i\sin\alpha)^n = \cos n\alpha + i\sin n\alpha,$$

a famous theorem due to De Moivre and known as De Moivre's Theorem. Suppose $n = 3$, then

$$\cos 3a + i\sin 3a = (\cos a + i\sin a)^3 = \cos^3 a - 3\cos a\sin^2 a + i(3\cos^2 a\sin a - \sin^3 a);$$

whence $$\cos 3a = \cos^3 a - 3\cos a\sin^2 a,$$
$$\sin 3a = 3\cos^2 a\sin a - \sin^3 a.$$

Similarly sines and cosines of *any multiple* of a may be expressed in terms of the like functions of the single angle.

Euler's Formulæ.— From the relations $e^{ia} = \cos a + i\sin a$, $e^{-ia} = \cos a - i\sin a$, may be found, by addition and subtraction, the Eulerian equations

$$\cos a = \frac{1}{2}(e^{ia} + e^{-ia}), \quad \sin a = \frac{1}{2i}(e^{ia} - e^{-ia}),$$

which are equivalent to (c) and (s) and serve to define sin and cos in terms of imaginary powers of the Napierian base.

Some Curious Relations.— Letting $a = \frac{\pi}{2}$ $e^{ia} = \cos a + i\sin a$, we get $e^{i\pi i} = i$: squaring, we obtain $e^{i\pi} = -1$; also $e^{i^2\pi i} = -i$, and $e^{2\pi i} - 1 = 0$. The last is especially noteworthy as involving the most notable set of five numbers in mathematics: 0, 1, i, e, π. Further developments would lead into the doctrine of Circle Partition (*Kreistheilung*), which belongs to the Theory of Functions of the Complex Variable, to which the reader is referred. See COMPLEX VARIABLE, THEORY OF FUNCTIONS OF A.

SPHERICAL TRIGONOMETRY.

A spherical triangle is the figure bounded by three arcs (of great circles) on the surface of a sphere. Spherical trigonometry has for its principal problem that of determining the numerical values of the three remaining parts of a spherical triangle when three parts are given. This note is confined to triangles whose sides are each less than a semi-circumference and whose angles are each less than π, or 180°. Any spherical angle is measured by the corresponding diedral angle, and the latter by the plane angle of intersecting lines (in the faces of the diedral angle) drawn perpendicular to its edge. For convenience the triangle will be supposed to be on a sphere of *unit* radius; the sides will then be measured by their corresponding central angles. In all mathematics, every problem of angular measurement is ultimately that of measuring the angle between intersecting lines, as all distance problems are reducible to that of determining the distance between two points.

The Right Spherical Triangle.— Let O be the centre of the unit-sphere containing the triangle CAB right-angled at A. BP being drawn

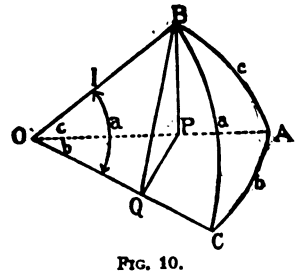

FIG. 10.

perpendicular to OA, and similarly PQ to OC, BQ is perpendicular to OC. By aid of the figure

one may readily find in order the relationships:

(1) $\cos a = \cos b \cos c$, (2) $\sin c = \sin a \sin C$,
(3) $\cos C = \cot a \tan b$ (4) $\sin b = \tan c \cot C$,
(5) $\sin b = \sin a \sin B$, (6) $\cos B = \cot a \tan c$,
(7) $\sin c = \tan b \cot B$, (8) $\cos a = \cot B \cot C$,
(9) $\cos B = \cos b \sin C$, (10) $\cos C = \cos c \sin B$.

Sufficient for the solution of any right triangle, these are less convenient than the equivalent derived set presented under the title

Napier's Circular Parts and Rules.— These parts are: $90° - a$, $90° - B$, $90° - C$, b and c. By substitution in the preceding formulæ, these parts are seen to be related as follows:

(1′) $\sin (90° - a) = \cos b \cos c$,
(2′) $\sin c = \cos (90° - a) \cos (90° - C)$,
(5′) $\sin b = \cos (90° - a) \cos (90° - B)$,
(9′) $\sin (90° - B) = \cos b \cos (90° - C)$,
(10′) $\sin (90° - C) = \cos c \cos (90° - B)$;
(8′) $\sin 90° - a) = \tan (90° - B) \tan (90° - C)$,
(7′) $\sin c = \tan b \tan (90° - B)$,
(4′) $\sin b = \tan c \tan (90° - C)$,
(6′) $\sin (90° - B) = \tan (90° - a) \tan c$,
(3′) $\sin (90° - C) = \tan (90° - a) \tan b$.

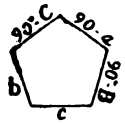

FIG. 11.

Arranging the parts in some such cyclical scheme as in Fig. 11, it will be seen that any part being taken as *middle* part, there are two *adjacent* parts, and two others that may be and are called *opposite*. By inspecting the first half of the preceding table it appears that the sine of any middle part is equal to the product of the cosines of its opposite parts, and, from the second half, that the sine of a middle part is the product of the tangents of its adjacent parts. Such are Napier's rules for circular parts, the more readily remembered by virtue of the assonances appearing in their statement.

In the solution of right spherical triangles it should be observed: (1) that a is less or greater than 90° according as 90° is not or is intermediate to b and c, these being supposed not equal to 90°; (2) b or c and the opposite angle are both less or both greater than 90°; (3) that corresponding to the data, b or c and the opposite angle, there are two solutions.

Quadrantal Triangles.—Those are so named that have a side equal to 90°. The supplemental polar triangle of a quadrantal is right-angled. Hence to solve a quadrantal, solve its polar and subtract its parts each from 180°.

Oblique Spherical Triangles.— The theory

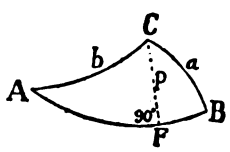

FIG. 12.

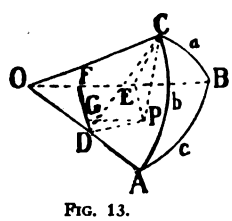

FIG. 13.

of the oblique spherical triangle is contained in the following numbered equations deducible by help of the figures. From Fig. 12 and analogy it is obvious that

(11) $\sin a : \sin b = \sin A : \sin B$,
(12) $\sin b : \sin c = \sin B : \sin C$,
(13) $\sin c : \sin a = \sin C : \sin A$,

three propositions constituting the *Law of Sines* for Spherical Trigonometry. The Law of Cosines, readily found from Fig. 13 (in which CP is perpendicular to the plane AOB, PD, and PE are perpendicular to OA and OB, and PG and DF are parallel to OF and PE), is the triplet:

(14) $\cos a = \cos b \cos c + \sin b \sin c \cos A$,
(15) $\cos b = \cos c \cos a + \sin c \sin a \cos B$,
(16) $\cos c = \cos a \cos b + \sin a \sin b \cos C$.

From these, by passing to the polar triangle (of equal generality with that of Fig. 13), one finds three relations of type

(17) $\cos A = \sin B \sin C \cos a - \cos B \cos C$.

From the law of cosines flow the two triplets of formulæ adapted to logarithmic computation and being respectively of the types

(18) $\tan \frac{1}{2}A = \sqrt{\sin(s-b)\sin(s-a) : \sin s(s-a)}$,

and

(19) $\tan \frac{1}{2}a = \sqrt{-\cos(S-A)\cos S : \cos(S-B)\cos(S-C)}$,

s and S being the *half* sums of the sides and of the angles.

Napier's Analogies.— From (17) by help of the Sine Law are found the so-called *first set* of Napier's analogies, namely

(20) $\cos \frac{1}{2}(a+b) : \cos \frac{1}{2}(a-b) = \cot \frac{1}{2}C : \tan \frac{1}{2}(A+B)$,
(21) $\sin \frac{1}{2}(a+b) : \sin \frac{1}{2}(a-b) = \cot \frac{1}{2}C : \tan \frac{1}{2}(A-B)$;

and from these, by use of the polar triangle, *this second set:*

(22) $\cos \frac{1}{2}(A+B) : \cos \frac{1}{2}(A-B) = \tan \frac{1}{2}c : \tan \frac{1}{2}(a+b)$.
(23) $\sin \frac{1}{2}(A+B) : \sin \frac{1}{2}(A-B) = \tan \frac{1}{2}c : \tan \frac{1}{2}(a+b)$.

For ways of resolving the ambiguity incident to the use of the Sine Law, the reader is referred to any standard work on Spherical Trigonometry. (See *Bibliography*).

Plane Trigonometry a Special Case of Spherical.— The ground of the notable resemblances between corresponding plane and spherical formulæ may be made evident by the following considerations: Suppose a plane p tangent to a sphere of radius r at a point P. If r increase without limit, the one-based zone having P for mid-point will flatten, swelling out toward p so as to include *any* given finite point Q near at will but not on p however far Q be from P. Plane p is said to be the *limit* of the *sphere surface* as r increases limitlessly — a relationship commonly expressed briefly by saying that a plane is a sphere of infinite radius. Accordingly the geometry and the trigonometry on a sphere of radius r ought to degrade respectively into plane geometry and plane trigonometry, on taking r infinitely great. To show that and how, in case of trigonometry, such degeneration actually occurs, consider the spherical Sine Law

(s) $$\frac{\sin a}{\sin \alpha} = \frac{\sin b}{\sin \beta} = \frac{\sin c}{\sin \gamma},$$

where a, b, c are the sides (i.e., the central angles they subtend), and α, β, γ the corresponding angles, of a triangle on a sphere of radius r. Denoting the *lengths* of a, b, c by l, m, n respectively, $a, b, c = \frac{l}{r}, \frac{m}{r}, \frac{n}{r}$ (radian measure). Denoting the *lengths* of a, b, c by l, m, n re-

$$\frac{\sin\frac{l}{r}}{\frac{l}{r}}\cdot\frac{l}{\sin\alpha} = \frac{\sin\frac{m}{r}}{\frac{m}{r}}\cdot\frac{m}{\sin\beta} = \frac{\sin\frac{n}{r}}{\frac{n}{r}}\cdot\frac{n}{\sin\gamma}.$$

Now it may be proved that the *limit of the ratio of the sine to the angle as the angle approaches zero is* 1. Hence as r increases limitlessly and consequently the angles $\frac{l}{r}, \frac{m}{r}, \frac{n}{r}$ (numerators being kept constant, or finite at any rate) approach zero, the foregoing Sine Law degrades into $\frac{l}{\sin\alpha} = \frac{m}{\sin\beta} = \frac{n}{\sin\beta}$, the Sine Law for *plane* triangles. Similarly, by use of the Sine and Cosine Series, it may be shown that the Cosine Law for the sphere degenerates for $r = \infty$ into the Cosine Law for the plane, and that the Tangent Law for the plane is but a special case of the fourth Napierian analogy, the Law of Tangents for the sphere.

Hyperbolic Functions.— These are associated with the rectangular hyperbola (see GEOMETRY, CARTESIAN and CALCULUS) in a manner similar to the connection of the trigonometric or circular functions with the circle. The hyperbolic functions invented by Lambert (1768), may be defined as follows (compare with the Eulerian formulæ): naming them *hyperbolic sine*, etc., and denoting them by *sinh*, etc., their definitions are, $\sinh a = \frac{1}{2}(e^a = e^{-a})$, $\cosh a = \frac{1}{2}(e^a + e^{-a})$, $\tanh a = \sinh a : \cosh a$, etc. Each of the six is expressible in terms of each of the others. Thus $\cosh^2 a - \sinh^2 a = 1$. $\tanh^2 a + \operatorname{sech}^2 a = 1$, etc. These functions are most instructively introduced through the integral calculus. For their geometric interpretation the reader is referred to such works as W. B. Smith's 'Infinitesimal Analysis,' Vol. I, and Greenhill's 'Differential and Integral Calculus.'

Pseudo-spherical Trigonometry.— A given sphere has constant positive *curvature* (see CALCULUS). If the radius be infinite, the curvature is *zero*. The plane is a sphere of constant zero curvature. Suppose the curvature to be constant and *negative*. The surface is then called *pseudo-sphere*. This, too, has its trigonometry. Its formulæ are obtainable from those of spherical trigonometry by replacing the circular functions by the corresponding hyperbolic functions. See TRIGONOMETRY, HISTORY OF THE ELEMENTS OF.

Bibliography.— Chauvenet, 'Treatise on Plane and Spherical Trigonometry' (19th ed., Philadelphia 1881); Loney, 'Plane Trigonometry' (Cambridge 1895); Todhunter, 'Plane Trigonometry' (London 1891); 'Spherical Trigonometry' (London 1901).

CASSIUS J. KEYSER,
Professor of Mathematics, Columbia University.

TRIGONOMETRY, History of the Elements of. Among the ancients trigonometry was simply an adjunct to astronomy, and it so remained until comparatively recent times. A slight trace of its application to mensuration is found in the famous papyrus of Ahmes (see ALGEBRA, HISTORY OF THE ELEMENTS OF), where a quotient called *seqt* is mentioned. In the case of the pyramids the *seqt* seems to have been the cosine of the angle of slope of the edge, or in some cases the tangent of the angle of slope of the face. Among the Greeks frequent reference to trigonometry is found among the writings of the astronomers. Hypsicles (c. 190 B.C.) used the Babylonian division of the circumference into 360 degrees and from this time the sexagesimal fraction became common in astronomy. Hipparchus (c. 150 B.C.) was the first to compute a table of chords, the ancients generally using the chord instead of the half-chord or sine. Hero of Alexandria (see HERO OF ALEXANDRIA) gave rules which are the equivalent of certain modern formulas, and in particular computed the values of $\cot\frac{2\pi}{n}$ for all values of n from 3 to 12 inclusive. Menelaus of Alexandria (c. 100 A.D.) carried the study of Spherics to a considerable prominence, his celebrated *Regula sex quantitatum* relating to the transversal of the sides of a spherical triangle, and he wrote six books on the calculation of chords. It is, however, to Claude Ptolemy (q.v.), c. 125 A.D., that is due the introduction of a formal spherical trigonometry into astronomy. The *Almagest* made the sexagesimal fraction more widely known and Ptolemy calculated the chords of arcs to a half degree.

The Hindu astronomers used the half chord instead of the chord which the Greeks usually (but not always) employed. They thus used the sine, and they added the versed sine and the cosine, computing tables for these ratios. They also knew the relation, $\sin^2 x + \cos^2 x = 1$.

The Arabs made the greatest advance in trigonometry of any peoples before the Renaissance. Al Battani, or Albategnius as the Latin writers called him, c. 900 A.D., brought into greater prominence the use of the sine, and computed a table of values of $\sin x/\cos x$ and its reciprocal, thus practically using the tangent and cotangent. The present names for the various functions are mostly modern. The name *sinus* seems first to have been used by Gherardo of Cremona, c. 1150, although often attributed to Plato of Tivoli (also c. 1150) in his translation of Al Battani. Among the western Arabs, Jabir ibn Aflah, often known as Geber, was prominent, his trigonometry covering both the plane and the spherical parts.

In Christian Europe the science is first seriously considered in the work of Regiomontanus (q.v.), the famous pupil of Peuerbach (q.v). The latter had done some excellent work in trigonometry, but he died before he could write his projected treatise, and Regiomontanus carried out his plans. The result was a work which influenced subsequent textbooks much as Euclid's 'Elements' influenced plane geometry. The principal formulas of plane and spherical trigonometry are set forth and the elementary science became crystallized. Subsequent advances have been chiefly in the nomenclature, the symbolism and the computation of tables, particularly of logarithmic tables. Among the most prominent computers of the values of the functions and of logarithms should be mentioned Rhæticus (1514–76), Pitiscus (1561–

1613), Bürgi (1552–1632), Napier (1550–1617), Briggs (1560–1630) and Vlacq, whose tables appeared in 1628.

DAVID EUGENE SMITH,
Professor of Mathematics, Teachers College, Columbia University, New York.

TRIIODOMETHANE. See IODOFORM.

TRIKALA, tré'kä-lä, or **TRIKKALA,** Greece, city in northwestern Thessaly, 38 miles west of Larissa, with which it has railroad connection by way of the Gulf of Volos. The chief industries are tanning, dyeing and the manufacture of cotton and woolen goods. The ancient town, Trikka, had a famous temple of Æsculapius. Pop. 18,000.

TRIKOUPIS, trē-koo'pĭs, **Charilaos,** Greek statesman, son of Spiridon Trikoupis (q.v.): b. Nauplia, 23 July 1832; d. Cannes, France, 11 April 1896. He inherited his father's literary bent of mind and later began the study of jurisprudence in Athens, afterward studying and completing his course at Paris. His mind then turned toward diplomacy and in 1852 he entered the service of his country as attaché to the legation in London and in 1863 was promoted chargé-d'affaires. In 1865 he was in charge of the negotiations with England which brought about the cession of the Ionian Islands. He was elected to the Boulé the latter part of the same year and joining the Radical party became successively Minister of Foreign Affairs in 1866, Premier in 1875 an again in 1877 Minister of Foreign Affairs in the coalition ministry under Canaris. He then again became Premier in 1878–80 and served also the terms 1882–85, 1886–90, 1891–93 and 1893–95, but at the next election he was defeated and even lost his seat in the Boulé. This was probably due to the low state of the finances of the government, which he had in vain attempted to raise to a degree of stability through the imposition of tariffs and the enactment of agrarian laws as well as by the building of railways. Public confidence in his administrative ability was, however, once more shown by his re-election from the district of Valtos, but he was at the time sick and died before taking his seat. His speeches were published in one volume at Athens in 1888.

TRIKOUPIS, Spiridon, Greek statesman and man of letters: b. Missolonghi, 20 April 1788; d. Athens, 24 Feb. 1873. After completing his education at Paris and London he became private secretary to Lord Guilford at Corfu. In 1821, upon the outbreak of the Greek insurrection, he returned to Missolonghi and joined the patriots. Throughout much of his life he was engaged either in administrative or diplomatic affairs. From 1833–41 he was Minister to England and after 1843 he held in succession the portfolios of the Ministry of Foreign Affairs and of Public Instruction, the Vice-Presidency of the Senate, and the post of Envoy Extraordinary to France. As a man of letters he was among the greatest names of modern Greece. Most celebrated of his works was the oration pronounced on Lord Byron, his friend and associate, at the cathedral of Missolonghi. His 'Poeme des Kliphtes' (1820) is well known, as is also his 'Histoire de la Révolution Grecque' (1853–57).

TRILBY, a novel by George Du Maurier, so named for its principal figure and published in 1894. It is a story of artist life in the Latin Quarter of Paris. It achieved a great and sudden popularity and was very soon dramatized. Trilby, the heroine, is a laundress and artist's model and her relations with three artists, Taffy, the Laird and Little Billee, form the theme.

TRILITHON, or **TRILITH,** a monument, probably sepulchral, either standing alone or forming part of a larger work, and consisting of three stones, two uprights, connected by a continuous impost or architrave. Among the best-known examples of trilithons are those at Stonehenge, on Salisbury Plain, England. In the trilithons still standing, each of the uprights has a tenon on its surface and the under sides of the architrave or horizontal piece have each two mortises into which the tenons fit. Similar monuments are found in Scandinavia over the graves of the distinguished dead.

TRILL, *in music,* the repetition of a note alternately with another, either a half tone or a tone above it. The sign of a trill in music is the syllable *tr* placed over or under the principal note. The trill was known and used at the end of the 16th century.

TRILLIUM, a genus of the family *Liliaceæ,* monocoty-ledonous plants, having all the parts in threes, to which circumstance the generic name refers. They are handsome plants known also as wakerobin, native to North America and Asia. The leaves are triple, in a single whorl, the flower-peduncles arising from the centre. The three petals of the flowers alternate with the same number of sepals. The fruits are large berries, dark red or purple, and sometimes angled. The plants are early blooming smooth perennials, with perpendicular rhizomes ending abruptly and abounding in starch. *Trillium grandiflorum,* which extends from Quebec to Florida and westward, in cool, damp woods, has rhombic, ovate, pointed leaves. The petals are somewhat spreading, pure white or touched with pink, when aged turning to old-rose tints. The painted trillium (*T. undulatum*) is very small, with white petals, narrow and wavy-margined and veined with purple. *T. cernuum* has a white-petal flower nodding on a recurved stalk quite under the leaves, which are broadly rhombic. Other species have green flowers, as *T. viride* and *T. recurvatum,* the latter distinguishable by its reflexed sepals. Two at least are purple-flowered, the blossom of one being sessile (*T. sessile*), and the other (*T. erectum*) having declined flower-stems and reddish purple petals, somewhat acute, and a little longer than the lanceolate sepals. The flowers have a most disagreeable odor, probably attractive to carrion flies, however, and are among the first plants to bloom in the shady, cool woods of eastern America. They are called beth-root or birth-wort, and have a rhizome of sweetish, astringent, acid taste and emetic properties.

TRILOBITE, an early and primitive form of *Crustaceræ* fossil, remains of which are very common in the Paleozoic era. They are doubtless the ancestors of modern *Arachnida,* that is spiders, scorpions and mites. In palæontology, any individual of the order *Trilobita,* so called from the division of the external skeleton into three regions: (1) a cephalic shield; (2) a variable number of body rings and (3) a caudal shield, tail or pygidium. The cephalic shield is usually more or less semicircular, with an elevated portion, the glabella, bounded by the fixed cheeks, to which the free cheeks which bear the eye are attached by the facial suture. The posterior (genal) angles of the free cheek are commonly prolonged into longer or shorter spines. The eyes are sessile, compound and consist of an aggregation of facets, covered by a thin cornea. The number varies greatly, Barrande having found as few as 14 and as many as 15,000 facets in each eye in different types. Behind the cephalic shield comes the thorax, composed of a number of segments (2 to 26), capable of more or less movement on each other; in several genera this freedom of movement was so great that species could roll themselves up into a ball, like a hedgehog. The tail is also composed of a number of segments (from two in *Sao hirsuta* to 28 in the genus *Amphion*), ankylosed or amalgamated. The extremity is sometimes rounded, but may be prolonged into a spine and the ends of the pleuræ of the tail-segments may also be produced into spine-like processes. With regard to the under-surface and appendages of the trilobites much remains to be discovered. The head bears a hypostome or plate in front of the mouth and four pairs of jointed appendages, the basal parts of which were modified to serve as jaws.

From Walcott's examination of sections of rolled-up specimens, it appears that the thoracic appendages were slender, five-jointed legs, in which the terminal segment formed a pointed claw, and the basal segment carried a jointed appendage, homologous with the epipodite of many recent crustaceans. On each side of the thoracic cavity was attached a row of bifid, spiral branchial appendages, and appendages serving also as gills were probably attached to the bases of the thoracic limbs.

Trilobites vary greatly in size, some being scarcely larger than a pin's head, while species of *Asaphus* have been discovered two feet in length. They appear to have lived on muddy bottoms in shallow water, feeding on small marine animals, and probably swam on their backs, as do the recent *Apus* and the larval forms of *Limulus.* The general opinion of zoologists at the present time is that they are related, through the *Xiphosura* and *Limulus,* to the *Arachnida,* and are not crustaceans as formerly believed. Trilobites are characteristic of the Palæozoic system or rocks, and reached their maximum development in the Ordovician. The genera are numerous. (See ARACHNIDA). Consult Zittel and Eastman, 'Text-book of Palæontology'; Walcott, 'Bulletin Museum Comparative Zoology' (Cambridge 1881).

TRILOGY, among the ancient Greeks, a union of three tragedies, connected in subject, which, together with a satirical piece, were performed in immediate succession. There is only one trilogy of antiquity which we can be certain of possessing complete, namely, the 'Orestias' of Æschylus, which contains the 'Agamemnon,' 'Cho phori,' and 'Eumenides.' In modern usage any group of three dramas or operas is so named.

TRIMBLE, trĭm'bl, **Isaac Ridgeway,** American soldier: b. Culpeper County, Va., 15 May 1802; d. Baltimore, Md., 2 Jan. 1888. He was graduated from West Point in 1822, engaged in surveying military roads under the government in 1822–32, and then resigned to pursue the profession of civil engineering. He was afterward engaged as chief engineer on different railroads and at the outbreak of the Civil War joined the Confederate army. He was appointed colonel of engineers in 1861, had charge of the construction of defenses of Norfolk, Va., and later built the batteries at Evansport on the Potomac. He chose the position for the Confederate forces at Cross Keys, 8 June 1862, was engaged at Gaines' Mills, Slaughter Mountain, and at Manassas, and in 1863 was promoted major-general. He took part in the charge of Pickett's division at Gettysburg, where he lost a leg and was taken prisoner. He was exchanged in April 1865 and reached Lynchburg on his way to rejoin Lee, the day after the surrender at Appomattox.

TRIMBLE, Robert, American jurist: b. Berkeley County, Va., 1777; d. 25 Aug. 1828. He removed with his parents to Kentucky in 1831, and there gained with little instruction sufficient education to enable him to teach. He later studied law, was admitted to the bar in 1803 and in that year settled at Paris, Ky., where he engaged in law practice. He was soon afterward chosen to the legislature, was appointed second judge of the Court of Appeals in 1808, and chief justice of Kentucky in 1810. He was United States district attorney in 1813, served as district judge in Kentucky in 1816–26, and from 1826 until his death was a justice of the United States Supreme Court.

TRIMETHYLAMINE (C_3H_9N), an organic chemical compound found in very small quantity in various plants, hawthorn, wild cherry, pear, etc., but contained in considerable amount in herring brine, where it is the result of the decomposition of organic substances containing nitrogen. Obtained usually by the action of heat upon the "vinasses" or residues from the refinery of beet sugar. It can be made in the laboratory by action of methyl iodide upon ammonia. A liquid boiling at 9° to 10° C., soluble in water and possessing a very strong ammoniacal and fishy odor. Its chemical behavior is like ammonia in that its water solution is a strong base which unites with acids to form salts. It may be considered as ammonia NH_3 in which the three hydrogen atoms have been replaced by three methyl (CH_3) groups. The methylamine hydrochloride is used extensively in place of ammonium chloride in the Solvay process for manufacture of potassium carbonate. See CHEMISTRY, PROGRESS OF —*Soda.*

TRIMMER, MRS. Sarah, English writer: b. Ipswich, 1741; d. 1810. She was the author of popular juvenile works, many of which are of an educational character, and her success in founding Sunday schools led to her being summoned to Windsor castle to aid the queen

in similar work. In 1787 she established an industrial school for girls at Brentford which was highly successful. Of her many writings 'Abridgements of the Old and New Testaments' (1793) was given a large circulation by the Society for Promoting Christian Knowledge.

TRIMORPHISM. See ISOMORPHISM.

TRIMŪRTI, trī-moor'tĭ, in the religious system of latter Brahmanism, the Hindu trinity, Brahma, Vishnu and Siva, considered as an inseparable unity. The sectaries of Brahma, Vishnu and Siva respectively make their god the original unity from which the trinity emanates; but considered separately, Brahma is the creating, Vishnu the preserving and Siva the destroying principle of the deity, while Trimūrti is the theological or philosophical unity, which combines these separate forms in one self-existent being. (See BRAHMA; SIVA; VISHNU). The Trimūrti is represented symbolically as one body with three heads, Vishnu at the right, Siva at the left and Brahma in the centre, holding the receptacle for alms and wearing the crown of roses.

TRINCOMALI, trĭng"kō-ma-lē', or **TRIKONAMALAI,** Ceylon, a town situated on Trincomali Bay on the northern part of the east coast. The bay forms a safe harbor of refuge, and is defended by strong fortifications. It has sustained several sieges, and has been held by the Portuguese, by the Dutch twice and by the French three times. It was captured by the British in 1795, and was formally ceded to Great Britain in 1802. Pop. about 11,000.

TRINE, Ralph Waldo, American writer on character building: b. Mount Morris, Ill., 9 Sept. 1866. He was graduated from Knox College, Galesburg, Ill., in 1891, and has published several popular booklets mainly connected with 'New Thought,' including 'What All the World's a-Seeking'; 'In Tune With the Infinite'; 'The Greatest Thing Ever Known' (1898); 'Every Living Creature' (1899); 'The Land of Living Men' (1910); 'The New Alinement of Life' (1913), etc.

TRINE IMMERSION, the name given to the practice in the primitive Church of dipping a person who was being baptized three times beneath the surface of the water, at the naming of the Three Persons of the Holy Trinity. See BAPTISM; BAPTISTS.

TRINIDAD, Colo., city and county-seat of Las Animas County; situated in the extreme southern part of the State, 50 miles east of the Continental Divide, on the Atchison, Topeka and Santa Fé and the Denver and Rio Grande railroads. It was first settled in 1853 by Mexican ranchers; became a town under territorial law in 1872, and a city in 1877. Trinidad is situated in a coal-mining and agricultural region, and derives its business chiefly from mining and trade in agricultural products; there are also railroad shops and a wool-scouring mill, and three banks with a combined capital of $275,000. It contains a Carnegie public library, four public schools, including a high school, a business college, Saint Joseph's Academy and the San Rafael Hospital. The government is vested in a mayor and a board of aldermen of 10 members, elected bi-annually; the waterworks are under municipal ownership. Pop. 14,000.

TRINIDAD, Sp. trē-nē-thäth', Cuba, city, province of Santa Clara, four miles from the southern coast, 40 miles southeast of Cienfuegos. It was founded by Diego Velasquez in 1513. It is connected by railroad with its port, Casilda, and carries on a considerable trade; coffee was formerly its most important export, but the export of sugar is now increasing. It is well situated on high ground, and is one of the most healthful cities on the island. Pop. about 12,000.

TRINIDAD, or **ASCENÃO,** a small uninhabited rocky island in the Atlantic, in lat. 20° 31′ S., long. 29° 20′ W., about 700 miles east of Brazil. Originally discovered by the Portuguese, it had never been claimed or made use of till 1700, when the famous English astronomer, Halley, in the course of a scientific cruise, raised the British flag on the island. No objection was raised by Portugal, to which country, however, the island was transferred in 1782. Since then the island was regarded as a derelict, as no power exercised active possession. In 1880 the English journalist, E. F. Knight, explored the rock and found it littered with dead trunks and branches — the remains of an extinct forest — and swarming with myriads of land crabs, sea-fowl and snakes. There is hardly any fresh water and the island reeked of rotten fish and guano. Access by boat is most difficult, and the water is alive with sharks. The whole area is about five square miles. In 1894 the island had gained a momentary celebrity through the announcement by Baron Harden-Hickey (q.v.), that he had created himself «Prince of Trinidad.» In January 1895, however, the British warship *Barracouta* arrived and landed a party which, climbing up the precipitous rocks, formally read the proclamation of annexation, nailed the British flag on a spar and buried the proclamation in a bottle at the foot. The British government desired to erect a cable station on the island. All the then existing cables between South America and Europe had their western shore-ends at Pernambuco, with the result that Brazil controlled the whole of the direct telegraphic communication of the continent with Europe. The distance between the countries south of Brazil and Europe was too great to admit of a direct cable; hence Trinidad afforded an ideal half-way house. The British annexation roused considerable opposition in Brazil. By mutual consent the dispute was submitted for arbitration to the king of Portugal, who decided in favor of Brazil. Consult Knight, E. F., 'Cruise of the Alert' (London 1890); New York *Tribune,* 11 Feb. 1898.

TRINIL MAN. See MAN, PREHISTORIC RACES OF.

TRINITARIAN, one who believes in the doctrine of the Trinity, the union of three persons, Father, Son and Holy Spirit, in one Godhead. The received doctrine of the Christian Church among Trinitarians holds that it is taught in the Scriptures that there is but one God, and yet that there are three equal subjects in the one Godhead, who are described as persons, but that we cannot determine in what sense these three are separate and in what *sense* they are united in one. The incorporation of

the doctrine of the Trinity in the creeds of Christendom is the result of the attempts to reconcile two seemingly conflicting teachings of the Bible, the first that the Father, Son and Holy Spirit each possess the divine attributes and is worthy to be worshipped, and the second that there is but one God, and that polytheism is sinful.

Under the name Trinitarians, a monastic order (see ORDERS, RELIGIOUS) was founded in the year 1197 by Pope Innocent III for the ransom of Christians captured by the Moors and the Saracens. John de Matha (d. 1213) and Felix de Valois (d. 1212) were the leaders of the order, the former becoming its first general and the latter its first abbot. By 1200 A.D. 200 Christians had been redeemed out of slavery in Morocco by the Trinitarians, and the society spread rapidly in France, Italy and Spain. Aided by Honorius III and Clement IV it afterward spread into Portugal, the United Kingdom, all of south-central Europe and finally to America. From the character of the work done by the order its members came to be known as Redemptionists, and in France by the middle of the 17th century there had been 246 redemptions, releasing 30,720 prisoners, while the numbers for Castile and Leon were 362 redemptions and 11,809 prisoners. By the 18th century the order possessed over 300 houses, but it was rapidly nearing its end, which came in the latter half of that century; it is now almost extinct, having outlived its usefulness.

TRINITROPHENOL. See PICRIC ACID.

TRINITROTOLUENE, or **TNT,** $C_6H_2(CH_3)(NO_2)_3$, a high explosive, the final nitration product of toluene, is obtained by the energetic treatment of this hydrocarbon with strong nitric acid in the presence of concentrated sulphuric acid. The reaction takes place in three stages, with the formation of mononitrotoluene and dinitrotoluene as intermediate products. The compound has also been prepared on a large scale by dissolving orthonitrotoluene in 100 per cent sulphuric acid at 60–70° C.; a mixture of nitric and sulphuric acids is allowed to run into the solution in a fine stream with constant stirring and cooling. Under these conditions the formation of dinitrotoluene is indicated by a drop in temperature. In order to complete the reaction, the mixture is maintained at a temperature of 120–130° C. for one hour. An increase in yield is claimed by the addition of water to the reaction mixture at 100° C. During the process of manufacture a number of inorganic salts are produced by the action of acids on nitrating chambers; these impurities act as catalysers and promote the formation of nitrated cresols and other by-products, which may form unstable salts with metals, causing premature explosions. It is, therefore, necessary to prepare a compound of high purity. For this purpose the crude product is removed from the nitrators as soon as the desired reaction comes to an end, and purified by first washing with boiling water; volatile impurities are removed by keeping the compound at 95–100° C. for several hours; it is then crystallized from a mixture of 90 per cent alcohol and benzene. Patents have also been issued dealing with purification by dissolving in hot concentrated sulphuric acid and extracting the product by dilution and cooling. The compound has further been purified by recrystallization from orthonitrotoluene.

Pure trinitrotoluene crystallizes in almost white needles which melt at 80.6° C., and possess a density of 1.6. Its density may be increased to 1.7 by melting and pouring into shells, or by allowing the molten mass to cool under pressure. It dissolves readily in alcohol, acetone, benzene, toluene, nitrotoluene, and fairly readily in hot concentrated sulphuric acid.

Although trinitrotoluene does not quite possess the detonating power of picric acid, in many respects it is decidedly superior to this competitor. At ordinary temperatures it is a perfectly stable explosive; it may be compressed into shells, mines, torpedoes and into slabs or cylinders with perfect safety, and the pressed charges withstand impact of high power bullets without exploding. The compound is non-hygroscopic, and its dust or vapor are not irritating. Having no acid properties it is inert in the presence of metals or their oxides. When ignited it burns with a smoky flame, and when detonated with mercury fulminate it leaves no poisonous vapors or gases, and having a much lower melting point than picric acid, it may be poured into shells at lower temperatures. On account of these properties trinitrotoluene has been extensively employed, sometimes in preference to picric acid, as an explosive for shells, mines, hand grenades and torpedoes. It has also been used in safety detonators. Being somewhat deficient in oxygen, it is often mixed with potassium chlorate, lead nitrate and other compounds that can supply the necessary oxygen.

Trinitrotoluene exists in six isomeric modifications. These are of practically the same value as explosives. The commercial product usually contains the symmetrical compound (1-methyl 2, 4, 6-trinitrobenzene), although the other isomers may also be present.

V. S. BABASINIAN,
Lehigh University.

TRINITY, (1) a river which has its rise in the Shasta Mountains and flows through Trinity County, in the northeastern part of California. It has two forks and empties into the Klamath River in Humboldt County. Its length is about 250 miles. (2) A river in Texas which has its rise in a group of streams north of Dallas and Fort Worth in the northern part of the State. It flows east and southeast and enters Galveston Bay, an arm of the Gulf of Mexico. The total length is 560 miles. At high water it is navigable for small boats a distance of 500 miles. It flows through a rich agricultural country.

TRINITY BAY, Newfoundland, a large irregular bay on the southeast coast, cutting off, together with Placentia Bay, the peninsula of Avalon from the main part of the island. Its chief port is Heart's Content.

TRINITY COLLEGE, Cambridge, England, founded by Henry VIII in 1546 on the site and out of the revenues of Michael-house (1324), King's Hall (1337), and other ancient societies, is the largest college of the university. To the 60 fellowships and scholarships of the foundation Queen Mary added 20 scholarships. The scholarships, which are tenable up to the M.A. degree, have a yearly value of from $150 to $500, the sizarships of about $350, and there

are further three annual minor scholarships of $350 and three of $250, tenable for three years, besides 16 exhibitions for scholars from Westminster, Saint Paul's, Lynn, Shrewsbury, etc., and numerous prizes. The fellows, with certain exceptions, must take holy orders within seven years after their M.A., and the college may elect professors or other distinguished literary or scientific men to regular or honorary fellowships. Trinity is more conspicuous for the extent than the special architectural beauty of its buildings. Noteworthy, however, are Nevill's Fountain, the three great gateways by which the three chief courts are entered, the Gothic Hall with its high-peaked roof, the chapel (re-decorated 1875), the library designed by Wren and containing 100,000 volumes, the Master's Lodge, with its state-rooms, where royalty and the judges are received, and the rich collection of busts and statues of former members — of Newton by Roubillac, Porson by Chantrey, Byron by Thorwaldsen, Barrow, Macaulay, Whewell, Sedgwick, Tennyson, etc. The gross income in 1917 was £81,472 and the undergraduates numbered 595, with 3,255 members on the boards.

TRINITY COLLEGE, located at Durham, N. C. It was founded as a school of secondary grade in 1838 and was then located in Randolph County; in 1851 it became a normal college and the next year established a full college course and was granted power to confer degrees. In 1857 it was placed under the control of the North Carolina Conference of the Methodist Episcopal Church, South, and in 1859 the name was changed to Trinity College. During the Civil War the college was compelled to close, and was reopened in 1866. In 1891 it was moved to its present site in Durham. Women were admitted to all privileges of the college in 1896. The college offers three groups of studies, all leading to the degree of A. B., the first group requires Latin and Greek in the first two years, the second group substitutes French or German for Greek, and the third group is for students intending to do advanced work in mechanical, electrical or civil engineering; the work of the last three years is partially elective. Provision is also made for graduate work for which the degree of A.M., is conferred. There are 50 scholarships and two loan funds for the aid of poor students; tuition is free for those studying for the ministry. A new charter extending the scope of its activities was granted in 1903. The grounds, consisting of 73½ acres, are known as Trinity College Park, and are under the municipal government of Durham; the buildings include the Washington Duke building, the Crowell Science building, the Epworth building, the Mary Duke building, the Craven Memorial hall, the Angier Duke gymnasium, a dormitory (erected 1902) and the library of 52,000 volumes (completed 1903). The productive funds in 1917 amounted to $1,641,000, the increase being largely due to donations from James B. and N. Duke; the students numbered 705 and the faculty 52.

TRINITY COLLEGE, Hartford, Conn., was founded by Bishop Brownell of the Protestant Episcopal Church in 1823 and was then chartered as Washington College. In 1845 the name was changed to Trinity College; in 1872 the original campus was sold to the city of Hartford as the site for the State Capitol and the college moved to its present site in the suburbs. The college offers (1) a course in arts leading to the degree of A.B.; (2) a course in science, leading to the degree of B.S.; (3) a course in civil engineering, added to the curriculum in 1903–04; those taking this course may receive either the degree of A.B., or B.S., according to their electives; (4) graduate courses leading to the degrees of M.A., and M.S. The college has a large number of scholarships, two fellowships and several graduate scholarships. The principal buildings are of brown stone, secular Gothic in architecture. The library in 1918 contained 85,000 volumes. The productive funds amounted to $1,618,000. The average attendance is about 250 and the faculty numbers 25.

TRINITY COLLEGE, Ireland, is said to have been founded by Queen Elizabeth in 1591. Some authorities, however, assert that she merely endowed and Protestantized the school and that its establishment was due to Alexander Bigner or Bignor, an ecclesiastic of the 13th century. It is the largest and most important educational institution in Ireland and has extensive buildings which enclose several quadrangles. Corinthian columns ornament the principal front, the chapel has a Corinthian portico and the decorations of the fine library are also Corinthian. See DUBLIN, UNIVERSITY OF.

TRINITY COLLEGE, Oxford, England, was founded by Richard de Hoton, prior of Durham, in 1290, for the education of the student monks of Durham. It was rebuilt and improved by Sir Thomas Pope in 1554, and after Balliol was the first college re-endowed by a layman, and further remarkable in view of the Reformation, as being, like Saint John's, indebted for this to a Roman Catholic. The faculty consists of a president, 12 fellows, several honorary fellows and lecturers. There are 21 scholarships, nine exhibitions, and the average annual attendance of undergraduates is about 200. The college has in its gifts 10 church livings. The buildings surround a fine quadrangle and include a Renaissance chapel, built in 1694, in which is a fine altar-piece and a beautiful carved screen. Among the distinguished alumni are Sheldon, Ludlow, Ireton, Newman, Pitt, North, Stubbs, Rawlinson and Bryce. The gross income in 1917 was £10,024 and the undergraduates numbered 158.

TRINITY COLLEGE, a Roman Catholic institution for the higher education of women, located at Washington, D. C. It was founded by the Sisters of Notre Dame (Namur), and was first opened to students in 1900. It offers two college courses leading to the degrees of A.B., and B.L., respectively; and has no preparatory department. The library in 1917 contained over 15,000 volumes; the income amounted to $25,000; there were 10 instructors and the students numbered 281

TRINITY COLLEGE, University of, situated at Toronto, Canada, and federated, since 1903, with the University of Toronto. The University of Trinity College was founded by royal charter in 1852, and up to 1903 conferred degrees in arts, divinity, medicine, law, music, dentistry and pharmacy. At present, under the terms of the federation with the Uni-

versity of Toronto, Trinity University confers degrees, under its own charter, only in the faculty of divinity and co-operates with the University of Toronto in giving instruction in the faculty of arts, the degrees in this faculty and in all other faculties, except divinity, being conferred by the University of Toronto. Trinity Medical College, which prior to the federation was the teaching body in the faculty of medicine, was amalgamated in 1903 with the Toronto Medical College to form the faculty of medicine in the University of Toronto. The arts courses are open to both men and women. The divinity courses are maintained in close connection with the Church of England in Canada and students are prepared for the ministry of that Church. Trinity College has always made residential collegiate life one of its prominent features, the men students residing in Trinity College and the women students residing in Saint Hilda's College, which is open only to women students of the University of Toronto enrolled in Trinity College. See also TORONTO, UNIVERSITY OF.

TRINITY DOCTRINE, the Christian doctrine of the triune nature of God. The doctrine of the Trinity is nowhere expressly taught in the Old Testament. The doctrine in regard to the divine nature which is most strongly insisted on throughout the Old Testament is the unity of God as opposed to polytheism, and by the names by which God revealed himself to Moses (Ex. iii, 14, 15, and other passages) it is implied that the divine nature is inscrutable to human intelligence. The plural form used to designate the Deity in the account of the creation, and many other incidental circumstances or expressions, are, however, held as implying, if not teaching, this doctrine.

In the New Testament it is evident that the doctrine of a Trinity in the divine nature is clearly and copiously taught. In the Gospels Christ himself asserts a mysterious union between himself and the Father, appropriates to himself by an evident allusion the mysterious name of God revealed to Moses, and repeatedly refers to the Holy Spirit along with the Father as partaking of the same divine nature and union. The same doctrine is implied in the teaching of John, the forerunner. In the baptism of Christ by him the Holy Spirit is represented as descending visibly upon him while he is recognized by an audible voice from the Father, and in the rite of baptism instituted by Christ the names of Father, Son and Holy Ghost are used as the joint designation of the divine being. The apostles and other writers of the New Testament Epistles constantly employ this form both in the introductory assertion of their authority and in their closing benedictions.

Among the definitions which resulted from the conflict of opinion in the early Church with regard to the doctrine of the Trinity, that which was adopted by the Catholic Church, and is generally accepted by orthodox Christians, fairly claims the merit of the fullest harmony and most comprehensive consistency with the various statements of Scripture. It is that there are in the Godhead three persons, one in substance, coeternal, equal in power, the Father, Son and Holy Ghost. It was only, however, after a severe and protracted conflict that this definition came to be generally accepted, and as soon as the definition proceeds one step further a wide schism again separates the Church. The Eastern Church holds that the Holy Ghost proceeds from the Father; the Western, throughout all its divisions, adopting the amended form of the Nicene Creed, holds that he proceeds from the Father and the Son. The three creeds commonly called the Apostles', the Athanasian and the Nicene, all contain the points of agreement between the two divisions of the Church, while on the point of difference the Athanasian and the commonly known form of the Nicene express the faith of the Western Church. The word "Trinity" is not in Scripture. The term persons is not applied in Scripture to the Trinity, but something analogous to the conception of personality seems to be implied in the apostolical arguments of the epistles. See ARIANISM; NICÆ, THE COUNCILS OF; NICENE CREED; UNITARIANISM.

TRINITY HALL, an English college at Cambridge, founded in 1350 by William Bateman, bishop of Norwich. It continues to be the legal college of the university under the new statutes in force since 1882 and presents seven livings. Consult Malden, H. E., 'Trinity Hall' (London 1902).

TRINITY HOUSE, Corporation of the. An old English religious corporation dating back to the reign of Henry VIII and managed by a board called the Elder Brethren, selected from the naval and the merchant service. It now controls the more important lighthouses, light-ships and fog signals on the English Coast. Its headquarters are in London and its specific duties are lighting and buoying the Thames and adjacent coast.

TRINITY RIVER, a Texan stream flowing southeast and emptying into Galveston Bay about 40 miles north of the city of Galveston. It is formed from a network of small streams in Montague, Jack, Denton, Parker and Wise counties and frequently runs dry above Dallas. It is over 500 miles long.

TRINITY SUNDAY, so called from being set aside in special honor of the Trinity. It comes directly after Whitsunday and was established as a common festival by decree of John XXII who died 1334.

TRINODA NECESSITAS, a triple tax imposed for public purposes from which no lands, whether used for secular or religious purposes, were exempt in Anglo-Saxon times. These taxes were for the maintenance of bridges and highways, for the erection and keeping in repair of fortresses and for the support of the king's naval and military forces.

TRINUCLEUS (from the Latin *tres,* three, and *nucleus,* little nut). A trilobitic genus of the middle and upper Ordovician rocks. The body seldom exceeds an inch in length and has a broad horseshoe-shaped head shield. The head is bordered by a wide pitted margin; the glabella is convex and consists of a prominent median and two less elevated lateral lobes. In some forms the young were provided with simple eyes. The thorax had six segments with narrow axis.

TRIO, *in music,* a composition for three voices or for three instruments. In a specific sense the term "trio" is used to indicate a middle section in a composition and derived its

name from the three-part writing in this middle section employed by the old composers.

TRIONAL, a harmless hypnotic, best administered in hot milk. It is a white crystalline powder prepared by the action of methyl-ethyl ketone upon mercaptan and the oxidation of the resulting product by permanganate of potassium. It melts at 169° F., and is readily soluble in alcohol, but sparingly so in water.

TRIPALMITIN. See PALMITIN.

TRIPHENYLMETHANE DYESTUFFS. See COAL-TAR COLORS.

TRIPHENYLMETHYL, obviously a derivative of the radicle methyl which cannot exist independently. This remarkable substance was discovered by Gomberg in 1901 and may be prepared by the action of metals on chlorotriphenylmethane. It forms a colorless crystalline solid, melting at 293° F. and acts as a highly-unsaturated compound which when dissolved in liquid sulphur dioxide conducts the electric current.

TRIPHYLITE. See LITHIOPHILITE.

TRIPITAKA. See PITAKA.

TRIPLE ALLIANCE, a name applied to various international agreements, the earliest being that concluded in 1668 between England, Holland and Sweden, with the object of opposing the advance of France. Within two years, however, Charles II of England signed a treaty with the French king, binding himself not to interfere with the French designs on the Netherlands.

(2) An alliance formed in 1717 between England, France and Holland, guaranteeing the clauses of the Treaty of Utrecht referring to the English Protestant succession, the French succession and the renunciation by Spain of her claims to the throne of France. It was intended as a counterpoise to the alliance of Russia, Sweden and Spain, and by the adhesion of Austria became the Quadruple Alliance in 1718.

(3) The Triple Alliance (India) was formed between the English, the Peshwa and the Nizam in 1790 with the object of invading the dominions of Tippoo Sahib and equally sharing them between the contracting parties.

(4) The alliance of Brazil, Argentina and Uruguay in the war waged against Paraguay from 1865 to 1869.

(5) The most important Triple Alliance, and the one usually intended by the term, is that concluded between Austria-Hungary and the German Empire in 1879, to which Italy became a party in May 1882. The text of the treaty of alliance between Austria-Hungary and Germany — which is not subject to periodical renewal — was first made public on 3 Feb. 1888. That between Italy and Austria-Hungary was never made public until 1915, after Italy's denunciation of it on 4 May and declaration of war against her former ally, Austria, on the 23d. The preamble of the treaty between Germany and Austria-Hungary of 1879 declared that a "solid alliance" between the two empires "can threaten no one, but is rather calculated to consolidate European peace as created by the stipulations of the Treaty of Berlin" (of 1878). The two emperors, therefore, solemnly promised each other "never to give an aggressive tendency whatever to their purely defensive agreement."

Article I of the treaty reads as follows:

"If, contrarily to what may be hoped and contrarily to the sincere wishes of the two high contracting parties, one of the two Empires were to be attacked by Russia, the two high contracting parties are bound to lend each other reciprocal aid with the whole of their imperial military power, and, subsequently, to conclude no peace except conjointly and in agreement."

Article II declares that:

"If one of the two high contracting parties were to be attacked by another Power, the other high contracting party binds itself, by the present act, not only not to uphold the aggressor against its high ally, but at the least, to observe a benevolent neutrality with regard to the contracting party aforesaid."

"If, however, in the case previously mentioned, the Power attacking were to be upheld by Russia, whether by way of active cooperation or by military measures that should threaten the Power attacked, then the obligation of reciprocal assistance with entire military forces — obligation stipulated in Article I of this Treaty — would immediately become executory, and the military operations of the two high contracting parties would also, in such circumstances, be conducted jointly until the conclusion of peace."

Ex-Chancellor Prince von Bülow in his book on 'Imperial Germany' thus describes the purpose and results of the alliance: "It was neither the desire of conquest nor unsatisfied ambition that brought the states of the Triple Alliance together and keeps them united. The three mid-European states are bound to each other by the firm resolve to maintain the existing balance of power in Europe, and should a forcible change be attempted, to prevent it if need be by force. The united strength of middle Europe stands in the path of any revolution — any European policy which might elect to follow the courses pursued by Louis XIV or Napoleon I. This alliance is like a mighty fortification dividing the continent in two.

"The founders of the Triple Alliance intentionally created a guarantee of peace. They have not been disappointed in their hopes, for the steadfastness of the Triple Alliance has more than once in the course of the last thirty years warded off the rising danger of war." He concludes with the observation that "The Triple Alliance as a guarantee of peace has proved its worth for thirty years and this justifies our hopes."

This defense of the Alliance was written shortly before the outbreak of the Great European War since which time Italy has ceased to be a member of it. Italy's position as a member of the Alliance was from the first peculiar, if not unnatural, and it is well known that she joined it with more or less misgiving if not reluctance, largely in consequence, it is said, of pique at the acquisition of Tunis by France. That she should have entered into an alliance with Austria which excised dominion over nearly a million Italians occupying considerable territories to which Italy had never ceased to lay claim and which she still hoped eventually to recover can only be explained by the Ital-

ian suspicion of the designs of Great Britain and France in the Mediterranean region. The alliance by its very nature, therefore, contained the seeds of its own dissolution. The national aspiration for "Italia Irredenta" continued to be a source of irritation between Austria and her neighboring ally, and as time passed the ties which bound them began to snap. The first shock came in 1908 on account of the annexation by Austria of Bosnia and Herzegovina, an act which greatly irritated the Italians who regarded with regret if not fear the extension of Austrian power and influence in the Balkans. The weakness of the bond had already been revealed to the world in 1906 at the Algeciras Conference, when Italy broke away from her allies and acted with Great Britain and France against Germany and Austria-Hungary. Furthermore, Italy's war against Turkey in 1911 and 1912 and her subsequent annexation of Tripoli and Cyrenaica was regarded by Germany, Turkey's protector, with regret, for Turkey in effect was now to all intents and purposes a member of the alliance. Germany had been compelled to stand by and see her Ottoman protége stripped of her possessions by an ally which refused to consult Germany or consider her suggestions. This action of Italy still further revealed how loosely she was bound to her allies and particularly her independence of Germany in the conduct of her foreign policy. The alliance was again weakened by the outcome of the Balkan wars. Although Austria and Italy had acted together in thwarting Serbia's aspirations for an outlet on the Adriatic, in creating Albania an independent state under international supervision, the seeds of future discord between Austria and Italy were sown, since it marked the beginning of a diplomatic struggle between the two powers for control of the newly-established state.

On 8 Dec. 1912 it was announced from Vienna that the Triple Alliance had been renewed "without any change." The announcement created a mild surprise in other countries; in Austria itself it caused a panic on the Bourse and a run on the savings banks in Galicia. The last time the treaty had been renewed was in 1902 for 12 years, and would consequently not have expired till May or June 1914. Conflicting reports stated that the renewal was for 12 years or two terms of six years; also seven years. The Austrian press dwelt on the pacific character of the alliance and declared the renewal as "a clear hint to all whom it may concern." It was recalled that Bismarck had published the terms of the treaty in 1888 at a moment when Austro-Russian relations were strained. Italy, it was known, had two treaties, one with each of the other two contracting parties. In 1912, also, an attitude of growing opposition was manifesting itself in Italy against Austro-Hungarian action with regard to Serbia. In German naval circles efforts were made to give the alliance a definite significance for naval as well as for military defense, in the sense of binding Germany's partners to provide naval "compensations" for the increased military expenditure of Germany in order that the naval power of the Triple Entente (q.v.) might have to be strengthened in the Mediterranean and so, perhaps, be weakened in the North Sea. A more drastic attitude was adopted by a general officer writing in the *Zeit*, a German diplomatic organ (8 Dec. 1912). He argued that Russian boldness had its root in the "infamous alliance" with France, and the situation could only be saved if the Powers of the Triple Alliance adopted the formula that Russia must not be allowed to mobilize, and that the Alliance must fall immediately upon France and crush her before Russia could intervene. One victory on French soil, he stated, would cure Russia of her fondness for the French alliance. The paper editorially declared that these ideas prevailed in a great part of the Austro-Hungarian corps of officers. In any case, it was evident that the renewal of the alliance "without change" left the de facto situation in Europe unaltered. Already in 1902 M. Delcassé, then French Minister of Foreign Affairs, informed the Chamber of Deputies that the Italian government had given the assurance to France that "the policy of Italy as resulting from her alliances was neither directly nor indirectly directed against France" and that "in no case and in no form can Italy become either the instrument or the auxiliary of aggression against this country" (3 July). This inspired prophecy was destined to be verified 12 years later in the European War, when Italy refused to join her allies against France and, in 1915, threw her weight on the side of the Entente Powers. Italy now saw an opportunity to realize her irredentist aspirations by joining in the war against Austria.

Under the terms of the treaty of 1882 between Italy and Austria-Hungary, by which treaty Italy became a member of the Triple Alliance, Italy bound herself in certain circumstances to come to the aid of her allies in case they should find themselves in war with another power or powers. Article III of this treaty reads as follows: "If one or two of the High Contracting Parties should be attacked without direct provocation on their part, and be engaged in war with two or several great powers not signatory to this treaty, the *Casus fœderis* shall apply simultaneously to all the High Contracting Parties." Article IV declares that:

"In the event that a Great Power not signatory to this Treaty should menace the safety of the States of one of the High Contracting Parties, and that the menaced Party should be forced to make war on the Power, the two others bind themselves to observe toward their ally a benevolent neutrality. Each one of them in that case reserves to herself the right to participate in the war, if she should consider it appropriate to make common cause with her ally."

During the negotiations preceding Italy's entrance into the war in 1915 the Italian government contended that these stipulations bound Italy to come to the aid of her allies only in the case of a defensive war. Regarding her allies as the aggressors in the war of 1914 she did not consider, therefore, that a *casus fœderis* existed. Moreover the Italian government complained that the Austro-Hungarian government had violated article VII of the treaty of 1882 by failing to communicate to the Italian government the terms of the Austro-Hungarian demands of 23 July 1914, upon Serbia, which preceded the declaration of war by Austria against Serbia. The answer of the Austro-

Hungarian government that the note to Serbia had not been communicated to the German government, that Germany had not been consulted regarding Austria's relations with Serbia and that the Italian government had been assured that Austria-Hungary had no designs of conquest in Serbia, was not regarded as satisfactory. After protracted negotiations between Italy and Austria-Hungary, in which the Italian government demanded the cession of certain Austrian territories to Italy which Austria at first refused, but afterward partially agreed to but not to take effect till after the war, the Italian Parliament in May 1915 declared that the Triple Alliance had been dissolved by the failure of the Austro-Hungarian government to acquaint the Italian government with the terms of the ultimatum to Serbia. In a note handed by the Italian Ambassador at Vienna to the Austro-Hungarian Minister of Foreign Affairs, the former referred to the Triple Alliance as having been entered into as a guarantee of peace and defense, the observance of which would have sufficed to furnish a solid basis for common and effective action. "Austria-Hungary," the note went on to declare, "in ignoring the obligations existing under the treaty, profoundly disturbed the *status quo* in the Balkans and created a situation from which she alone was destined to profit to the disadvantage of interests of the greatest importance, which her ally had many times affirmed and proclaimed. So flagrant a violation of the letter and the spirit of the treaty,— not only justified the refusal of Italy to place herself on the side of her allies in a war provoked without her knowledge, but at the same time deprived the alliance of its essential meaning and of its reason for existing." See ITALY AND THE WAR; AUSTRIA-HUNGARY AND THE WAR; WAR, EUROPEAN: HISTORICAL INTRODUCTION; DIPLOMATIC HISTORY.

TRIPLE ENTENTE, The. In the literature of international law and diplomacy the term "Triple Entente" has reference to an understanding embodied in certain formal conventions and diplomatic conversations between Great Britain, France and Russia. It differs from the former Triple Alliance (q.v.) between Germany, Austria-Hungary and Italy in that the parties to the latter solemnly bound themselves by a common treaty to act together for the maintenance of the balance of power and the preservation of the European peace, and that in certain contingencies each would lend its armed support to its allies in case of war. The Triple Entente had less of the character of a formal alliance. It did not rest upon a common treaty between the three parties, by the stipulations of which each pledged itself to come to the assistance of the other in case of war, but upon a series of treaties and understandings between France and Russia, between Great Britain and France and between Great Britain and Russia, by which their various differences were settled and by which they agreed to act together in the future in the maintenance of their common interests and that in certain eventualities they would come to each other's assistance with their naval forces in defense of those interests.

Like the Triple Alliance, however, the Triple Entente evolved out of a dual agreement, namely, the diplomatic understanding between France and Russia concluded in 1891. The text of the document embodying the terms of this agreement had never been made public, but its purpose as announced was the maintenance of the peace and the balance of power in Europe. In the following year the Russo-French understanding was strengthened by the conclusion between the governments of the two countries of a "military convention," providing for the joint co-operation of their armed forces against a common enemy, and in 1894 this was succeeded by the conclusion of an alliance (the "Duplice" or "Dual Alliance") between the two governments. The texts of both these two last-mentioned agreements and even their exact dates have likewise been kept secret, but in August 1897, during an exchange of toasts between the Tsar of Russia and the President of the French Republic the existence of the alliance, though not its terms, was publicly announced and proclaimed. This understanding with Russia was no doubt entered into at the instance of France as an offset to the Triple Alliance between Germany, Austria-Hungary and Italy. The idea of *revanche* against Germany for the loss of Alsace-Lorraine had by no means been abandoned by the French, and now that France had been encircled by a group of powers including her old enemy, Germany, bound by a treaty of alliance, she turned her eyes toward Russia, who had her own grievances against Germany, and between whom and France strong economic bonds were being created through huge investments of French capital in the Muscovite Empire and through enormous loans to the Russian government by French capitalists. These advances were cordially received by Russia and thus the alliance was easily concluded.

The alliance between France and Russia was now followed by a *rapprochement* between Great Britain and France, for a century traditional enemies of each other in Europe, Africa and America. For a long time Great Britain, secure in the protection of her fleet, and geographically separated from the continent by the English Channel, had pursued a policy of "splendid isolation," eschewing international alliances and avoiding intervention in the disputes of continental Europe. With her undisputed mastery of the sea she did not need the support of allies to protect her interests at home or in her colonial dominions. But, in consequence of the policy of conscription by which the German army was eventually made the most powerful military organization in the world and in consequence of the rapid building by Germany of a powerful navy which, rightly or wrongly,

Englishmen believed was intended to destroy their supremacy on the seas, the British policy of "splendid isolation" was abandoned and Great Britain like France began to look about for continental allies against the real or fancied designs of Germany. The Fashoda incident of 1898 which brought France and Great Britain to the verge of war with each other was quickly forgotten and the two governments, in the presence of a power which they regarded as a common enemy and which had strengthened its position by alliances, now drew together. In 1903 following an exchange of visits by the heads of the two states and representatives of both Parliaments, the two governments entered into a general treaty of arbitration by which they agreed to settle by judicial methods all disputes arising in the future between them, with certain exceptions. This agreement opened the way for the conclusion in the following year of a closer *rapprochement* and the definite settlement of all outstanding disputes between the two nations, some of which were irritating and of long duration. This *rapprochement* owed its success largely to the *savoir faire* of King Edward VII, whose admiration for French manners and French culture caused his advances to be favorably received by the government of the republic. The skilful diplomacy of Lord Lansdowne, Sir Edward Grey, M. Delcassé and M. Paul Cambon likewise facilitated the bringing about of what came to be known as the *Entente Cordiale*. By a "Declaration" dated 8 April 1904, and cast in the form of a treaty, the old source of irritation between the two countries due to the British occupation of Egypt since 1882 was removed. The government of France agreed that it would no longer oppose the British occupation of Egypt by insisting upon a time limit for the termination of the occupation, in return for which the British government promised to recognize the special interests of France in Morocco, particularly her right to preserve order in that country and to provide assistance, economic, financial and military, to the Moroccan government to enable it to establish the necessary reforms, subject to certain treaty rights of Great Britain therein and subject also to certain interests which Spain by virtue of her geographical position and her territorial possessions on the Moorish coast had in the country. This mutual engagement was to be binding for a period of 30 years, and was to be extended at five-year intervals thereafter unless expressly denounced by one of the parties upon one year's notice.

In the same year the century-old conflict between France and England regarding French treaty rights in the fisheries on the coasts of New Foundland were amicably settled by compromise.

Germany regarded the agreement of 1904 by which France was given a free hand in the commercial, if not the political, exploitation of Morocco — an agreement as to which Germany had not been consulted — as one which ignored her own rights therein and threatened her safety. Following the sudden and somewhat dramatic landing of the German Emperor at Tangier on 31 March 1905 — an incident which was intended to serve notice on Great Britain and France that they would not be permitted to partition the territories of North Africa between them without consulting Germany — a demand was made by Germany that the whole question should be submitted to a conference of the powers interested. The conference met at Algeciras in 1906, but on account of the defection of Italy from her allies (see TRIPLE ALLIANCE) and the lending of her support to England and France, the resulting agreement was a disappointment if not a humiliation to Germany, for it practically confirmed the rights claimed by France. Germany for the moment accepted the agreement formulated by the Algeciras Conference, but subsequently claiming that France was ignoring the principle of the "open door" in Morocco and was interfering with the rights of German subjects therein, the German government sent a warship (the *Panther*) to Agadir in July 1911, ostensibly to protect German interests but in reality, as it was believed in England and France, for purposes of aggression. War between Germany and France for some weeks hung in the balance, but it was averted by two treaties (November 1911) by which France agreed to cede a portion of the French Kongo to Germany, in return for which Germany promised to recognize Morocco as a French protectorate and to withdraw from further opposition to French control therein. During this crisis, England let it be known that she would support France against German aggression upon her rights in Africa. In the following year the *Entente Cordiale* ripened into what was in effect an alliance for certain purposes between Great Britain and France. This understanding was embodied in an exchange of notes between Sir Edward Grey, then British Minister of Foreign Affairs, and M. Paul Cambon, the French Ambassador at London, in which it was agreed that if either government "had grave reason to expect an unprovoked attack by a third power, or something that threatened the general peace, it should immediately discuss with the other whether both governments should act together to prevent aggression and to preserve peace, and if so, what measures they would be prepared to take in common." It was in pursuance of this understanding, of which M. Cambon on 30 July 1914, when the German attack on France was imminent, reminded Sir Edward Grey, that the latter on the 2d of August 1914, informed the French Ambassador that he was authorized by the Cabinet to give assurance that in case the German fleet should come into the channel or through the North Sea to undertake hostile operations against the coasts of France, the British fleet would give all the protection within its power.

Finally, in 1907, Great Britain and Russia, between whom good relations were temporarily strained during the Russo-Japanese War on account of the Dogger bank incident and both of whom had become rivals in Persia, settled their disputes and laid the foundations of an *Entente Cordiale* which ripened into an alliance in 1914. The Anglo-Russian convention of that year, like that between Great Britain and France, eliminated certain long-standing disputes regarding their spheres of influence in the Orient. By the terms of the Convention the northern portion of Persia was declared to be within the Russian sphere of influence, while the southern part was similarly assigned

to Great Britain. In the same year a naval convention similar to that between France and Russia was concluded between the two powers providing for the joint co-operation of their navies in certain contingencies.

Thus as a result of these several conventions and understandings between France and Russia; between England and France; and between England and Russia, the Triple Alliance found itself at the outbreak of the present war confronted by the Triple Entente. Already by 1904 an *Entente Cordiale* between Italy and France had been brought about and when Italy repudiated the Triple Alliance in May 1915 and joined Great Britain, France and Russia in the war against Austria-Hungary, the *Triple Entente* became a quadruple entente, if not an alliance in the strict sense of the word. See also MOROCCO; TRIPLE ALLIANCE.

Bibliography.— See the authorities cited in the article on the TRIPLE ALLIANCE.

JAMES W. GARNER,
Professor of Political Science, University of Illinois.

TRIPLER, Charles Eastman, American inventor: b. New York, 10 Aug. 1849; d. Liberty, N. Y., 20 June 1906. Early in life he became an expert mechanician, and in 1871 constructed several models of canal boats propelled by their own motive power. In 1872 he was engaged on a naphtha engine to be used in launches, its principle being the recondensation of naphtha so that it could be used over and over. Experiments in the field where he afterward became distinguished were also begun at this time. In the early part of 1890 he made his first regenerative coil, and he shortly discovered principles hitherto unutilized in the process of liquefying air. About 1895 he was widely advertised as the discoverer of liquid air. See LIQUEFIED AND COMPRESSED GASES.

TRIPLET, *in music,* a combination of three notes to be played in the time of two. They are joined by a slur and distinguished by having the figure 3 above them.

TRIPOD. This name, signifying generally any three-legged utensil, came to be applied to a bronze altar consisting of a caldron raised on a three-legged stand of bronze. Such was the altar of Apollo at Delphi. It had a round flat plate on the top, on which the priestess sat when giving responses. Tripods of fine workmanship and of precious metal were placed in later times as votive gifts in the temples, especially those of Apollo (q.v.).

TRIPOLI, North Africa, the capital of the Turkish vilayet of Tripoli, situated on the Mediterranean Coast, 100 miles from the boundary of Tunis. It is the Œa of the Phœnicians, and lies in a fertile region, is surrounded with a wall, with its domes and slender minarets, has a pleasing aspect. It is a clean and comparatively well-built city, with a handsome palace of the bey, good caravansaries, public baths, numerous mosques and two Christian churches. It was formerly the centre of a large slave trade but now there are manufactures of carpets and cloths and a considerable caravan trade over Sahara. The exports are esparto, barley, ivory, skins, ostrich feathers, etc. The imports are mainly from Great Britain, being foodstuffs, metals, machinery and hardware. It was in Tripoli Harbor that Lieut. Stephen Decatur in 1804 recaptured and fired the United States frigate *Philadelphia.* Pop. of the town about 30,000; of the district (Tripolitania) 73,000.

TRIPOLI, North Africa, formerly a Turkish province, but since 1912 annexed to Italy, situated along the Mediterranean Coast from Egypt to Tunis, and extending inland from 60 to 600 miles to the Libyan Desert and French Sahara. It consists of Tripoli proper, the semi-detached district of Barca or Benghazi in the northeast and the oasis district of Fezzan in the south, and is bounded on the north by the Mediterranean Sea, on the south by the Sahara, on the east and southeast by the Libyan Desert and on the west by Tunis. The total area of Tripoli and its dependencies is about 406,000 square miles.

Topography.— There are practically no harbors of any importance with the exception of Tripoli, the capital city, as the coast line stretches for over 700 miles in an irregular line and is almost unbroken by protecting headlands or indented with bays. The eastern half forms the Systis Major or Gulf of Sidra and is broken by numerous rocky points, which are, however, of insufficient size to form harbors; the western half, extending from the Gulf of Cabes, or Lesser Syrtis, east to Mesurata Point, is low and sandy. The greater portion of the interior, even up to the Mediterranean shores, is a desert country consisting of sandy plains or naked mountains and plateaus. Two mountain ranges stretch from west to east, running nearly parallel to the coast, to the south the Suara Mountains and to the north the Gharian Mountains, the latter about 20 miles from the coast, having a width of from 12 to 15 miles and consisting for the most part of volcanic rocks and isolated peaks. In the southwestern and southern parts of Tripoli proper is the Hammada-el-Homra, an interminable stony tableland covering about 40,000 square miles and about 1,500 feet above sea-level, south of which is the Fezzan depression, in the oasis of which dwell tribes nominally subject to Tripoli, but practically independent. The eastern part of the country (Barca) is practically a continuation of the desert in the south, the mountains to the north being a continuation of the two ranges in Tripoli proper.

Fezzan.— This section of the country covers an area of about 150,200 square miles. In the northern part are low mountains or hills and sandy plains and a few fertile valleys are in the southern part. To the south, especially in the district surrounding the capital, Muzruk, are numerous oases, which together with the Valley of Wady Lajâl, form the most fertile section of Fezzan, corn and dates being cultivated in large quantities. The most common animals found in the hills are foxes, jackals, gazelles, the ostrich, vulture and falcon. There are no streams of water and but a few natural springs and small lakes, the rainfall being very slight and with long periods intervening.

Barca.— To the western and northern parts of this district, which is about 500 miles long by 400 miles wide, is the elevated plateau of Cyrenaica, which encloses the Gulf of Sidra and which is separated on the south from the Libyan Desert by the Aujila depression, a remarkable chain of low-lying oases. South of this depres-

sion the land gradually rises to a height of 1,200 feet and then again depresses to the level of the desert. The sides and summits of the hills in the east and north are well cultivated and afford excellent pasture.

Climate.— The climate is dry and warm, but healthful, droughts prevailing from May to September and rains from November to March.

Industries.— In the hilly districts a large portion of the land is left for grazing purposes and cattle-breeding has become an important branch of trade, but olives, figs, almonds and other fruits are cultivated to a considerable extent. The coast region in the extreme west, particularly the district of Mesheea, is a fertile fruit and cotton-raising district, the chief products of which are wheat, barley (the chief food of the people), millet, Indian corn, pomegranates, lemons, figs, jujubes, apricots, plums, watermelons, cotton, silk, tobacco, saffron, madder and castor-oil; while from the interior comes senna, dates and galls. Esparto-grass, barley and other grains, straw mats, earthen jars and other manufactures, beside the surplus products of the date and olive plantations, are exported by sea. The principal articles manufactured are carpets, cloaks, etc., sacking, prepared skins, morocco leather, earthenwares, etc. There is considerable trade by caravan with the Sudan, carrying European goods south, and ivory, ostrich feathers, rubber and gold north. The total value of the commerce is about $7,000,000 annually.

Government and Population.— Tripoli, which was until 1912 under the despotic rule of the sultan of Turkey, was then annexed by Italy and divided into two independent districts, Tripolitania and Cyrenaica, with their respective capitals at Tripoli and Benghazi, but in 1915 they were merged in one province and is ruled by a governor appointed by the king. There are courts of first and second instance and appeal. The revenues of the country are raised by direct tribute from the Arabs and district governors, a land tax, a tax on Jews and merchants and on export and import duties. The religion is Mohammedanism and while Arabic is generally spoken, Italian is the official language. The inhabitants are mostly Berber, but Jews are numerous, especially on the coast, Moors in the towns and nomadic Bedouins in the country. The population of Tripoli, including the dependencies, has been variously estimated at from 800,000 to 1,300,000. The town of Tripoli has a population of about 30,000; Benghazi of 35,000. Railways are under construction, over 300 kilometers having been laid.

History.— In ancient times Tripoli belonged successively to Carthage, Numidia and Rome. Later it passed into the hands of the Vandals and Greeks. It was captured in 644 by the Arabs, who turned the state religion from Christianity to Mohammedanism. The city of Tripoli was captured in 1510 by Ferdinand the Catholic and from 1530 to 1551 was under the control of the Knights of Saint John. In 1551 Tripoli became a Turkish province, then fell into a state of anarchy and remained a nest of pirates until in 1835 Turkey reasserted its authority and reduced what had been known as one of the «Barbary States» to a vilayet.

As a piratical stronghold Tripoli became involved with various European nations and finally with the United States. Both England and France sent expeditions against it in the latter part of the 18th century, and after numerous tributes and ransoms to insure peace had been paid by the United States to the «Barbary States» as a whole, a treaty with Tripoli was concluded in 1796 for peace without ransom. The pasha, however, inside of four years broke the treaty, demanding $225,000 and $25,000 annually, and on refusal of payment declared war 14 May 1801. An American squadron under Commodore Dale blockaded the harbor of Tripoli and under Commodore Preble (1803-04) bombarded the port five times. The city of Derme, in Barca, was also captured by General Eaton. Fearing further bombardment from the squadron and disaster by land, as well as disaffection and insurrection among his own troops, the pasha signed a treaty of peace on 3 June 1805. In 1815 Decatur forced the pasha to release all ships and prisoners of whatever nation which he had seized and also to pay all indemnities on pain of having the city destroyed. Since that time several rebellions have occurred, the most notable taking place in 1842 and 1844, but all have been successfully suppressed by the Turkish government. In September 1911 war broke out between Italy and Turkey and an Italian army of invasion occupied the country. On 5 November Italy decreed its annexation; but the struggle continued until 18 Oct. 1912, when by the Treaty of Ouchy, Turkey consented to abrogate her sovereignty and the annexation has been recognized by the great powers. See BARBARY; BARBARY POWERS, UNITED STATES TREATIES AND WARS WITH THE; BARCA; FEZZAN; TURKO-ITALIAN WAR.

TRIPOLI, TRIPOLIS, or TARABULUS, Syria, Asiatic Turkey, a town in the vilayet of Beirut, about 40 miles north-northeast of the city of Beirut and two and a half miles from El-Mina, its port of entry. It is situated at the foot of a spur of Mount Lebanon and at the mouth of the Kadisha. The ancient town was situated on a triangular promontory jutting out into the Mediterranean Sea, and for several centuries continued to occupy that position. Earthquakes destroyed a greater portion of the town in 450 and again in 550; in 638 it was captured by the Saracens; it became an important stronghold at the time of the Crusades, and in 1108 was captured by the Crusaders, after having successfully withstood a siege lasting several years. At that time a large and valuable library was burned. It was destroyed by the Egyptian sultan, Kalaun, in 1289, but soon afterward the town was rebuilt on its present site and now enjoys considerable prosperity. In May 1864 the government powder magazine exploded, destroying a large portion of the town and 300 or 400 lives. Among the buildings are a custom-house, foreign consulates, churches, a synagogue, several mosques, an American mission station and girls' school, an orphanage and girls' home of the French Sisters of Charity, a monastery, and an old castle standing on an adjacent height. The main source of income is derived from the export of raw silk, sponges, ivory, sugarcane, olive-oil, cotton, wool, ostrich feathers, tobacco, galls, cochineal, soap, etc. Pop. about 30,000, mostly Mussulmans.

TRIPOLI, a porous, silicious rock, probably formed by the weathering and leaching of chert beds. It occurs abundantly in Missouri, southern Illinois and western Tennessee. The tripoli usually consists of over 98 per cent of silica (SiO_2). Large blocks are used for filter stones. The finer material is ground into tripoli flour, used largely in scouring and polishing preparations. The term tripoli is incorrectly used for tripolite (q.v.) or diatomaceous earth.

TRIPOLI AND INFUSORIAL EARTH. See MINERAL PRODUCTION OF THE UNITED STATES.

TRIPOLITAN WAR, in American history, the name applied to a war between the United States and Tripoli in 1801–05. It was caused by the refusal of the United States to increase its payment for immunity from the depredations of the Tripolitan corsairs. After several engagements peace was concluded 4 June 1805.

TRIPOLITE, a name applied to a silicious ooze composed chiefly of silicious shells of diatoms and hence often called diatomaceous earth or wrongly infusorial earth. It resembles clay or chalk, but is a little harsh between the fingers and scratches glass. It often forms thick deposits below peat swamps. In the Miocene beds of the Atlantic Coast is a more or less impure diatomaceous deposit over 200 feet in thickness. Not to be confused with tripoli. See TERTIARY; DIATOMS.

TRIPOS, a term applied in Cambridge University, England, to the list of successful candidates for honors in the final examinations of the different departments of the university; also the honor examination. The word is supposed to be derived from the fact that the candidate for honors formerly sat on a three-legged stool (tripod or tripos) during his disputation with the professor.

TRIPP, Bartlett, American diplomatist: b. Harmony, Me., 15 July 1842. He was graduated at Waterville College (now Colby University) in 1861 and completed a law course at Albany in 1866. He practised first at Augusta, Me., but in the spring of 1869 removed to Yankton, Dak. In 1877 he served on the commission appointed to revise and codify the laws of Dakota and was president of the first convention that drafted a constitution for the new State of South Dakota. During 1885–89 he was chief justice of the Territory and in 1893 was appointed United States Minister to Austria. Returning from his diplomatic post in 1897, he was, two years later, appointed chairman of the commission having in charge the settlement of complications arising between England, Germany and America over the affairs of Samoa.

TRIPTOLEMUS, trĭp-tŏl'ĕ-mŭs, in the Greek myth, the son of Celeus, king of Attica, and of Metaneira. The goddess Ceres loved him and wished to make him immortal, but was prevented through the meddling curiosity of his mother. She, however, taught him plowing and agriculture and instructed him how to sow corn and make bread. She also gave him her chariot, drawn by two dragons, in which he traveled over the earth and distributed corn to all the inhabitants of the world. He is the hero of the Eleusinian mysteries and founder of the Thesmophorian celebration. In the Attic Eleusinian fable he is represented as the judge of the dead.

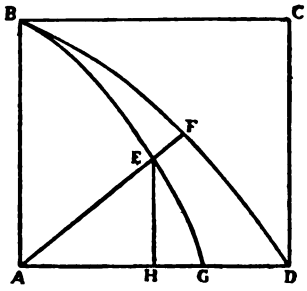
TRIPTYCH, trĭp'tĭk, *in art,* a picture, carving or other representation in three compartments side by side; most frequently such as is used for an altar-piece. The central picture is usually complete in itself and the designs on either side smaller.

TRIREME, *in classical antiquity,* a large galley or war-vessel with three benches or banks of oars on a side, a common class of warship among the Greeks, Romans, Carthaginians, etc. The trireme was usually provided with a large square sail, which could be raised during a fair wind to relieve the rowers, but was not employed in action.

TRISACRAMENTARIAN, a name given to those Lutherans and other Protestants who maintained that the sacraments of Baptism, the Lord's Supper and Penance were necessary to salvation. This opinion was held by some Lutherans at Leipzig and was advocated in England in the "Institution of a Christian Man," published in 1536.

TRISAGION. See DOXOLOGY.

TRISECTION OF AN ANGLE (from Lat. *tresectus,* cut in three parts), a famous problem in mathematics. It was first investigated by the Sophists and Hippias of this school invented the quadratrix by which any angle



may be trisected. In the figure let BD be the quadrant of a circle, BG be the arc of the quadratrix and the construction involve the relation $\frac{DB}{FD} = \frac{BA}{EH}$. Then by dividing B A into segments having any given ratio, the quadrant or any arc BD can be divided into arcs having the same ratio.

TRISMEGISTUS. See HERMES TRISMEGISTUS.

TRISMUS NASCENTIUM (Lat., lockjaw of the newborn), a form of lockjaw, usually fatal, occurring in children a few days after birth. See TETANUS.

TRISSINO, Giovanni Giorgio, jō-vän'nē jōr'jō trēs-sē'nō, Italian author: b. Vicenza, 18 June 1478; d. Rome, 8 Dec. 1550. He studied the Greek language under Chalcondylas and became also a graceful Latin and Italian writer. At a mature age he was employed by Popes Leo X and Clement VII upon several diplomatic missions. He wrote 'Sofonisba,' the first Italian regular tragedy; 'L'Italia Liberata dai Goti,' an epic in blank verse; and 'La Poetica,' a treatise on poetical art. To his suggestion is attributed the present method of

writing the *v* and *j* of the Roman alphabet different from the *u* and *i* with which they were before confounded. He also endeavored to introduce distinct signs for the different sounds of *o* and *e*.

TRIST, Nicholas Philip, American lawyer and diplomatist: b. Charlottesville, Va., 1800; d. 1874. He studied at West Point but left the Military Academy without graduating; studied law with Thomas Jefferson; in 1824 took a clerkship in the United States Treasury Department and in 1829 became private secretary to President Jackson. He was consul at Havana in 1834–36 and in 1845 was made chief clerk in the Department of State. On 15 April 1847 President Polk appointed him special agent to negotiate a peace with Mexico, American successes having practically determined the result of the war with that country. (See MEXICAN WAR, THE). A quarrel with General Scott hindered the performance of his mission and his efforts were unavailing until the new government succeeded that of Santa Ana. Meanwhile Trist's commission had been canceled; but having become reconciled with Scott, he followed his counsel and continued the negotiations, which resulted in the Treaty of Guadalupe-Hidalgo (q.v.).

TRISTAN, TRISTRAM or **TRISTREM,** the central figure of a circle of Celtic myths, which with modifications subsequently appeared in all European literatures. See ARTHURIAN ROMANCES; MORTE D'ARTHUR; TRISTAN.

TRISTAN, a courtly epic written by the Middle High German poet Gottfried von Strasburg about 1210. Like most courtly German epics it is a free rendering of a French source, in this case that of the *trouvère* Thomas of Brittany, the master of the *aventiure,* as Gottfried calls him. It tells the story of a pair of unfortunate lovers, Tristan and Isolt, who are constrained by a love potion to love one another against their will. 'Tristan' belongs to the Bretonic cycle of sagas and reflects the struggles between the Bretons of Cornwall and the Viking kingdom of Ireland. The earliest version is that of the Norman minstrel Berol, which was translated into German by Eilhart von Oberge about 1170. Gottfried knew this version but considered that of Thomas to be more accurate. This version of Thomas appears also in the form of a Norwegian prose saga about 1226 and of an English poem, 'Sir Tristrem,' about 1300.

As Gottfried tells the story, Tristan was the child of Riwalin of Parmenie and Blanchefluer, sister of King Mark of Cornwall. His parents died early, his mother in giving him birth, and he was brought up by a faithful vassal named Rual, who taught him many languages and trained him in all knightly arts. When the lad was 15 he was abducted by Norwegian traders and landed on the coast of Cornwall, where he was taken to his uncle's court, although neither was aware of the relationship. Here he soon became a favorite and was made a knight. Later he fatally wounded the giant Morolt, who had been sent by the king of Ireland to collect tribute long overdue. A splinter of Tristan's sword remained in Morolt's skull. Tristan himself was wounded, and, as his wound would not yield to treatment, he set out disguised as a minstrel to the court of Queen Isolt of Ireland, who was famous for her healing arts, but whose brother Morolt he had slain. Here he was healed by the queen and spent sometime instructing her daughter Isolt in the art of music. On his return he praised the beauty of the fair princess so highly that King Mark was persuaded to make her his bride. Tristan is sent as the messenger, succeeds in ridding the land of a fell dragon, and receives as his reward the hand of the king's daughter, which, however, he claims for his uncle and not for himself. Meanwhile he is recognized as the slayer of Morolt by the missing splinter in his sword, but paints the advantages of a union with King Mark in such glowing colors that he succeeds in reconciling the relatives of the dead giant. On the voyage to Cornwall, Isolt and Tristan, through a mistake of the maid Brangaene, drink of a love potion prepared by Queen Isolt for her daughter and King Mark. For a time the two young people struggle bravely against the overpowering passion which steals over them, but finally abandon themselves to the enjoyment of their love. Instead of confessing their secret to King Mark, they conceal it, and after Isolt becomes the king's bride, continue their clandestine meetings. Again and again they are suspected and are finally caught, but Isolt succeeds in clearing herself by a trick at the trial which is held to decide the question of her guilt. Again detected in a meeting, Tristan is banished and goes to Arundel, where he marries a second Isolt, Isolt "of the white hands"; but because of his love for the first Isolt he lives with the latter in chastity. Here Gottfried's poem breaks off. It was continued and finished by two other poets, Ulrich von Türheim, a Swabian, and Heinrich von Freiberg, a Saxon, who relate how Tristan, once again wounded, sends for his love Isolt. She hastens to his side, but his wife Isolt, prompted by jealousy, declares that the vessel carries a black sail instead of the white one agreed on if Isolt were coming. Tristan succumbs to the shock and Isolt on landing throws herself on the body of her dead lover and dies of a broken heart.

The poem is justly famous among mediæval epics for its wonderful psychological analysis, its masterly portrayal of the struggles of the two lovers against their ill-fated love and the beauty and limpidity of the verse. It is very long, nearly 20,000 lines, but it does not weary us, as do many courtly epics, with lengthy descriptions of armor and dress. The best editions are those of Bechstein (two vols., 3d ed., 1890), W. Golther (Stuttgart 1889) and K. Marold (Leipzig 1906). It has been translated into modern German by H. Kurz (1844), by Karl Simrock (1855); but finest of all is a free rendering by W. Hertz (5th ed., 1911). An English prose translation has been made by Jessie L. Weston (1899). Matthew Arnold modernized it under the title of 'Tristram and Iseult' and Swinburne unblished in 1882 his 'Tristram of Lyonesse,' the best modern epic version of the old saga. Many German modernizations exist, among the most important of which are the epic by Karl Immermann (1840) and Richard Wagner's beautiful music drama 'Tristan and Isolde' (1850). Consult Golther, W., 'Tristran und Isolde in

Dichtungen des Mittelalters und der Neuen Zeit' (Leipzig 1907).

D. B. SHUMWAY.

TRISTAN DA CUNHA, trĭs-tăn' dä koon' yä, or **D'ACUNHA,** a group of three small islands in the south Atlantic Ocean, belonging to Great Britain, and situated in lat. 37° 6' S., and long. 12° 2' W., about 2,000 miles west of Cape Town and 3,000 miles east of Bahia Blanca, on the South American Coast, probably the most isolated inhabited spots on the globe. The islands are named Tristan, Nightingale and Inaccessible. They are peaks of sunken mountains, for nearby soundings go below 6,000 feet and not far away to 12,000 or more. The principal and only inhabited member of the group, Tristan, is 16 square miles in area. It is an extinct volcano rising almost abruptly to a height of 8,200 feet. There is a fine stream and a fresh-water lake. The first permanent settlement was in 1810 and the population is now about 100. The people are moral and hospitable.' The climate is mild, but wet. Cattle, sheep and vegetables are raised. The island was discovered by the Portuguese navigator Tristan da Cunha in 1506 and in 1817 was taken possession of by Great Britain. Pop. about 100.

TRISTEARIN. See STEARIC ACID.

TRISTRAM, Henry Baker, British clergyman and writer: b. Eglingham, 1822; d. 1906. Educated at Lincoln College, Oxford, he became rural dean of Durham (1880) and traveled extensively thereafter. Among his more noted writings are 'The Land of Israel' (1865; 2d ed., 1882); 'Natural History of the Bible' (1867; 5th ed., 1880); 'The Land of Moab' (1873; 2d ed., 1874); 'Eastern Customs in Bible Lands' (1894), etc.

TRISTRAM SHANDY. 'The Life and Opinions of Tristram Shandy, Gentleman,' by the Rev. Laurence Sterne (1713–68), one of the most famous masterpieces in English fiction, was begun in 1759 by way of relieving the author's mind during his wife's attack of insanity. The first instalment was refused by Dodsley in the autumn of 1759 and was privately published by the author in 1761. It had such instant success that a second edition was published in April. Succeeding volumes followed rapidly, the sixth volume appearing in December 1761, but thereafter there were longer intervals, the ninth and last volume being completed late in 1766 (published in 1767), on Sterne's return from a trip through France and Italy, which gave him material for 'A Sentimental Journey.'

In spite of, perhaps because of, its popularity, 'Tristram Shandy' received, as it has since continued to receive, much adverse criticism. This was based on the minor grounds of formlessness and lack of definiteness and realistic sense and for the more important reasons of alleged indecency. Dr. Johnson condemned it for the latter fault and it was also made the subject of burlesque and irony. Sterne, however, continued writing in his own vein and was rewarded with immediate and permanent reputation as an original humorist of high rank. With Richardson, Fielding and Smollett he is usually regarded as one of the four great novelists of the 18th century.

'Tristram' remains one of the most difficult of books to describe. Generally speaking, it belongs to the discursive, digressive, rambling, *intime* kind of novel best represented by Rabelais and Cervantes, to whom Sterne constantly makes acknowledgment, and it is doubtless the prototype of such modern and more decorous novels of the whimsical kind as 'The Autocrat at the Breakfast Table.' It is, however, unlike its originals, in that it apparently lacks the general and satirical purpose that modern critics have discerned in Rabelais and Cervantes, and because its picaresque type of adventure is almost always mental rather than physical. It is an account of the humors of odd people of vivid personality and ways of mind and it is replete with the wit and humor of special situations, persons and habits. It is the vehicle for Sterne's wit, sentiment, whims, humor, learning and notions about various particular things. So far as the author expressed his purpose, such passages as the following tell what he is trying to do: "'Tis to rebuke a vicious taste, which has crept into thousands besides herself — of reading straight forwards, more in quest of the adventures than of the deep erudition and knowledge which a book of this cast, if read over as it should be, would infallibly impart with them. The mind should be accustomed to make wise reflections and draw curious conclusions as it goes along." (Ch. 20). "My work is digressive and it is progressive too — and at the same time." (Ch. 22). "Writing, when properly managed (as you may be sure I think mine is), is but a different name for conversation. As no one who knows what he is about in good company, would venture to talk all — so no author who understands the just boundaries of decorum and good breeding would presume to think all: the truest respect which you can pay to the reader's understanding is to half the matter amicably and leave him something to imagine, in his turn as well as yourself." (Ch. 36).

More concretely, the characters are the important thing. Only 10 figure directly in this long novel. Walter Shandy, merchant; his wife; his brother, the immortal Uncle Toby; the latter's servant, Corporal Trim; Dr. Slop; Yorick, the parson; Obadiah, the manservant; Susannah, the maid servant; the Widow Wadman, Toby's inamorata; and Bridget, her maid; besides Tristram, the showmaster. Numerous lay figures, Didius, Kysarcius, Phutatorius and others, are named from time to time to set off these principal characters, but they never actually appear; and there are many illustrative and digressive stories, as that of the nose and the excellent episode of Le Fever. Nearly half the book is taken up with the prenatal surroundings of Tristram,— of the Shandy family the articles of marriage settlement, the local *accoucheurs,* and other such matters, and of these, the discourses of Mr. Shandy, Uncle Toby, and Dr. Slop, while awaiting the birth of the hero, form a large part. Uncle Toby, the most famous character in the book and one of the most enjoyable creations in literature, is characteristically described by his hobby-horse, playing at fortification and the art of besieging towns. He responds chiefly to such ideas; and yet such is Sterne's art that Toby remains immortal for his simple and generous nature. 'Tristram' is practically without story

or plot, the only connected episode being that about the middle of the novel the hero is born with a broken nose and is misnamed Tristram, to the great grief of his father. Otherwise it is all quiddity, disgression, eccentricity and interlude. Of the three hundred odd chapters, some have only a line or two, and no one chapter may be said directly to follow its predecessor. Consult the 'Life of Laurence Sterne' by Percy Fitzgerald, the biographical criticism by Paul Stapfer and H. D. Traill in the 'English Men of Letters' series, as well as the usual histories of English literature and the 18th century.

WILLIAM T. BREWSTER.

TRITHEISM, the doctrine that there are three Gods, instead of three Persons in the Godhead. It has been taught both in the early Christian period, and in recent times, although so far as known to the public it has no present advocates. The Gnostics, according to Cyril of Jerusalem, were the first to teach it. A similar doctrine was formulated in the 6th century by Ascugnages of Constantinople, after whom one of his pupils, Philoponus, founded a tritheistic sect, which was followed by another sect called Cononites. Tritheism seems to have been dead or dormant for several centuries, until Rosellinus, in the 11th century, brought it forward in a novel form. He taught that the name of God was the abstract idea of a genus containing the three Persons, the Father, the Son and the Holy Ghost. Having been condemned by the Council of Soissons in 1092 he recanted. Tritheism was not heard of again until 1691, when Dr. Sherlock, Dean ot Saint Paul's, London, maintained that "there are three infinite and distinct minds and substances in the Trinity." This teaching was condemned by the heads of the houses at Oxford, as "false, impious and heretical," and the controversy which followed was suppressed by an order in council.

TRITHEMIUS, Johannes, German Catholic theologian and historian: b. at Trittenheim near Treves, 1462; d. at Würzburg, 1516. He was christened Heidenberg but was called after his birthplace. He entered the Benedictine monastery at Sponheim and became its abbot (1483) but his strict rule made him unpopular and he exchanged for the monastery of Saint James at Würzburg. Of his numerous writings his letters were published in 1536 and his sermons in 1576. He was a pioneer author in German church history. Consult Janssen, Johannes, 'History of the German People at the Close of the Middle Ages' (Eng. trans. by A.M. Christie, London, 1896).

TRITICUM, a genus of grasses (q.v.), one species of which (*T. vulgare*) is wheat (q.v.). See GRASSES IN THE UNITED STATES.

TRITOMA, a florist's name for a genus (*Kniphofia*) of African plants of the family *Liliaceæ,* one of which (*K. aloides*) is also widely known as flame-flower, red-hot-poker-plant, torch-lily, etc., and is planted among shrubbery that needs an enlivening color between midsummer and the coming of frost. The "bulbs" send up long, narrow, radical leaves from among which the rocket-like spikes of flamboyant red flowers rise four or more feet. North of Washington the plants are usually taken up and stored during the winter, and in places where the ground is likely to freeze and thaw alternately they should be mulched. They succeed well in any well-drained, warm, loamy soil well protected from wind. Ordinary care in cultivation and fertilizing is sufficient. This species has a score or more of named varieties.

TRITON, trī'tŏn, *in Greek mythology,* son of Poseidon and Amphitrite, with whom he lived in a golden palace at the bottom of the sea. The Triton Sea, a fabled ocean in Africa, appears to be his haunt in the Argonaut cycle. He is variously described, but his body is generally a compound of the human figure above with that of a dolphin below. He is also horned and prick-eared as if an ocean satyr. He carries a large shell, which serves him as a horn on which he blows loudly to rouse the waves, or softly to assuage their fury. Numerous tritons sometimes appear, creatures who in addition to the torso of a man and the tail of a dolphin prance through the billows with the forefeet of a horse. A most beautiful example of this conception is the 'Triton and Nereid' of the Vatican, in which Triton amid a group of sportive Cupids is carrying off a Nereid. Consult Escher, 'Triton, und seine Bekämpfung durch Herakles' (1890); Brunn, 'Griechische Götterideale' (1893).

TRITON. See TRUMPET-SHELL.

TRITYLODON (from the Greek, meaning "three knotted teeth"). A mammal from the lower Jurassic of South Africa; primitive and multituberculate, seemingly resembling the cynodont reptiles with which it has been classed.

TRIUMPH, a solemn procession granted to a victorious general of ancient Rome. It was bestowed only on one who had held the office of dictator, consul, or prætor, and after a decisive victory over foreign foes, or on the complete subjugation of a province. On the day of the triumph all the temples were thrown open; every shrine was decorated with garlands, and every altar smoked with incense. The general assembled his soldiers without the city, delivered to them a commendatory oration, and distributed rewards and money as their share of the spoil of the enemies. He then mounted his car and advanced to the triumphal gate (*porta triumphalis*), where he was met by the senate, and the procession was formed and marched along the Via Sacra to the Capitol. It was led by the senate, headed by the magistrates, and included a train of carriages laden with spoils — models of captured forts and cities, pictures of the country conquered, trumpeters and flute-players, white bulls or oxen destined for sacrifice, attended by priests with their insignia and implements; the most distinguished captives, etc. The triumphant general rode in a circular chariot drawn by four horses; in his right hand he bore a laurel bough, and in his left a sceptre; he was attired in gold-embroidered robe and a flowered tunic, and his brows were encircled with laurel. In the car he was accompanied by his children of tender age, and sometimes by very intimate friends. A public slave held over his head a gold Etruscan crown ornamented with jewels. The legates, tribunes and equestrians, with the grown-up sons of the conqueror, followed on horseback. The infantry followed

in marching order, their spears adorned with laurel, shouting, *Io triumphe!* singing hymns to the gods, and praising or ridiculing their general, according to the license of the day, as their humor might dictate. As the procession ascended the Capitoline Hill some of the captives were withdrawn from it and conducted to prison to be put to death. As soon as their execution was intimated the victims were sacrificed, offerings presented to Jupiter, and the general and his friends parted in the temple, returning home in the evening accompanied by flutes and torches and a crowd of citizens. Sometimes when the spoil was great the procession extended over more than one day. The *ovation* was a lesser triumph, so called because the sacrifice on the occasion was a sheep. The general entered the city on foot, and was not attended by the senate. He was preceded by flutes, but not by trumpeters, and was not necessarily accompanied by his army. Consult Mommsen, 'Romisches Staatsrecht' (1887).

TRIUMPHAL ARCH. See ARCH, MEMORIAL AND TRIUMPHAL.

TRIUMVIR, in ancient Rome, one of the three men united in office. The triumvirs were either ordinary magistrates (as the *triumviri capitales*, who were police commissioners, having charge of the jails, and acting as magistrates, the *triumviri monetales*, who were commissioners of the mint, and had the charge of coining money), or they were extraordinary commissioners appointed to jointly execute any office. The term is specifically applied to the members of the two triumvirates. See TRIUMVIRATE.

TRIUMVIRATE, an office administered by three men (*triumviri*). When Cæsar was murdered, Antony, Octavius and Lepidus received power to restore order in the state: they were called *triumviri reipublicæ constituendæ*, and their office the triumvirate. The coalition between Cæsar, Pompey and Crassus is also called a triumvirate, but it was merely a union or conspiracy of three private citizens without the public sanction. See ROME.

TRIVANDRUM, trē-vän'droom, **TRIVANDRAM,** or **TRIUVANANTAPURAM,** India, the capital of the native state of Travancore, situated on the west coast near the southern extremity of India. It has two colleges, good schools and hospitals, also a fine modern palace of the raja, and on the outskirts are a fort, a military cantonment and an observatory. It is connected by a canal with the port of Quillon. Pop. 63,561.

TRIVET (or TREVET), Nicholas. Early English historical writer: b. about 1258; d. about 1328. He wrote extensively, but is chiefly known for his 'Annales' which was edited by Hog for the English Historical Society (1845). This chronicle history of the Angivins is particularly valuable for the reign of Edward I.

TRIVIUM, the name given in the Middle Ages to the first three of the seven liberal arts — grammar, rhetoric and logic. The other four, consisting of arithmetic, music, geometry and astronomy, were called the *quadrivium*.

TROBRIAND, Philippe Regis, BARON DE, French soldier and writer: b. Tours, France, 4 June 1816; d. 1897. He was educated in Paris and elsewhere abroad and came to America in 1841. He was editor (1854–61) of the *Courier des Etats-Unis*. In 1861 he entered the Federal army, playing an important part in the battles of Fredericksburg and Gettysburg and becoming a brigadier-general (1864). He was brevetted a major-general (1865) and later was commissioned a colonel in the regular army. He afterward commanded the districts of Dakota, Montana and Green River. In 1879 he retired. He published a novel and an historical work on the campaigns of the army of the Potomac. Consult Post, M. C. (his daughter), 'The Life and Memoirs of Compte Régis de Trobriand' (New York 1910).

TROCADÉRO. An elevated place opposite the Pont d'Iéna, on the right bank of the Seine. It was named after a Spanish fort near Cadiz captured by the French in 1823. It was used for the exhibitions of 1867 and 1878, for the latter year being laid out as the Palais du Trocadéro. The buildings contain a great concert hall with two towers and in the wings a fine museum.

TROCAR, a surgical instrument consisting of a sharp-pointed rod sliding in a canula or tube, and used in the operation of tapping, or the puncturing of a cavity to drain off fluid. The rod projects a little beyond the canula, and is withdrawn after the combined instrument has been thrust in. Duchenne's trocar is an instrument for removing small portions of tissue from deep parts for the purpose of microscopic study. Durham's or the piloting trocar is a guide for the introduction of a jointed tracheotomy-tube. Aspirating trocars are usually supplied with a stop-cock.

TROCHEE (Lat. *trochæus*, Greek τροχαῖος), in Greek and Latin verse, the name given to a measure, or foot, which consists of a long and a short syllable. See VERSIFICATION.

TROCHELMINTHES, a division of worms, containing a comparatively small number of minute aquatic organisms, characterized by having that larval form denominated a trochophore (see LARVA). It is principally composed of a single class, the *Rotifera* (q.v.), plus two other groups of microscopic and little known marine "worms," the *Dinophilea* and the *Gastrotricha*. Consult Parker and Haswell, 'Zoology' (New York 1910).

TROCHES. A lozenge-shaped pastile containing usually a medicinal substance put up with sugar and mucilage and flavored. They are dissolved in the mouth and are used to act on the throat. The United States Pharmacopœia recognize nine official troches. Ammonium chloride, cubeb, gambir, krameria, liquorice and opium, potassium chlorate, santonin, sodium bicarbonate and tannic acid.

TROCHILIDÆ, the family of the hummingbirds (q.v.).

TROCHOID, *in mathematics* is the path that any point of a circle moving along a plane, and around its centre, traces in the air; so that a nail in the rim of a cartwheel moves in a trochoid, as the cart goes along, and the wheel itself both turns around its axle and is carried along the ground. The word trochoid is derived from the Greek τροχός, from τρεχω run, and εἶδος shape. In mathematical parlance,

the word trochoid conveys the same idea as the word cycloid.

Few curves have afforded finer scope for exercise of modern geometry than the trochoid or cycloid (q.v.). Its properties successively engaged the attention of Roberval, Fernat, Descartes, Pascal, Slusius, Wren, Wallace and Huygens. Huygens rectified this curve as early as 1657; and having afterward discovered the isochronism, or its remarkable property that all bodies along it will descend from any point in the same time and likewise that it produces a similar trochoid by its development, he applied the discoveries to the improvement of the pendulum, and showed how perfectly synchronous vibrations could be procured, theoretically at least, by causing a flexible rod to vibrate between the trochoidal cheeks. Upon this geometrical curve, then, depends the better part of the whole doctrine of pendulums. Huygens demonstrated that from whatever point or height a heavy body oscillating on a fixed centre begins to descend, while it continues to move in a trochoid (or cycloid) the times of its falls or oscillations will be equal to each other. It is likewise the curve of quickest descent — that is, a body falling in it from any given point above to another not exactly beneath it will come to this point in less time than in any other curve passing through those two points. This very singular property of the trochoid with respect to motion was first discovered by one of the Bernouillis in 1697. From this it is easily seen that if any body whatever move in a trochoid by its own weight or swing together with some other force acting upon it all the while, it will go through all the distances of the same curve in exactly the same time, and accordingly pendulums have sometimes been contrived to swing in such a manner that they shall describe trochoids, or near trochoids, and thus move in equal times whether they go through a longer or shorter path of the same curve.

As the curve of quickest descent, the trochoid is understood to assume its inverted position. It is to be noticed that although the trochoid is longer than many curves and the straight line that may connect two points not in the same verticle line, yet it is, of all lines which can be drawn, the one through which a body will fall in the shortest time. John Bernouilli made the enquiry after the curve which possesses the property: "That a body setting out from any point of it, as A, and impelled solely by the force of gravity, will reach another point of it, as B, in a shorter space of time than it could reach the same point by following any other path." To this curve he gave the name brachystochrone, from *βράχιστος* shortest, and *χρονος* time. It is plain from what has been said about the curve of quickest descent alone, that the brachystochrone and the trochoid (or cycloid) are one and the same curve.

This curve possesses an additional historical interest entirely independent of the particular nature of the curve, for the determination of the nature of this line suggested to Lagrange the idea of an entirely new branch of mathematics, the calculus of variations.

The trochoid (or cycloid, under which name the brachystochrone is best known) may be made to assume an endless variety of forms by placing the tracing point *not in* the circumference of the generating circle but *without* or *within it*. The meaning in this article of a curve is the totality of points, whose co-ordinates are functions of a parameter which may be differentiated as often as may be required. Consult Klein, H., 'Elementar Mathematik vom böheren Standpunkte aus' (Leipzig 1909, Vol. II, p. 354).

If the generating point lies upon the circumference of the generating circle, the curve is known as a common trochoid or a cycloid. When the point is without the circumference of the generating circle, the resulting curve is called curtate or contracted. If the point of generation lies within the circumference of the generating circle, the curve is called a prolate or inflected trochoid or cycloid. In all three instances the wheel or generating circle is thought of as rolling along a straight line in a single plane. For trochoids otherwise conditioned by the surface over which the wheel can roll see ROULETTE; HYPOCYCLOID; CYCLOID.

One more fact in connection with this interesting curve may be noted: It is believed by some that birds, such as the eagle, which build in the rocks, drop or fly down from height to height in this curve. It is impossible to make very accurate observations of their flight and path, but there is a general resemblance between it and the trochoid or cycloid, which has led several ingenious men to adopt this opinion. With the further development of photographic observation, this hypothesis may be confirmed or abandoned.

TROCHOSPHERE, a form of larva (q.v.), especially characterizing the *Trochelminthes* (q.v.), but also seen in other of the lower invertebrates. It is a microscopic oval body, with a mouth, short alimentary canal, and anal opening at the lesser end. There is slight evidence of sense organs. Consult Parker and Haswell, 'Text Book of Zoology' (1910).

TROCHU, trō-shü, **Louis Jules**, French soldier: b. Belle Isle, department of Morbihan, 12 May, 1815; d. Tours, 7 Oct. 1896. He was educated at the school of Saint Cyr, entered the army at an early age, and in 1840 was attached to the general staff with the rank of lieutenant. Sent to Algeria in 1846, he was made adjutant to Marshal Bugéaud and after some years of service in the ministry of war, acted in the same capacity with Marshals Canrobert and Saint Arnaud in the Crimea, gaining special distinction in the storming of the Malakoff bastian at Sevastopol. He fought against Austria in 1859 doing excellent service at Solferino, where he held the rank of general of division. Once more in the Ministry of War and in favor with the government, he made himself *persona non grata* by the publication of his 'L'Armée française en 1867,' in which the deplorable conditions prevailing in the army were ruthlessly pointed out and a reorganization of the national forces on the German model was urged. After the outbreak of war with Germany he was made governor of Paris, but placed himself in opposition to the empire, and after the proclamation of the republic, 4 September, became president of the government of national defense, retaining at the same time his office of governor of the capital. In his defense of the city against

the besieging German army he displayed a half-heartedness which his enemies ascribed to timidity, but which was due to his conviction of the hopelessness of resistance. He resigned the governorship a few days before the capitulation of the city, but remained at the head of the provisional government till the meeting of the National Assembly. In his defense he published, 'L'empire et la défense de Paris devant le jury de la Seine' (1872); 'Pour la vérité et pour la justice' (1873); 'La politique et le siège de Paris' (1874).

TROCHUS. See TOP-SHELLS.

TROGLODYTES, the prehistoric cave-dwelling men of Western Europe, Asia, Æthiopia, Egypt, etc. The name is sometimes extended to any savages living in caves. See CAVE-DWELLERS.

TROGON, a bird of the family *Trogonidæ*, of the order *Coraciiformes* or *Coccygomorphæ*, and unique in the structure of the feet, in which the first and second toes are directed backward and the third and fourth forward, whereas in all other yoke-toed birds the first and fourth toes are directed backward. The bill is short, strong and of wide gape; the tail generally long and in some species very long; the feet small and often feathered almost to the toes. They form a well-marked family of insectivorous and frugivorous forest-haunting birds of small size, whose dense, puffy plumage exhibits the most exquisite tints of pink, crimson, orange, brown or metallic green, often relieved by delicate bands of pure white. In one Guatemalan species (*Pharomacrus mocinno*), the long-tailed trogon or quetzal, the tail-coverts of the male are enormously lengthened into waving plumes of rich metalic blue-green, as graceful and marvelous as those of the birds of paradise. This is the "national bird" of Guatemala, a distinction which it owes to its ancient association with the great Mexican deity Quetzalcoatl (q.v.).

Trogons are unable to use their feet for climbing, and usually take their station on the branches of a tree, dashing on insects as they fly past, or on some fruit at a little distance from them, and returning to their seat to eat what they have secured. The family includes about 10 genera and 50 species, which abound in tropical America with a few representatives in Africa and the Oriental region. A single species, the coppery-tailed trogon (*Trogon ambiguus*), just enters the United States from Mexico. It is a magnificent metallic golden-green bird less than a foot in length which nests in holes in trees and feeds upon fruits, insects, small lizards, etc. Consult Gould, 'Monograph of the Trogonidæ' (London 1875); Godman and Salvin, 'Biologia Americana-Centrali' (London 1896).

TROILUS (tro'ĭl-ŭs) **AND CRESSIDA,** (1) A poem by Geoffrey Chaucer, written about 1369 and adapted from Boccaccio's 'Filostrato.' (See TROILUS AND CRISEYDE). (2) A play composed by Thomas Dekker and Henry Chettle, and first acted in 1599. (3) A tragedy by Shakespeare. (4) A play by Dryden printed in 1678.

TROILUS AND CRESSIDA. 'Troilus and Cressida' is probably Shakespeare's most puzzling play. There is a still unsolved mystery about its appearance in the Folio of 1623: it is not mentioned in the prefatory 'Catalogue' of plays contained in this volume, but appears with pages irregularly numbered at the end of the section devoted to histories and before the first tragedy, 'Coriolanus.' A quarto edition, differentiated by two varying title-pages both claiming Shakespeare as author, appeared in 1609; but as early as 7 Feb. 1603, James Roberts had secured a license to publish "The Booke of Troilus and Cressida, as yt is acted by My Lord Chamberlen's men," "when he hathe gotten sufficient authority for yt." Sufficient authority was apparently not obtainable, but the record establishes the date of the play, which is confirmed by an allusion in its prologue to Jonson's 'Poetaster,' known to have been acted in 1601. 'Troilus and Cressida' is thus contemporaneous with 'Hamlet,' and its obscurities, like those of the other play, may be due to its bearing upon the "War of the Theatres" controversy of 1601. Efforts to interpret the play along these lines have, however, been particularly unsatisfactory, though it may perhaps be accepted that the pompous Ajax is a travesty of Ben Jonson. The dissimilarity of 'Troilus and Cressida' to Shakespeare's other work can be overstressed. From the first the poet displays a quality which might make trouble for a romantic dramatist: a mischievous tendency to splash his tender creatures of romance with the salt douche of cynical realism. In 'Love's Labor's Lost' and 'Henry IV' this produces only a pleasurable tingle, in 'Troilus' a decided chill. What most shocks the reader of the present play is the apparent irreverence to Chaucer and to Homer, but neither of these can have been to Shakespeare a particularly holy name. From Chaucer he derived the love story of 'Troilus and Cressida,' a story unknown to the ancients; but Shakespeare was not, as Spenser was, sufficiently antiquarian in his tastes to attain any real appreciation of Chaucer. Homer was probably first made known to the dramatist in Chapman's translation of seven books of the Iliad, published a year or two before this play was produced. The first looking into Chapman's Homer aroused in Shakespeare inspiration far different from that of Keats. He saw in the then fragmentary work not the true grandeur of the tale of Troy divine, the barbaric splendor of Achilles, and the pathos of Hector, but merely Thersites, whose effective grotesqueness can be traced directly to Chapman's lines. Otherwise Shakespeare saw in the Troy story what the various mediæval compilers from Dares Phrygius to Caxton had made of it—a tissue of false romance in which the Greeks were held up to infamy as a race of schemers, rioters and braggarts, and in which the conquest of Troy was the sordid business that Virgil first suggested. The account of Hector's death, revolting to modern readers of Homer, was sound doctrine to most Englishmen of Shakespeare's day. Thus interpreted, the material lent itself not unnaturally to the indubitably powerful drama on the vanity of human wishes which the poet constructed from it. The publisher's preface of 1609 indicates that even when first produced 'Troilus and Cressida' cannot have been successful. Revivals have been most infrequent;

yet a production by the Yale Dramatic Association in 1916, thought to be the only one ever given in America, was eminently effective.

TUCKER BROOKE.

TROILUS AND CRISEYDE. This narrative poem of over 8,000 lines, written about 1380, is the longest and most elaborate work of Geoffrey Chaucer, and is by many considered his masterpiece, though it is by no means so widely known as those immortal 'Canterbury Tales' which have made his name the common property of all English-speaking peoples. As is usual with Chaucer, the main outline of the story is not original; it is, indeed, the gradual growth of perhaps 2,000 years, from Homer to Boccaccio. But Chaucer has made it his own as he made the stories of his Tales and as Shakespeare made the plots of his plays, and "by the alchemy of his genius has transmuted the baser metal into gold." Troilus, son of Priam, king of Troy, faithfully loves the beautiful Criseyde, daughter of the Trojan priest Calchas, who has deserted to the Greeks. Through the intercession of Pandar, uncle of Criseyde and friend of Troilus, the lovers are united, and for three years are supremely happy. At length, Criseyde is transferred to the Greek camp in exchange for a Trojan prisoner, and joins her father. At parting, the lovers vow eternal constancy, Criseyde, especially, assuring Troilus of her unalterable affection. Once in the Greek camp, however, she soon yields to circumstances and transfers her love to Diomede, the Greek. When Troilus becomes convinced of her faithlessness, he seeks revenge upon his successful rival, but fails, and, after performing prodigies of valor, is slain by the enemy. Criseyde and Diomede survive. The story itself is slight, and the action moves slowly; only about 1,600 lines are pure narrative; almost 6,000 lines are dialogue or soliloquy; several hundred lines are descriptive, or purely lyrical, or in the form of the poet's personal comments upon the action and the characters. The emphasis is so much more upon character than action, that the poem might almost be called a psychological novel in verse,—a surprising production for its period, and one that curiously anticipates a favorite literary method of the 19th century. In his story of love, faithlessness and despair, Chaucer treats sympathetically, yet with a sanity, a sense of values, a profound humor and a worldly wisdom that turn the tragedy into comedy, rather ironic yet neither cynical nor bitter. He has gone far beyond his immediate predecessor in the treatment of the story, Boccaccio (whose poem 'Filostrato' he used in part), in characterization, in sympathy, in numberless subtle touches that show the most penetrating observation of both the inner and the outer worlds. He has added elements distinctly English; for, in spite of his humor and his irony, he shows religious earnestness and a strong tendency to moralize; and, in the sphere of sense, he gives us English scenery, especially the May morning which he loved. Greek though the story is supposed to be, the general setting and the tone are distinctly mediæval, with characteristic disregard of "local color" and historic verisimilitude. But as a whole the poem is compounded of elements that lift it out of any particular *milieu* into the universal: love that grows into overmastering passion; devoted and self-sacrificing friendship; the lure of lovely womanhood. Its supreme excellence is its marvelous characterization. Troilus and, especially, Criseyde and Pandar, are unmatched outside of Shakespeare as examples of the interaction of character and circumstances. They show Chaucer's profound knowledge of human traits and motives; each is completely rounded, utterly consistent and convincing. Each reacts upon the others; together they mold the action, which, as in all true drama, moves logically onward to its inevitable conclusion. This is less the material of ordinary narrative poetry than of psychological drama, easy to make over into a play, as might have been done by Chaucer or Shakespeare's time, and as was actually done by Shakespeare in his 'Troilus and Cressida,' though with a curiously cynical degradation of the material. As a masterpiece of sheer poetic craftsmanship, 'Troilus and Criseyde' far surpasses anything that English poetry has to offer before the time of Spenser. Chaucer handles his seven-line stanza (*rime royale*, rhyming *ababbcc*) with an ease and variety of effect, as well as with a variety and richness of music, possible only to a great master. The monotony which might have attended the use of one form through over 1,000 stanzas is obviated by skilful and constant shifting of the cæsura or verse-pause, by a copious vocabulary, and an inexhaustible variety of rhyme. In form, then, as in matter, the poem is essentially great. It must be admitted that as mere narrative it is always prolix; that it is written in a language now archaic; that, since its time, standards of taste and literary methods have often changed; and that some effort must be made to overcome these initial barriers to a full appreciation. When these have been passed, however, it will be found that 'Troilus and Criseyde' remains, after the lapse of over five centuries, a very great work, rich in the essential elements of poetry.

The evolution of the Troilus and Criseyde story, though important and interesting, can here be only briefly indicated. Homer, in the 24th book of the 'Iliad' makes his solitary mention of Troilus as a son of Priam who died before the beginning of the poem. The cyclic poets acted upon this suggestion and developed Troilus into a hero. In the time of Constantine the Great, Dictys Cretensis' book, 'De Bello Trojano,' in which Troilus figures largely, was translated from the original Greek into Latin: and, about 635 A.D., another 'De Bello Trojano,' in which Troilus is a prominent hero, appeared in Latin as a supposed translation from the Greek of a certain Dares Phrygius. It was from Dares that Benoit de Saint Maure, troubadour to Henry II, king of England, obtained much of the material for his poem of 30,000 verses, which turns the story into a mediæval romance, and first introduces the love element by giving Troilus a mistress named Briseida, who figures in the 'Iliad' as the love of Achilles. Guido de Colonna, a judge at Messina, in 1287 translated Benoit's poem into bad Latin. From both Benoit and Guido, Boccaccio derived the material for his poem 'Filostrato' ("one stricken by love"), in which he changes the name of the heroine to Criseida (the golden one), and adds Pandar to the *dramatis per-*

sonæ. Chaucer uses only about one-half of Boccaccio's poem, condensing, amplifying, paraphrasing, ignoring, according to his needs and purpose. He draws also upon both Guido and Benoit, and even Boccaccio's prose romance 'Filocolo,' which is upon an entirely different subject, for certain details.

The standard text of the poem is that edited by W. W. Skeat (in 'Complete Works of Geoffrey Chaucer,' 6 vols., Oxford 1894). Critical works are numerous. Among these consult 'Chaucer's Troylus and Cryseyde compared with Boccaccio's Filostrato translated by William Michael Rossetti' (London 1873; Chaucer Society Publications, 1st series, 44, 65); Price, Thomas Randolph, 'Troilus and Criseyde' (Modern Language Association of America, Publications, Vol. II, pp. 307–322, 1896); Hamilton, George L., 'The Indebtedness of Chaucer's Troilus and Criseyde to Guido delle Colonne's Historia Trojano' (New York 1903); Young, Karl, 'The Origin and Development of the Story of Troilus and Criseyde' (London 1908; Chaucer Society Publications, 2d series, 40). Chapter VI of Robert K. Root's 'The Poetry of Chaucer' (Boston 1906) gives a fair and interesting criticism of the poem.

MARION TUCKER.

TROJAN WAR, The. According to Greek legend a 10 years' war carried on by the confederated Greeks led by Agamemnon (q.v.), the king of Mycenæ and Argolis, against the men of Troy with their allies. The purpose of this war was the recovery of Helen, wife of King Menelaus of Sparta, who had been carried off by Paris, one of the sons of Priam, king of the Trojans. The earliest and latest dates that have been assigned for this struggle are almost two centuries apart, the former being 1335 B.C., the latter 1149 B.C. The commonly accepted date is that of Eratosthenes, 1183. The story is that there was a gathering of the gods and goddesses, and that Eros flung a golden apple among them, addressed to «The Fairest.» Paris was given the task of deciding who was fairest, and of course got into trouble, for he named Aphrodite (q.v.) in order to gain her assistance in securing Helen. He won her, but obtained the everlasting animosity of Juno and Minerva, who aided the expedition of Agamemnon by every means in their power. Achilles, Odysseus, Ajax, Diomedes (qq.v.) and other famous adventurers, with more than 1,000 ships and 100,000 troops, sailed for Troy and laid siege to the city. The story is told at great length in Homer's 'Iliad' (q.v.) and has been so popular that every educated person feels obliged to read it, and know something of these more or less mythical heroes of ancient Greece. The wonderful adventures of Odysseus, the valor of Ajax and his brother, and the final overcoming of the city by the ruse of building a great wooden horse, surreptitiously filled with soldiers, and ostensibly sailing away, so that the Trojans were fooled into bringing the horse within their gates, has been retold by scores of historians and fiction writers. See TROY.

TROLLEY. See RAILWAYS, STREET.

TROLLING, trōl'lĭng, a method of angling that consists essentially in dragging a bait or bright object through the water, so that fishes are led to mistake it for a moving bait-fish. Trolling is ordinarily practised with a trolling-spoon, so-called because it was originally fashioned from the bowl of an ordinary teaspoon to which a hook was soldered. The modern spoon-bait is a flat piece of metal nickeled or silvered and brightly polished and variously shaped to suit the tastes of the angler so that it will spin or skip along the surface when drawn rapidly through the water. A stout hook projects from one end and the other is attached by a swivel to the line which should be protected for a foot or so by a wire or other snood to prevent it from being cut by the fish's teeth. The spoon or bait is trailed at a considerable distance behind the rowboat, sailboat or launch by which it is drawn. Trolling is effective in fishing for predaceous, surface-feeding fishes, such as pike and pickerel, blue-fish, tarpon, tuna, bonito, various species of mackerel, etc., and also (by employing a copper wire as a substitute for the line) in the capture of maskinonge and lake trout when they retire to deep waters.

TROLLOPE, Anthony, English novelist: b. London, 24 April 1815: d. Harting in Sussex, 6 Dec. 1882. He was a son of Thomas Anthony Trollope, a barrister at the law, by Frances, daughter to William Milton, an English clergyman. His mother afterward became well known in letters. Soon after the birth of this child, the Trollopes settled on a farm — the Orley Farm of one of the novels — at Harrow, where the boy was later put to school. As a poor day-boarder, he was persecuted by the masters and scholars of this famous school, and learned nothing there except a little Latin and Greek. In 1834, he obtained a clerkship in the general post office at London. After seven years' service, carelessly performed, he was appointed clerk to one of the post office surveyors in Ireland. This position, which kept him in the open air, proved most congenial. In order to increase his income, after his marriage in June 1844, to Miss Rose Heseltine of Rotherham, Yorkshire, Trollope turned his Irish experiences into fiction. 'The Macdermots of Ballycloran' (1847), and 'The Kellys and the O'Kellys' (1848), however, were failures; nor would anybody read his historical novel called 'La Vendée' (1850). Because of his good work in Ireland, Trollope was selected in 1851 to reform the letter-carrier system in southwest England. While strolling on a summer evening about the cathedral at Salisbury, the idea came to him of a novel in which should figure bishops, deans and archdeacons. Encouraged by the success of 'The Warden' (1855), he went on with the wonderful cathedral series, which includes, besides the first 'Barchester Towers' (1857); 'Doctor Thorne' (1858); 'Framley Parsonage' (1861); 'The Small House at Allington' (1864), and 'The Last Chronicle of Barset' (1867). When he had finished, the imaginary Barsetshire was as well known as any shire in England. In the midst of this work he wrote several other novels almost if not quite as good, such as 'The Three Clerks' (1858); 'Orley Farm' (1862), and 'Can You Forgive Her?' (1864). Various missions abroad in no wise interfered with his literary activity, for he could write as well in one place as in another. Early in 1858, he was sent to Egypt to make a postal treaty with the Pasha; and on his return he went out to the West Indies to inspect the postal system

there. Before setting out on the latter trip he signed a contract for a book of travel, and when he returned it was complete. 'The West Indies and the Spanish Main' (1859), the author regarded "as the best book that has come from my pen." A sojourn of nine months in the United States resulted in 'North America' (1862). After retiring from the post office in 1866, Trollope visited Australia and South Africa, and published accounts of his travels. In the meantime novel after novel came from his pen. Cathedral life exhausted, he turned to the country gentleman, producing 'He Knew He Was Right' (1869), a study of jealousy; 'The Vicar of Bullhampton' (1870), which caused a sensation; 'The Way We Live Now' (1875), dealing with schemes for getting rich quickly, and other novels of the same general type. The next year he opened a new vein with 'The Prime Minister,' the first of his political novels. In 1879 he published a biography of Thackeray, with whom he had been associated on the *Cornhill Magazine*. After becoming almost the most prolific of English novelists he died, with the manuscript of novels in his desk, on 6 Dec. 1882 at Harting in Sussex, which had been his home for two years. After suffering brief eclipse, Trollope has now come to be regarded as ranking perhaps next to Dickens as a great chronicler of English life and manners among the middle classes. Somewhat deficient in the artistic sense, he possessed wit, humor, pathos and a keen intelligence. See BARCHESTER TOWERS.

Bibliography.— The delightful 'Autobiography' published by his son in 1883, may be supplemented by F. E. Trollope's 'Frances Trollope' (2 vols., London 1895); T. A. Trollope's 'What I Remember' (3 vols., London and New York 1888–90), and 'The Recollections of Edmund Yates' (2 vols., London 1884). Mr. Henry James included a fine appreciation of Trollope in 'Partial Portraits' (New York 1883).

WILBUR L. CROSS,
Professor of English, Yale University.

TROLLOPE, Frances Milton, English novelist: b. Stapleton, near Bristol, 1780; d. Florence, Italy, 6 Oct. 1863. In 1809 she was married to T. A. Trollope, a barrister, but in 1829 she was left a widow with six children. After the death of her husband she came to this country, where she tried to establish a millinery business in Cincinnati, but not succeeding returned three years later to England, where she turned her experiences in America to account by publishing a book on the 'Domestic Manners of the Americans' (1832). The work procured her the reputation in her country of a pungent, if somewhat prejudiced, satirist, but in the United States of an unsuccessful and disgruntled alien; it gave great offense although the justice of some of her strictures is now recognized. Mrs. Trollope followed up this first success with a long series of works, chiefly novels, becoming one of the most voluminous novelists of her day. After 1844 she passed the greater part of the remainder of her life in Italy. The most successful of her novels was 'The Widow Barnaby' (1839), with its sequels: 'The Widow Married' (1840), and 'The Barnabys in America, or Adventures of the Widow Married' (1843). Among her other novels may be mentioned 'Tremordyn Cliff' (1839); 'Petticoat Government' (1859); 'Fashionable Life, or Paris and London,' her last work (1856). Consult 'Life' (1895) by her daughter-in-law, Frances Tiernan Trollope.

TROLLOPE, Thomas Adolphus, English author, eldest son of F. M. Trollope (q.v.): b. 29 April 1810; d. Clifton, Gloucestershire, 11 Nov. 1892. He was educated at Winchester and Oxford. After 1841 he lived in Italy until 1888, when he made his home in Devonshire. During his Italian residence he was a correspondent of the London *Standard* for a time, and Italian correspondent of the New York *Tribune*. His many published works include travels, novels and Italian histories. Among them are 'A Summer in Brittany' (1840); 'A Summer in Western France' (1841); 'La Beata' (1861); 'Marietta' (1862); 'Beppo the Conscript' (1864); 'Lindisfarn Chase' (1864); 'History of the Commonwealth of Florence' (4 vols., 1865); 'Dream Numbers' (1868); 'A Siren' (1870); 'Life of Pius IX' (1877); 'Sketches from French History' (1878); 'What I Remember' (1887–89), the last a sprightly, entertaining autobiography.

TROLLS, trōlz, gnome-like creatures of Norse mythology; giants in Icelandic literature; dwarfs in modern Scandinavian folklore. These latter dwell underground in a hill or mound, in this respect resembling the brownies of Scotland. Trolls are depicted as well disposed to the human race — but given to stealing provisions or even children and women. They are claimed to make themselves invisible, can foresee the future and endow human beings with extraordinary physical strength or wealth.

TROMBONE, a musical instrument of the trumpet class, an improvement on the earlier sackbut. It is a large deep-toned instrument with sliding tubes and is capable within its compass of producing every sound of the chromatic scale in perfect tune. In the orchestra three trombones are used, which harmonize with each other. The range of the alto trombone is from C above the second line of the bass to G above the treble staff; that of the treble trombone is from B, the second line below the bass staff, to G, the second line of the treble; that of the bass from C, the second line below the bass staff, to G, the second line of the treble.

TROMP, trŏmp, **Cornelis,** Dutch admiral: b. Rotterdam, 9 Sept. 1629; d. 29 May 1691. He was a son of Marten Harpertzoon Tromp (q.v.). Entering the service at an early age, he was barely 19 when entrusted with the command of a vessel dispatched against the Algerine pirates, and two years later was made rear-admiral. After distinguished service in the Mediterranean, he fought under the supreme command of De Ruyter against the English under the Duke of York, and after the defeat of the Dutch at Lovestoft (13 June 1665), displayed great skill in effecting the retirement of the vanquished fleet. In the following year he was again under De Ruyter and fought with distinction, but owing to his impetuosity in attacking an English fleet without orders, was retired from active service. Restored to his command in 1673, he displayed consummate

bravery in a series of engagements fought in June and August of that year. After the conclusion of peace with England he was placed in command of a fleet sent to the aid of the Danes against the Swedes, and won several notable victories. On the death of De Ruyter he was made comander-in-chief of the naval forces of the United Provinces.

TROMP, Marten Harpertzoon, Dutch admiral: b. Briel, 1597; d. 10 Aug. 1653. He went to sea at 10, and after a period of service in the merchant marine was taken prisoner by the English and kept in confinement for several years. In 1624 he entered the navy as captain of a frigate, and in 1637 became lieutenant-admiral. On 18 Feb. 1639 he gained an overwhelming victory over a Spanish fleet in the North Sea, off Gravelines, and in October of the same year repeated his exploit by shattering a great Spanish armament in the Downs. War between England and the Dutch broke out in 1652, and he fought an indecisive battle with Blake off Dover, 29 May 1652, but lost a great part of his fleet during a severe storm in the Channel. Supplanted by De Ruyter in the command of the fleet, he was speedily restored, and on 10 December defeated Blake near Dungeness, wresting from the English the mastery of the Channel. A rather apocryphal story represents Tromp as triumphantly parading the Channel with a broom at his masthead. From 28 Feb. to 2 March 1653 he held his own in a running fight with a greatly superior English fleet, and though he sustained some loss, succeeded in bringing into safety a large convoy of merchant ships. On 13 June he was defeated by Dean and Blake in the English Channel, but took the sea again in July, and on 10 August joined battle with Monk in the Channel. The fight was turning in the favor of the Dutch when the Dutch admiral fell, shot throught the heart.

TROMSÖ, trŏm'sė, Norway, capital of the province of Tromsö (area 10,121 square miles), at the northwest, stands on a small island of the same name, which consists of low fertile land and is five miles long. It is an old historical town, has a bishop's see, and a Roman Catholic church, town-hall, arctic museum, etc. Its fisheries are important, and there is considerable trade in oil, sealskin, herrings, dried and smoked fish. There is boatbuilding and rope-making. Notwithstanding its location near the 70° of north latitude, the climate is mild, as the Gulf Stream permeates the surrounding waters. Pop. of town about 7,447; of the island about 81,920; of the "stift or province" 226,145.

TRONA, native hydrous sodium carbonate, or soda ($H_5Na_3C_2O_8$). It has a hardness of 2.5 to 3, specific gravity, 2.11 to 2.14; vitreous, glistening lustre; gray or yellowish-white color; alkaline taste; and is not altered by exposure to a dry atmosphere. It occurs as thin crusts in Fezzan, Africa, in an extensive bed in Churchill County, Nev., and in fine monoclinic crystals at Borax Lake and elsewhere in California.

TRONDHJEM, trönd'yĕm (German, *Drontheim*), Norway, a seaport town on the west coast, the ancient capital of the country, beautifully situated on a bay at the mouth of the Nid, on the south side of the Trondhjemfiord. It has spacious, regular and remarkably clean streets, the houses being chiefly of wood. The most remarkable edifice is the cathedral, which mainly dates from the latter part of the 12th to the end of the 13th century, and is entitled to rank, as a whole, as the most remarkable ecclesiastical structure in the kingdom; it has long been undergoing extensive restorations. Among other buildings are a residence of the royal family, an academy of science, containing a valuable library and antiquarian collections, an arsenal, etc. The manufactures are not of much importance, but there are breweries, distilleries, paper-mills, and shipyards. Two railways now terminate here. The harbor was much improved, the beginning of the century, and about 600 vessels of 350,000 total tonnage enter and also clear annually. The commerce in normal years is about $20,000,000. The trade consists chiefly in exports of timber, dried and salted fish, tar and copper. Pop. 45,335. It is in the amt of Sondre Trondhjem, having about an area of 7,185 miles and population about 148,306.

TROOST, Gerard, American geologist: b. Bois-le-Duc, Holland, 15 March 1776; d. Nashville, Tenn., 14 Aug. 1850. He was educated at the University of Leyden, and was, in 1809, sent by Louis Bonaparte, king of Holland, on a tour of scientific observation to Java. The capture, by a privateer, of the vessel in which he sailed having interrupted this undertaking, he came in 1810 to the United States and settled in Philadelphia where he became a member of the Academy of Natural History, of which he was elected the first president, holding office until 1817. In 1814 he established the first alum works in the United States; and in 1825 joined Robert Owen's community of New Harmony, from which he retired at the end of two years. Removing to Nashville in 1828, he was appointed professor of chemistry, mineralogy and geology in the university there, and in 1831 geologist to the State of Tennessee, both of which positions he held until his death. He published reports on the geology of Tennessee, etc. His mineral collections were the largest in the United States.

TROOSTITE, a variety of the mineral willemite (q.v.), occurring at Ogdensburg, N. J., in large rough crystals usaully of reddish-brown, flesh, red or gray color.

TROPÆOLUM, a genus of annual and perennial herbs of the family *Tropaeolaceæ*. The species, of which there are about 45, are natives of South America, particularly Chile and Peru, whence many have been taken to all the warmer parts of the world to be grown in gardens for their odd, conspicuous flowers. They are mostly climbing vines, with alternate, usually simple, peltate leaves, from the axils of which the generally long-peduncled, irregular, usually yellow, orange or red, sometimes blue or purple, flowers are produced singly. Several species, especially *T. tuberosum*, produce edible tubers which are used for food in the tropics. The leaves and flowers of a few species are used as salads, for which their peculiar peppery flavor especially fits them. Their young, tender pods are often pickled and in this form are frequently employed as a sub-

stitute for capers. The species most used in this way are *T. majus* and *T. minus*, known as nasturtium, Indian cress and yellow larkspur, names which better fit plants of other families. Another species in popular use is *T. peltophorum*, which, like *T. majus*, is commonly employed as a climber upon porches, balconies and banks. The canary-bird flower (*T. peregrinum*) is probably more often grown indoors than out, in the north, *T minus* is a dwarf, non-climbing species which blossoms earlier and more profusely than others; it is frequently used in beds and borders. Few plants are more frequently satisfactory and popular than the nasturtiums. They will thrive in any garden soil if well exposed to the sun, and not allowed to become very dry. Since they are tender to frost they are either sown rather late or are started under glass and transplanted when the weather becomes settled. Especially fine specimens may be propagated by cuttings, and tuberous species should be dug and stored during the winter. The perennials seem to require richer soil than the annuals.

TROPHONIUS, trō-fō'nĭ-ŭs, builder of the temple of Apollo at Delphi. After his death he was reverenced as a hero, and had an oracle in a cavern near Lebadeia in Bœtia. Pausanias describes how, after purifying himself, he was drawn through the mouth of this cave by an unseen power, and details all that he witnessed there. Don Quixote's famous visit to the oracle preserves its memory in modern literature.

TROPHY, *in antiquity,* a monument or memorial in commemoration of some victory. It consisted of some of the arms and other spoils of the vanquished enemy, hung upon the trunk of a tree or a stone pillar by the victorious army. The custom of erecting trophies was most general among the Greeks, but it passed at length to the Romans. It was the practice also to have representations of trophies carved in stone, in bronze or similar lasting substance. In modern times trophies have been erected in churches and other public buildings to commemorate victories or heroic action in war. The term has been extended to describe any group of objects hung on a wall to commemorate an event, industry or activity.

TROPIC-BIRD, a sea-bird of the family *Phætontidæ*, related to the pelican. The bill in these birds is sharp, curved superiorly, and is as long as the head. The two middle feathers of the tail are very long and narrow, giving the birds the names boatswain-bird or marlinspike among sailors. They inhabit the tropical seas and can fly for days together without visiting land, resting and sleeping on the water. A large and well-known species is *Phaeton æthereus*, which averages about two and one-half feet in length, the tail-feathers being about 15 inches. It is most often seen in the Indian Ocean, where it breeds on the Mascarene Islands. The yellow-billed tropic-bird (*P. flavirostris*) is smaller and more often seen in the western Atlantic, since it annually visits Bermuda and the Antilles to breed, laying but a single, heavily blotched egg in a hollow of the beach, or sometimes in a rude nest in a tree. Consult Newton, 'Dictionary of Birds' (New York 1896).

TROPICAL FOREST PRODUCTS. The products of forests are usually divided into two great groups, as follows: (1) Major forest products, such as wood used for construction purposes and for special uses, as furniture, cabinet work, wood used for small articles of all kinds, etc.; (2) Minor forest products include firewood, tannin extracts, dyes, rubber, gutta percha, rattan, bamboo, wood oils, resins and various forest plants that produce medicinal products, like quinine, cocaine, sarsaparilla, epicac, camphor, etc. As a matter of fact, the value of these minor products of tropical forests consumed in the world's markets greatly exceed the value of the major products. Indeed, so great is the demand for some of the minor forest products that many of them have almost entirely become cultivated ones. Ten or 15 years ago while most of the rubber of commerce came from a wild forest tree (*Hevea braziliensis*) of the Amazon valley, approximately 80 per cent of the rubber used to-day is from cultivated plantations of this tree in the Eastern tropics.

Kapoc is the commercial name for the cotton from the so-called cotton tree (*Ceiba pentandra*) and is a native of tropical America, but the chief source of this valuable product, used principally in stuffing mattresses, is from plantations in Java. Formerly the chief source of the Peruvian bark, quinine (*Cinchona* species) was from the wild forests of Ecuador, Colombia and Peru. To-day most of the quinine comes from cultivated plantations in India and Java. The lack of cheap labor in the American tropics is the chief reason why these valuable products are cultivated in the Eastern tropics.

Because the climatic conditions of temperate regions are not favorable for the production of many tropical minor forest products, the temperate markets must always depend on the tropics for most of them unless synthetic products can be substituted. While efforts made to produce synthetic rubber have not proved successful, yet the manufacture of synthetic dyes has greatly reduced the demands for the dye woods of the tropics, hence until the war greatly, but temporarily, stimulated the use of tropical dye woods, the amount of these woods used in the markets is not likely to be greatly increased.

On the other hand tropical woods for construction purposes have not been in demand in the great lumber markets of the world, the United States and Europe, principally because the forest of these regions have light timbers in large quantities that are better suited for general construction timbers than the so-called hardwoods of the tropics. The coniferous woods, or softwoods, of the temperate regions of North America, Europe and Asia stand in sharp contrast with that of the hardwood forests of the tropics. On the one hand coniferous forests occur in pure, or nearly pure, stands that make their lumbering on a large scale more profitable, hence the lumber industry has been highly developed; on the other hand the hardwood tropical forests are more complex in character and usually far away from well-developed industrial regions, hence capital has not been attracted to their exploitation on a large scale. Moreover, because of the great development of the lumber industry, es-

pecially in the United States, there has been an over-production; the surplus finds its way to all parts of the world and large amounts have been absorbed by tropical countries. The contribution that tropical forests have made to the lumber markets has been woods for special uses rather than those for general construction purposes. Many woods of tropical countries are used locally for general construction purposes, that never find their way into outside markets. The study of tropical forests show that while they are more complex in composition than coniferous forests of temperate regions, yet this complexity is not so great as formerly supposed. The complexity is increased by the undergrowth trees that do not reach commercial size. The trees that reach huge size and overtop the undergrowth species are composed of comparatively few species whose woods are little known. Also, a large percentage of these trees produce rather soft hardwoods that are easily worked. Thus, the estimated stand of timber in the Philippines is 200,000,000,000 board feet, more than 100,000,000,000 of which are light hardwoods that can be and are being substituted locally for many purposes to which imported coniferous woods were put. These forests also occur in sufficiently heavy stands to warrant the establishment of fairly large lumbering operations that will reduce the cost of their utilization. A recent estimate of the area and stand of timber in some of the large tropical forest regions is as follows:

FOREST REGION	Forested area in million acres	Stand of timber in billion board feet
Southern Brazil	260	650
Amazon Basin	1,024	3,400
Northern South America	200	500
Indo-Malay Region	320	1,600
Total	1,804	6,150

The forested area of the United States is estimated at 550,000,000 acres, carrying a stand of timber of 2,800,000,000,000 board feet. Thus the Amazon region alone is estimated to have some 600,000,000,000 feet more than is found in the United States.

At the present time it is not possible to connect the market or local name of many of the tropical woods with the specific scientific name of the trees producing them, for much systematic work in botany is necessary before this can be done. Indeed, as in some temperate woods, a group of species stands for the wood. Thus the term oak stands for several species of the genus *Quercus* and the trade term pine refers to a large number of species of *Pinus* and even to many other coniferous woods not of this genus. Also where adjectives are prefixed to the market names, the name may include more than one species; several species of oak produce "white oak," and "southern yellow pine" is the product of a number of species of *Pinus*. The same holds true for tropical woods. An attempt is made below to classify some of the principal groups of tropical woods. These include many of those that are found in American and European markets, and a few that play an important rôle in the countries in which they occur.

I. The Mahogany Family (*Meliaceæ*).—1. The "true" mahogany originally came from *Swietenia mahagoni Jacq.* and seems to be entirely restricted to the West Indies and Southern Florida. Late investigations show that the *Swietenias* of southern Mexico, Central America and, perhaps, Colombia, are two different species and at least some of that from Venezuela is a fourth species.

The wood of the four species is accepted as true mahogany, and when placed on the market usually bears the name of the place or region from which it comes. Thus we have Cuban, Santo Domingo, Honduras, Nicaragua, Mexican, etc., mahogany. Santo Domingo mahogany is considered the most desirable grade. Throughout this range the wood is locally known under the Spanish name of caoba. The different grades of mahogany vary in weight from 35 to 52 pounds per cubic foot, and cannot be considered as very heavy. Mahogany is red in color, beautifully grained, easily worked and is durable. It takes a natural polish, is adapted to stains and takes glue well. The combination of these qualities makes it the furniture wood par excellence of the world. Most of the substitutes of true mahogany fail in one or more of these qualities and hence are inferior.

2. *African Mahogany.*—The growing scarcity of easily-accessible true mahogany has led to the introduction of many woods as substitutes. The best of these belong to the same family (*Meliaceæ*). Under the general name of African mahogany the tropical regions of West Africa have supplied large quantities of mahogany. Perhaps the best known of these is the Gambia or Senegal mahogany (*Khaya senegalensis*, A. Juss.), although other species of this genus and species of the genera *Trichilia, Carapa, Entandrophragma* and a number of species of other families furnish African mahogany.

3. *Spanish cedar, Cigar box wood, Cedro.*—The above are the commercial names of a number of species of the genus *Cedrela* which occur throughout the American tropics from the West Indies and Mexico to Paraguay and northern Argentina. The original Spanish cedar (*Cedrela odorata* L.) appears to be confined to the West Indies and has a strong cedar odor, hence the name. It is used mostly for cigar boxes. Most of the *Cedrelas* of the American continent, known everywhere under the Spanish name of *cedro*, seem not to hold this strong odor when exposed to the air for some time. The wood of *cedro* closely resembles that of true mahogany in many respects, except that it is usually much softer and lighter in weight. The heavier grades are about the same weight as the lightest mahoganies. There is little doubt that some of the so-called mahogany found in the markets is really *cedro*. *Cedro* is a common and much-prized wood in the markets throughout all Latin American countries, especially in Argentina. It is used for furniture and light construction work, principally interior finish of houses. The genus *Toona* (formerly called *Cedrela*) found in parts of the eastern tropics produces woods almost identical with that of *cedro*. In the Philippines a species of this genus (*Toona*

calantas, Merr. & Rolfe) has the common name of *calantas*, and in India another species has the common name of *toon*.

4. *Carapa or Demarara Mahogany* (Guiana), *Andiroba or Brazilian mahogany* (Amazon region).—In the lowlands from the mouth of the Orinoco River (Venezuela), in the Guianas and to and including the Amazon Valley, is found a wood bearing the above names which is the product of *Carapa guianensis* Aubl. This wood resembles mahogany in some respects but is much coarser grained. It makes a good, cheap substitute for this wood, but is locally used for much the same purposes as *cedro*.

Besides the above woods all belonging to the mahogany family, together with others of less importance, there are a large number of species belonging to different families that appear in the markets under the name of mahogany. In all about 60 such species have been listed. The most important of these are discussed below in connection with the family to which they belong.

II. The Locust Family (*Leguminosæ*).—The locust family, represented in our temperate flora by such trees as the black locust, honey locust and others, has a large number of species of soft, hard and very hard woods that are used locally in the tropics for all sorts of purposes, and some of them find their way into temperate markets.

1. *Rosewoods, Jacarandá or Caviúna* (Brazil); *Blackwood* (India).—The name "rose" was applied to this wood because of a fragrant odor resembling that of the rose. Similar woods without the odor also bear this name. The woods are dense, heavy, durable and are dark brown or black in color, sometimes streaked with purple, rose and other colors. Their chief use is in furniture, pianos, inlaying and small turnery objects. The main source of the rosewoods is Brazil. Here the true rosewood of the Rio de Janeiro region is referred to *Dalbergia nigra* Allem, and that of the Amazon region to *Dalbergia spruceana* Hub., but it is known that a number of species of *Machærium* produce rosewood. The rosewoods of Central America are supposed to come from species of *Dalbergia*. A similar wood of Colombia under the name of *negrillo* or *granadillo* is a species of *Machærium*, though the name granadillo is applied to a number of other woods. The Indian rosewood is *Dalbergia latifolia* Roxb. A similar wood (*Dalbergia melanoxylon* Guill. & Perr.), under the name of Senegal ebony, comes from Africa. In a broad sense the *cocobola* wood of Panama (*Dalbergia retusa* Hemsl.) can be classified as a rosewood. Other woods of less importance in different genera of this family and species of other families are often classed as rosewoods. Some of these have the blackish color and others are classified as rosewood because of their rose color.

2. *Padauk* (India); *Narra* (Philippines); *African Padauk* (Africa).—The genus *Pterocarpus* produces a number of woods usually of a beautiful red color, but sometimes yellowish red and even nearly black. These woods have a similar use to those of the rosewoods and are sometimes given the name of mahogany. The chief source of the best *padauk* (*Pterocarpus dalbergioides* Roxb.) is the Adaman Islands (India), though *P. indicus* Willd. and other species of Burma and India and the Philippines produce similar woods. In the Philippines the local name is *narra*. It has been exported to the United States under the name of Philippine mahogany.

3. *Brazilwood; Logwood, or Campeche.* Brazilwood is a reddish yellow wood mainly produced by certain species of the genus *Cæsalpinia*, and perhaps by *Hæmatoxylon brazilleto* Karst. It is exported chiefly as a dyewood. Brazilwood from the eastern tropics was known in Europe before America was discovered. When Brazil was discovered, because of the abundance of this wood along the coast in the region of Rio de Janeiro, the country was named after the wood. *C. sappan* L., and perhaps related species, is the source of brazilwood from the Eastern tropics. It is known in India under the name of sappan-wood and in the Philippines as sibucao. While scattered throughout the American tropics, the chief commercial source is Brazil and the Caribbean Sea region. The source of the wood from Brazil seems to be *C. echinata* Lamck., though there is some doubt about it. It is known locally as *ibirapitanga* or *páo Brazil*, and also has the export name of Pernambuco wood. The brazilwood of the Caribbean region seems to be mostly *Hæmatoxylon brazilleto*. Logwood or campeche (*Hæmatoxylon campechianum* L.) is blood red in color and yields a dye (stain) known as hæmatoxylon. It comes chiefly from Southern Mexico and Central America. It is semi-cultivated in India and parts of the West Indies.

4. *Dividivi* (*Cæsalpinia coriaria* Willd.).—The pods of this tree are rich in tannin and they are exported in considerable quantities principally from Colombia and Venezuela where the tree grows in dry districts where it is wild or semi-cultivated.

5. *Tonka bean* (Guianas and Venezuela); *Cumarú* (Amazon).—The beans of this tree (*Dipteryx odorata* Willd., and one or more closely related species) after being treated in casks of rum, are exported in considerable quantities principally from the region south of the Orinoco River in Venezuela. They are used in making perfumes and flavoring extracts. The wood of *cumarú* is very hard, difficult to work, yellow in color, streaked with red, and is used to some extent in the Amazon region.

6. *West Indian Locust; Courbaril; Algarroba* (Venezuela and Colombia), *Jatahy* (Brazil).—The West Indian locust is the English name for a wood produced by *Hymenæa courbaril* L., although in Brazil, under the name of *jatahy*, besides the above, there are several species of *Hymenæa* that give similar woods. The wood is red with dark streaks. It is used locally but little exported. The different species yield a resin known as South American *copal*, or *courbaril*, which is exported in considerable quantities especially from northeastern Brazil. Bodies of the resin are deposited in the ground on the death of the tree and are thus mined.

7. *Copahyba.*—This is the Brazilian name of a wood similar to the West Indian locust and with the same uses. It is produced by several species of the genus *Copaifera*. The tree produces an oil known as *aciete* or *copaiba* oil that is exported to some extent. It is found also in northern South America and neighboring regions.

8. *Araribia* (Brazil); *Cartan* (Venezuela); *Guayacan jobo* (Colombia); *Amarillo de Guayaquil* (Panama).—This group of woods comes from several species of the genus *Centrolobium*. The woods vary from a bright reddish yellow to yellow streaked with darker color. They are used quite extensively locally, especially in Brazil and deserve to be exported as fine furniture woods.

9. *Acapú*.—The acapú (*Vouacapoua americana* Aubl.) is a reddish brown wood, with dark, almost black, streaks, and very hard and heavy, that comes from the Amazon valley and is exported in some quantities.

10. *Purpleheart, Violet wood; Guarabú or Páo Roxo* (Brazil); *Nazareno* (Panama); *Tananeo* (Colombia).—These woods are generally referred to the genus *Peltogyne* and found from Panama to Brazil, though species of closely related genera may produce some of them. The woods are dark purple, sometimes with violet shades. They are quite extensively used in Brazil and British Guiana for many purposes. Some of them yield an odorous resin used medicinally and a red dye used for textile fabrics. Purpleheart has been exported from British Guiana and neighboring islands.

11. *Balsamo; Balsamo de Tolu* (Colombia); *Oleo or Cabreúva* (Brazil); *Incienso* (Argentina).—The general name of *balsamo* is here applied to a group of woods that come from the genera Myroxylon and Myrocarpus. The woods are dark or yellowish red in color and the bark or wood or both yield oily substances. The bark of the balsamo of Colombia (*Myroxylon balsamum* [L] Harms.) yields a resinous oil, *balsamo de tolu*, that is exported to some extent. The woods are used locally and deserve to find wider markets. The *cabreúva* or São Paulo, Brazil, is probably the most used. The *incienso* of Argentina, a scented wood, is highly valued in Argentina.

12. *Ipil* (Philippines); *Mirabeau* (Borneo and Malay Peninsula).—The genus *Instia* especially *Instia bejugo* [*Colebr.*] O. Ktze. is the main source of the wood. It is yellow when fresh cut but turns reddish brown to chocolate color when exposed. It is highly valued for construction work in contact with the ground. In the Philippines it is one of the principal woods used for railroad ties.

13. *Tindalo* (Philippines).—This wood is the product of *Pahudia rhomboidia* (Blanco) Prain. The wood is yellowish red, becoming very dark with age. It is greatly prized for flooring, fine interior finish and furniture.

14. *Acle* (Philippines); *Pyingado* (Burma).—Both these woods resemble each other closely in structure. In color they are dark brown and resemble in this respect the black walnut. The *acle* (*Albizzia acle* [Blanco] Merr.) is highly prized in the Philippines as a fine furniture wood. The *pyingado* (*Xylia dolabriformis* Benth.) grows in the teak forests and is used extensively for railroad ties.

The above are only a few of the many woods produced by the *Leguminosæ*.

III. Lauan or Dipterocarp Family (*Dipterocarpaceæ*).—From the standpoint of producing lumber for general construction purposes this is the most important tropical family, because the species compose a large percentage of the lumber in the forests in which they occur, and the woods are easily cut and worked. The family is confined to the eastern tropics, especially to Borneo, the Philippines, Sumatra, Malay Peninsula and parts of Burma and India. With respect to their hardness and durability the woods can be divided into a number of groups.

1. *Lauan, Tanguile* (Philippines); *Seriah or Meranti* (Borneo, Malay Peninsula).—This group of woods is found throughout nearly the whole range of the family. Besides the above there are very many local names for the different species which belong to genera *Pentacme, Parashorea*, and certain species of *Shorea*. They are the most abundant of the dipterocarps. The woods of the *lauans* (to use the local Philippine name for the whole group) are all light hardwoods, not durable, as easily worked as pine; locally they are used for all light construction purposes. In regard to color they are classified as *white* and *red lauans*. The latter include *tanguile*. The better grades of the *red lauans* show resemblance to mahogany and large quantities have been shipped to the United States for mahogany. Of these *tanguile* (*Shorea polysperma* [Blanco] Merr.) is the best. In the United States it is usually sold under the name of *Bataan mahogany*. The product of other species, mostly *Shorea negrosensis* Fox., sells in the United States as *Philippine mahogany*. Certain *red lauans* from Borneo are sometimes sold in England as *Borneo redwood*.

2. *Apitong* (Philippines); *Kruen* (Borneo and Malay); *Eng.* (Burma), *and other names for these and other regions*.—This group of woods belongs to the genus *Dipterocarpus*. In contrast with *lauan, apitong* is a moderately, not very durable, hard wood, of a reddish brown color. It finds its greatest use for heavier construction purposes not in contact with the ground.

3. *Yacal* (Philippines); *Selangan batu* (British North Borneo and Dutch East Indies); *Ressak* (Dutch East Indies); *Thingan* (India), *and other local names for these and other regions*.—This group of woods is the product of certain species of the genera *Hopea* and *Shorea*. The yacals are dark brown in color and are the hard, durable woods of this family. They are comparatively easily worked and are most valuable for construction work in contact with the soil and any construction where durability and great strength are required. They are a good substitute for teak in many classes of shipbuilding.

4. *Guijo* (Philippines); *Sal* (India).—These woods are like the apitongs but finer grained and more durable. The *Sal* (*Shorea robusta* Gaertn. f.) is one of the most important timbers of India. The *guijo* (*Shorea guiso* [Blanco] Blume) is one of the most useful timbers of the Philippines.

5. *Borneo camphor; Kapor* (Malay name).—This wood, the product of *Dryobalanops aromatica* Gärtn. yields a substance that closely resembles camphor for which it is sometimes used. It is known only from Borneo, Sumatra, and the southern end of the Malay Peninsula.

IV. The Brazil-nut or Monkey Pot Family (*Lecythidaceæ*).—This family is confined mostly to South America. The woods of the family, while at present little used, promise to play an important rôle in the future lumber industry of South America, because in many

TROPICAL FOREST PRODUCTS

1 Parana Pine (Araucaria braziliana), forest of Southern Brazil. The undergrowth tree is Embura (Nectandra sp.), the timber de luxe of the region. 2 Cedro or Spanish Cedar (Cedrela sp.), in the forests of Southern Brazil. Cedro is one of the most common woods used throughout tropical America. 3 Lapacho (Tecoma sp.), in the Alto Parana region of Argentina. Equivalents of this wood, belonging to closely related species of the genus Tecoma, occur in the forests from Mexico to Northern Argentina. 4 A Lauan or Dipterocarp forest of the Philippine Islands. Among the species in this forest is Red Lauan (Shorea negrosensis), whose wood is sometimes sold as Philippine mahogany in the United States

1 Tanguile (Shorea polysperma), Philippine Islands. Wood of this tree is sold in the United States under the name of Batasan mahogany
2 African mahogany logs in West Africa

places the members of the family are very abundant. The important members of the family have large cup-shaped fruits, called by the English monkey pots. The trees of the family are the giants of the forests, and in parts of the Magdalena Valley, the Amazon Valley, British Guiana and the coastal forests of Brazil they form the most important element in the composition of the forest.

1. *Brazil nut; castanheiro* (Brazil).—The *Brazil nut* (*Bertholletia excelsa* H.B.K.) is one of the largest trees of the Amazon and is the source of the Brazil nuts of commerce. Because of the value of the nuts the wood is little used.

2. *Colombian mahogany, Albarco* (Colombia).—The wood of this tree is the product of *Cariniana pyriformis* Miers. It is abundant in foothills bordering the large rivers. Because of the resemblance to mahogany it has been shipped to the United States under the name of *Colombian mahogany.*

3. *Jequitibá* (Brazil).—This is the product of several species of *Cariniana* (by some authors, *Couratari*) and is abundant in the coastal forests from Bahia to São Paulo, and the interior of the state of São Paulo. The wood is reddish, comparatively soft and would make a better substitute for mahogany than albarco, because it is more easily worked. In Brazil it is used for construction purposes.

4. *Monkey pots, Coco de Mono* (Colombia); *Kakeralli* (British Guiana); *Sapucaya* (Brazil).—This group of woods is the product of several species of the genus *Lecythis* and occurs from São Paulo, Brazil, to Panama. The wood, reddish brown in color, is used locally for construction purposes in contact with the ground, and in Brazil is especially valuable for railroad ties. Several species from Brazil with the name of *sapucaya* furnish the so-called *paradise-nut* of commerce.

5. Other woods in the Amazon Valley worthy of mention are the following: *Matamata* (*Eschweilera matamata* and other species) is a wood highly valued for salt-water construction because it resists well the action of the shipworm (teredo). The *tauarys* are products of several species of the genus *Couratari* and are used locally for shipbuilding.

V. The Laurel Family (*Lauraceæ*).—Besides producing the cinnamon (*Cinnamonum zeylanicum* Breyn.), found in South and West India, and Ceylon where it is extensively cultivated; the *camphor* (*Cinnamonum camphora* [L.] Nees & Eberm.) principally from Formosa; and the *alligator pear*, or *aguacate*, or *avocado* (*Persea americana* Mill.), originating in parts of the American tropics and widely cultivated, this family produces a great variety of timbers found scattered throughout the tropics. In the American tropics many of these timbers occur under the general names of *canella* (Spanish and Portuguese), *laurel* (Spanish) and *louro* (Portuguese). The best-known woods are the following: (1) *Greenheart* (*Nectandra rodioei* Schomb.) found principally in British Guiana from which country it is exported as a first-class wood for salt-water construction purposes. Large quantities of it were used in the building of the Panama Canal. When fresh cut the wood is grayish brown in color but on exposure turns to a dark green or chestnut color. (2) *Billian or Borneo Ironwood* (*Eusideroxylon swageri* T. and B.) is the eastern counterpart of the greenheart so far as use is concerned. It is exported mostly from British North Borneo. The wood is yellow when fresh cut, but on exposure turns to a glossy brown. (3) *Embuia* (species of *Nectandra*) is the timber de luxe of parts of Southern Brazil and because of its great durability is extensively used as a railroad tie. It occurs in the Paraná pine forests of the states of Paraná and Santa Catharina, Brazil.

VI. The Quebracho or Sumac Family (*Anacardaceæ*).—This is the family to which the sumac and poison ivy of our flora belong. The best known member of this family is the tree that produces the mango fruit (*Mangifera indica* L.), a native of the eastern tropics but introduced throughout the western tropics.

1. *Quebracho* (Argentina and Paraguay).—The wood of this tree (*Schinopsis balansæ* Engl.) yields a valuable extract much used for tanning purposes and locally it also furnishes a very durable railroad tie. It is logged mostly in northern Argentina and the value of the exports of wood and tannin extract reach a higher figure perhaps than the value of all the other exported forest products of South America except rubber. The wood of another species (*S. lorentzii* [Griseb.] Engl.), also called *quebracho*, and found in northern Argentina principally, contains tannin, but at the present time it is little used for this purpose. The woods of a number of other South American species of this and other families are called quebracho. These should not be confused with the real quebracho, although some of them do contain tannin.

2. *Gonçalo Alves* (Brazil); *Diomate* (Colombia); *Gateado* (Venezuela); *Urundoy* (Argentina), and other local names for these and other parts of the American tropics. This group of woods comes from several species of the genus *Astronium* which presumably extends from Central America to northern Argentina. It has been introduced in the United States under the name of *king wood*. In color the wood is brownish red with black, or nearly black, streaks. It is used for construction purposes (in Brazil for railroad ties) and as a cabinet and furniture wood.

3. *Espavo* (Panama); *Caracoli* (Colombia and Venezuela); *Mija or Mijagua* (Venezuela).—This is reddish, moderately soft wood, found in northern South America and adjoining regions, and is used locally to some extent as a light construction material. From Panama it has been exported to the United States under the name of *espave mahogany*. It is the product of *Anacardium rhinocarpus* D. C.

VII. The Teak Family (*Verbenaceæ*).—*Teak* (*Tectona grandis* Linn.) has long been known as the best shipbuilding timber in the world. The wood is moderately hard, very durable, strongly scented, dark golden yellow in color, turning brown to almost black with age. It is mainly the product of Burma and India, though there are extensive plantations in Java and smaller ones in other parts of the eastern tropics. In the Philippines, *Molave* (*Vitex paviflora* Juss.) is another member of this family that is locally very much used, especially for shipbuilding and construction work in contact with the ground.

VIII. Miscellaneous Woods.— 1. A group of woods known as *Lepacho* (Argentina), *Ipé* or *Páo d'arco* (Brazil), *Surinam Greenheart* (Guiana), *Araguanay* (Venezuela), *Guayacan* (Colombia, Ecuador and Panama) and many other local names, are of a greenish or brownish yellow color, hard, durable and much used for heavy construction work in contact with the ground. They belong to various species of the genus Tecoma (*Catalpa* or *Bignoneaceæ* family). Some guayacan has been shipped to the United States under the name of Lignum Vitæ. (See below).

2. *Peroba.*—This is the generic common name for a group of rose colored or brownish yellow woods that occupy the most common place in the hardwood markets of Rio de Janeiro and São Paulo (Brazil). They are moderately hard, easily worked, and are used for heavy and light construction work, interior finish and for making furniture. The *peroba rosa* (known as *carreto* in Colombia and Venezuela), and in part the *peroba amarello* (Brazil), are the product of certain species of *Aspidosperma* (*Apocynaceæ*). Much of the *peroba amarello* seems to come from certain species of *Tecoma* of the *Bignoniaceæ*.

3. *West India or Venezuela Boxwood.*— The growing scarcity of the true boxwood (*Buxus sempervirens* L.), valuable for rulers and wood-engraving, has led to the introduction of some tropical woods as substitutes. The chief candidates for these substitutes seem to be the following: (a) *Roble blanco,* a *Tecoma* species (*Bignoniaceæ*) from Venezuela and West Indies; (b) species of *Casearia* (*Flacourtiaceæ*), principally from the Maracaibo region of Venezuela, and certain species of *Aspidosperma* (*Apocynaceæ*) from Venezuela. The last two usually are known under the name of *zapatero.* Certain species of *Aspidosperma* under the name of *piquiá marfim* or *marfim* (marble) are found in southern Brazil, although these seem not to have been exported as boxwood. The woods mentioned above are light yellow in color, fine grained, and hard and compact.

4. *Laurel* (Spanish), *Louro* (Brazil).— Scattered throughout the moist regions of the American tropics, under the above names, are a group of woods belonging to the genus *Cordia* (*Borraginaceæ*). They are brownish in color, strong and easily worked, hence are much used for certain classes of construction work. The woods under these names should not be confused with the members of the *Lauraceæ* family mentioned above.

5. *Balsa wood or cork-wood.*— Scattered throughout the damp American tropics, usually under the name of *balsa,* are a group of very light woods (about eight pounds to the cubic foot) that have recently been much used in the making of buoys for life boats and are now being used for lining refrigerators. They are usually referred to *Ochroma lagopus* Sw. (*Bombacaceæ*), but it appears now that several species of this genus produce this wood.

6. *Kapoc; Cotton tree; Ceiba* (Spanish); *Samaúma* (Brazil).— The *kapoc* of commerce is the cotton from the fruits of a tree (*Ceiba pentandra* Gærtn., family *Bombacaceæ*), and is exported mainly from planted trees in Java, and is used extensively in stuffing mattresses. The tree, however, is a native of the moist American tropics and is one of the largest in the forests. The wood is very soft and at present is very little used.

7. *Ebony.*— The true ebonies of commerce come usually from certain species of the genus *Diospyros,* the persimmon family (*Ebenaceæ*). The trees that produce this wood are found very scattered throughout the tropical forests of both hemispheres. The woods are very hard and dense and generally black or brown streaked with black. The growing scarcity of true ebony has led to the introduction of many substitutes belonging to species of other families.

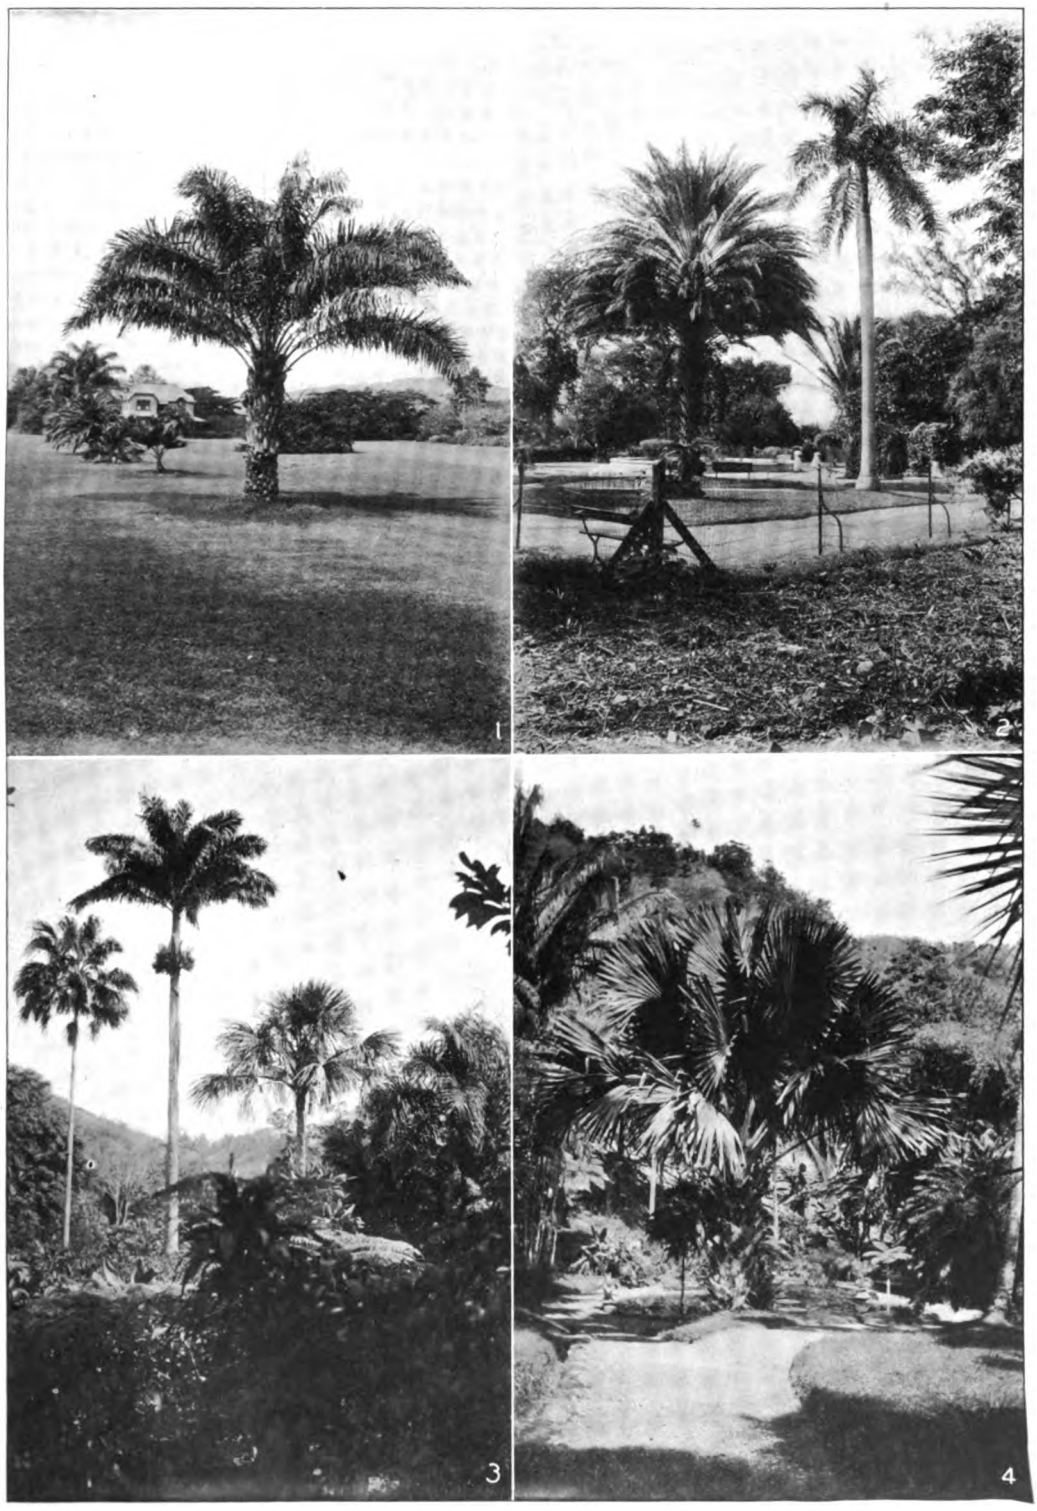
8. *Fustic, Mora* (Latin America).— *Fustic* is the market name of perhaps the most important dyewood of commerce. It is mainly exported from the Caribbean Sea region of the American tropics. It is the product of *Chlorophora tinctoria* L. Gaud. of the family *Moraceæ.* It is used in dyeing shades of yellow, brown, olive and green.

9. *Lignum Vitæ; Guayacan* (Spanish).— This is usually the product of various species of *Guiacum officinale* L. and *Guiacum sanctum* L., although other species of *Guiacum, Bulnesia arborea* Engl. (locally known from Venezuela as *vera*), and *Bulnesia sarmienti* Lorentz (known from Argentina as *palo santo*), furnish some of the wood. They all belong to the family *Zygophyllaceæ.* The wood reaches the markets of the world principally from the West Indies, Northern South America and Central America. The wood is much used in certain parts of shipbuilding especially in stern bushings and for bowling balls, bed castors, pulleys, etc. It is extremely hard and heavy and oily.

IX. The Mangrove Family (*Rhizophoraceæ*).— The mangrove forests of the tidal swamps of tropical regions, composed mostly of species of the above family, are literally forests of the sea. Although found best developed in the estuaries of large rivers in the eastern tropics, they are also present in the western hemisphere. Here one species (*Rhizophora mangle* L.) is found, while in the Eastern tropics a number of species of this genus, and of the genera *Bruguiera* and *Ceriops,* form the main composition of the forests. While there are many local names for the different species in the eastern hemisphere, the general local name in the Philippines and Spanish America is *mangle,* and in Brazil, *mangue.* In proportion to the area they cover they are locally the most valuable of all the forests for they are the main source of firewood and tannin extracts. The latter, especially from Borneo, is exported in considerable quantities.

X. The Pine Family (*Pinaceæ*).— While the woods of the pine family are marketed mainly from temperate zones, mostly the North Temperate, yet the highlands of the tropics and subtropics contain a number of "pines" that are used locally and are coming to be exported to some extent. Many of the true pines (*Pinus*) and other genera of the western part of the United States extend into Mexico and in some parts form extensive forests. Pine in merchantable quantities is also found in parts of the West Indies, and in Guatemala and Honduras of Central America. Preparations are already being made to exploit these forests.

TREES, TROPICAL



1 Oil Palm (Elæis guineensis)
3 a. Livistona subglobosa. b. Euterpe oleracæa. c. Mauritia flexuosa

2 a. Date Palm (Phœnix dactylifera). b. Cabbage Palm (Oreodoxa oleracea)
4 Indian Fan Palm (Corypha elata)

India, Burma and the Philippines contain true pines that are used locally. The lower slopes of the Himalayas in India also contain other genera of the family that are quite extensively utilized. In the semi-tropical regions of the Brazilian states of Paraná, Santa Catharina and Rio Grande del Sul, and in the state of Missiones (Argentina), occur very large areas of the *Paraná pine* (*Araucaria braziliana* A. Rich.). There forests contain about 200 billion board feet of standing timber and are playing an important rôle in furnishing softwood lumber to the adjoining industrial regions of southern Brazil, Argentina and Uruguay.

XI. Bamboos (*Graminæa*).— The bamboos and their allies are the grass trees of the tropics. They furnish cheap wood for the poorer classes for construction purposes and for almost every use to which wood can be put. Bamboos are more abundant in the eastern than in the western tropics where, besides occurring as constituent parts of some wild forests, they are extensively planted, also to some extent throughout the western tropics. The construction bamboos belong principally to certain species of the genera *Bambusa, Arundinaria* and *Dendrocalamus*. While wild bamboos occur in the western tropics and are cultivated to some extent, they do not play so important a part in the life of the people. In certain parts allies of the bamboos or canes take their place. These are the cana brava (*Gynerium sagittatum* [Aubl.] Beauv.), and species of *Guada* known locally in the Amazon as *taboca* and in Ecuador under the market name of *Guayaquil cane*. This is rather extensively exported as a construction wood to the dry treeless coastal regions of Peru and Northern Chile.

XII. Palms (*Palmæ*).— In regions where bamboos are not abundant palms largely take their place as construction timbers. Besides they furnish a large number of minor forest products. Certain palms produce food, in others the nuts produce valuable oils, and some yield wax, and from others vegetable ivory is obtained. Besides the cocoanut and the date palms which are really not forest products, the following are mentioned because they produce products that are extensively exported:

1. *The ivory nut palm or vegetable ivory.* — The ivory nut is the product of a number of species of the genus *Phytelephas*. It is found in portions of Ecuador, Colombia and the Amazon. At present it is one of the principal exports of Ecuador and this country is the chief source of the nuts. Ivory nuts are principally used for buttons, but many small objects like checkers, chess, etc., are made from it.

2. *Rattans.*— The rattans of commerce are the product of several species of the genus *Calamus* and related genera. They are climbing palms, in some cases they reach the great length of 400 or more feet, and clamber from tree to tree in the forests. They are confined to the eastern tropics. They furnish the main cordage of the countries in which they grow. When exported and in the round they are used for canes, umbrella handles and for making chairs; and "split" rattans find their greatest use for seats and backs of chairs.

3. *The Oil Palm.*— The nut of this palm is extensively exported from West Africa for the valuable oil it contains. It is also found in Brazil where it was introduced from Africa. Here it is used locally only. It is the product of *Elæris guieensis* Jacq.

4. *Wax Palm.*— This palm yields a wax that comes from scales on the underside of the leaf. The palm is *Copernicia cerifera* L. and is exported mainly from northeastern Brazil.

5. *The Panama Hat Palm.*— This belongs to the *Cyclanthaceæ*, a family closely related to the palms. The species that furnishes the "straw" for Panama hats is *Corludovica palmata* R. and P. The making of Panama hats is a very important industry in Ecuador, and neighboring parts of Peru and Colombia.

XIII. Rubber, Guttapercha, Chicle.— The trees and other plants that produce the rubber of commerce are found in many parts of the tropical world. The principal one of these is *Hevea braziliensis* Muell. Arg. (*Euphorbiaceæ*), a tall tree, native of the vast Amazon region. Formerly most of the rubber of commerce was collected from this region. While the supply from the Amazon valley has not decreased, the increasing demand for rubber has been met by the extensive rubber plantation of the Malay Peninsula and neighboring regions, principally Ceylon, Sumatra, Burma and Borneo. The eastern tropics now produces fully 80 per cent of the world's supply of crude rubber. The commercial name of rubber from *Hevea braziliensis* and certain other species is *Pará rubber*. It has the local name of *seringa*. *Ceara rubber* (*Manihot glaziovii* Müll. Arg. and other species) locally known as *Maniçoba*, belongs to the same family as the Pará rubber. It comes from the dry regions of northeastern Brazil and is cultivated to some extent in other parts of the tropics. Next to *Pará rubber* in importance is the so-called Castilloa rubber, the product of *Castilla elastica* Cerv. and other species of this genus and belongs to the family *Moraceæ*. It is a native of tropical America from southern Mexico to the Amazon region. In Brazil it is known as *caucho* in distinction from the *seringa* (Pará rubber). This rubber tree has been cultivated extensively.

The *Mangabeira* rubber, mainly the product of *Hancornia speciosa* Gom. belongs to the family *Apocynaceæ*. It is found throughout the region from the territory of Acre, Brazil, to southern Paraná, Brazil, and in adjoining regions of other countries. It is cultivated to some extent but as yet the cultivated rubber is not commercially important. To this family also belong the African wild rubbers, principally species of the genera *Landolphia* and *Kickxia*.

Gutta percha is not a rubber, for it is plastic rather than elastic. It comes from trees that belong to the family *Sapotaceæ*, mostly certain species of the genera *Payena* and *Palaquium* that are found only in the Indo-Malay region. In the western tropics *balata*, mostly the product of *Mimusops balata* Gærtner., is the nearest to gutta percha. It comes mainly from the Guianas and Venezuela.

Chicle is the source of the chewing gum of commerce. It is the gum of a tree known under common names of *sapodilla* or *nispero* and other local names. This is *Achras zapota* L. The *chicle* of commerce comes mostly from southern Mexico where the tree is native. It is planted, however, in other tropical countries.

H. N. WHITFORD,
Yale School of Forestry.

TROPICAL FORESTS. The beauty of a tropical forest is greatly overestimated by dwellers in temperate climes. The testimony of nearly all travelers to the tropics is to the effect that nowhere did they see such an expanse of flowers and charming forests as those they had left, and they all complain of the monotonous greenness of the trees, which have never to prepare for winter. Where the trees are most immense and crowded, as in the Amazon district, and in the East Indies, the forest is lonely and silent, shadowy and sombre in the subdued light. The trunks rise without branches for many feet, tied together with creepers and lianes, in an indescribable confusion of festoons and ropes and cables, reaching from tree to tree, and to the ground; some flat, some twisted either around each other or smothering a tree; some limp and swaying, others drawn taut like the stays of a ship's mast. Many of them are climbing palms (*Calamus*) and many are armed with cruel fishhook-like thorns. The lianes, and the trees themselves, support myriads of small epiphytic or parasitic plants, ferns, fungi and countless other species. Overhead the forest is roofed by the tops of the trees and of the creepers; the foliage is sharply defined against the sky, even the finely-cut delicate leaves of the great leguminous trees characteristic of these forests. Nearly all the flowers of the deep forests are confined to this upper stratum, where the sun's rays can reach them, and they are not always easily seen, being often green or white, and inconspicuous amid the verdure. The flowers of the most tropical trees, moreover, are, even when brilliant, very fugacious; one reads of people walking through the maple leaves petals of a day, as through the maple leaves in autumn. The forest trees, however, are very prolific, and many of them bear bud, blossom, and unripe and mature fruit at the same time. The forest giants in some instances have protected themselves against the dangers of the great height and top-heaviness. Tapangs and figs have great buttresses like undulating wooden walls, others, as the screw-pines and the mangroves, perch on aerial roots, sent down from trunk and branches. The last are found along sea-shores, stepping far out into the water, backed by the screw-pines and nipa-palms and presenting an almost impenetrable front, woven into a thicket by interweaving creepers, interminably long and even thorny. It is at such edges of the forest, in clearings and along roadsides, that one sees the imagined beauty of the tropics. There the under-shrubs have a chance to grow and bloom, interspersed with graceful tree ferns and waving palms. The creepers and tree-branches descend and hang waving and blossomladen over the masses of ferns and ground plants; and there the brilliant blossom of orchid and parasite and epiphyte are visible.

African forests are often like those of temperate zones, with open glades and clumps of trees. One can hardly call the oases of palms in the deserts, forests. In Abyssinia the country has been likened to the Scotch Highlands.

It is Australia, however, which has the most peculiar tropical forest, for in spite of the fact that her gum trees are the tallest trees in the world, it is a shadeless land. So burning are the sun's rays, that the leaves of the predominating eucalyptus are so disposed as to present always their edge to the sky; the acacias have delicate compound leaves, the ti-shrub has reduced its foliage to mere needles, and the weird she-oak has dispensed with leaves altogether, string-like branchlets taking their place. The first impression of an inland Australian forest is one of monotony in color and appearance, and of burning heat and desolation heightened by the flapping strips of the bark of the gum-trees, which is cast away as northern trees shed their leaves.

TROPICS. (1) *In astronomy,* two circles on the celestial sphere, whose distances from the equator are each equal to the obliquity of the ecliptic, or 23½° nearly. The northern one touches the ecliptic at the sign Cancer, and is thence called the Tropic of Cancer, the southern one being for a similar reason called the Tropic of Capricon. The sun's annual path in the heavens is bounded by these two circles, and they are called tropics, because when the sun, in his journey northward or southward, reaches either of them, it reverses its polar movement, and turns back, or travels in an opposite direction in regard to north and south. (2) *In geography,* the tropics are two parallels of latitude, each at the same distance from the terrestrial equator, i.e., 23° 27′. The one north of the equator is called the Tropic of Cancer, and that south of the equator the Tropic of Capricorn. Over these circles the sun is vertical when farthest north or farthest south, that is, at the solstices, and they include between them that portion of the globe called the torrid zone, or the "tropics," or tropical regions, a zone almost 47 degrees wide, having the equator for its central line. The Tropic of Cancer passes through the centre of Mexico, just misses the northern point of Cuba, next invades the Sahara desert, crossing the Nile at Dendur, north of the Nubian desert, cuts Arabia centrally, then passes through northern India, China at Canton and across the island of Formosa to the Pacific Ocean, passing a little north of Hawaii. The Tropic of Capricon crosses Chile, Argentina, Paraguay and southern Brazil, strikes Africa just south of Walfish Bay, in what used to be German territory, cuts through the northern Transvaal and Portuguese East Africa to Inhambane Bay; it then passes through southern Madagascar and divides Australia.

TROPINE, $C_8H_{15}NO$, an organic basic substance obtained by action of heat and baryta on

the alkaloid atropine. Colorless crystals soluble in water and alcohol.

TROPISMS, influences exerted by their environment upon plants or animals leading to involuntary actions, or to mechanical alterations of posture, growth, etc. Such influences are exercised by chemical agents, by the earth, water, sunlight, heat, electricity, etc. See CHEMOTROPISM; GEOTROPISM; HELIOTROPISM; THERMOTROPISM, etc.

TROPPAU, trŏp'pow, Austria, capital of Silesia, on the Oppa, 78 miles northeast of Brünn. It is well built and consists of an inner town, with pleasure-grounds on the site of the former fortifications and of three suburbs. Handsome public buildings include several fine churches, an upper gymnasium, a museum, a library of 35,000 volumes, an upper real-school, and other educational institutions. The chief manufactures are woolen and linen cloth, beet-root sugar, beer, liquors, paper. A congress of sovereigns was held here in 1820, occasioned by the revolutions of Spain, Portugal and Naples. Pop. about 32,300.

TROSSACHS, trŏs'ąks, (bristles), Scotland, a romantic defile forming an approach to the Western Highlands, in Perthshire, about eight miles west of Callander. It extends for about a mile between Lochs Ackray and Katrine, winding between Ben A'an on the north and Ben Venue on the south, and confined by lofty rugged precipices covered to their summits with birch, pine and other trees. It is a favorite region for tourists and is in the locality where lived Scott's 'Lady of the Lake.'

TROTTER, Newbold Hough, American artist: b. Philadelphia, Pa., 4 Jan. 1827; d. Atlantic City, N. J., 21 Feb. 1898. He was graduated at Haverford College in 1845; engaged in business till 1858, when he turned his attention to the fine arts. When the Civil War broke out he joined the Germantown Home Guards and took part in the battle of Antietam. After the war he was appointed by the United States government to paint all the mammalia of North America in a series of volumes to be issued by the government. His best known pictures include 'Grizzly Bears'; 'Wounded Buffaloes'; 'The Last Stand' and 'Indian Encampment' and three paintings representing the progress of the means of travel in Pennsylvania during 50 years.

TROTTING. See HORSE-RACING; SPORTS: THEIR DEVELOPMENT, SPEEDS AND RECORDS.

TROTZKY, Leon (pseudonym for LEON BRONSTEIN), Russian Socialist: b. Odessa, 1879. In 1900 he was imprisoned at Odessa for participating in a revolutionary labor movement. Since early youth Trotzky has been an ardent advocate of the cause of the Social-Democratic Party, and one of the ablest agitators and orators who have written and spoken in its defense. He had traveled all over Europe before the outbreak of the War in 1914 (for instance, the social complications resulting from the Balkan Wars led him to tour the Balkans in 1912, for the purpose of social study). The outbreak of the war found him in Vienna, which he left on the same day for Switzerland, where he spent a number of months, engaged in Socialistic agitation. He wrote here an interesting pamphlet, in Russian, of which German and English translations appeared later (one under the title 'The Bolsheviki and World Peace'; New York 1918), attacking the European Socialistic parties for supporting their governments in the war; in Germany he was punished by a sentence to six months' imprisonment, pronounced in his absence. In Paris, where he next settled (1915), he edited, for the Russian colony, a Socialist weekly, *Nashe Slóvo*, but his merciless and uncompromising propaganda soon led to his exile from France to Spain (this period is interestingly covered in his 'Chapters from My Diary,' written in Russian for *Novy Mir;* English trans. in *The Revolutionary Age,* Boston 1918). From Spain he sailed, by way of Cuba, to New York, where he arrived 14 Jan. 1917. During his short stay in America he worked for several weeks as an editor on the Russian Socialist daily *Novy Mir,* devoting his evenings to lectures in Russian and German (he knows very little English and is not so good a linguist as Lenine) to New York branches of the Socialist party. Immediately after receiving news of the outbreak of the Russian Revolution, he sailed from New York for Europe on the Norwegian steamer *Christianiafjord* 28 March, but was removed 3 April from the ship at Halifax by British authorities and interned in a concentration camp at Amherst, from which he and his family were only released a month later, when they were permitted to continue their journey on the Danish steamer *Hellig Olav.* Trotzky's own description of these experiences will be found in an article 'In British Captivity,' published in *The Class Struggle* (New York 1918). After his arrival in Petrograd, Trotzky at once became one of the intellectual leaders of the Bolshevik section of the Social-Democratic party, although he had not, like Lenine, been identified with this movement from its inception in 1903. In June 1917 he established a weekly propaganda paper at Petrograd, called *Vperiod* (*Forward*), in which a number of articles and speeches in his brilliant and inspiring manner appeared. After the Bolshevik *coup d' état* of 6 Nov. 1917, Trotzky became Minister (People's Commissaire) for Foreign Affairs, while Lenine (q.v.) became Premier; later the Foreign Affairs portfolio went to Chicherin, while Trotzky headed the Department of the Army and Navy. He was one of the Russian delegates to the Brest-Litovsk conference and signed the Treaty of Brest-Litovsk with the delegates of the Central Powers on 9 Feb. 1918. A full account of his participation in the Bolshevist coup, as well as in the peace negotiations, will be found in his book 'From October 1917 to Brest-Litovsk' (New York 1919). In September 1918 reports of alleged connection between Trotzky and the German government were circulated in the American press (on these, see LENINE, NIKOLAI). Rumors of large armies raised and organized by Trotzky, possessing immense military resources, and intended to invade Germany in the support of the revolution in that country (which opened, largely as a result of Russian propaganda, in November 1918), persisted for many months in 1918–19. Consult Williams, A. R., 'The Bolsheviks and the Soviets' (New York 1918).

JACOB WITTMER HARTMANN.

TROUBADOURS, troo'ba-doorz, **The.** See PROVENÇAL LITERATURE.

TROUBETZKOY, troo-bĕts'koi, **Amélie Rives,** PRINCESS, American novelist: b. Richmond, Va., 23 Aug. 1863. She was married to John Armstrong Chanler in 1888, but secured a divorce from him on account of incompatibility, and in 1896 was married to a Russian artist, Prince Pierre Troubetzkoy. Among her works are 'The Quick or the Dead?' (1888); 'Virginia of Virginia' (1888); 'The Witness of the Sun' (1889); 'Barbara Dering' (1892); 'Tanis, the Sang-Digger' (1893); 'The Mocking of the Gods' (1902); 'Seléné' (1905); 'Augustine the Man' (1906).

TROUBETZKOY, PRINCE **Paul,** Russian sculptor: b. Intra, Italy, 1866. The son of a Russian nobleman, he worked by himself, after study under Bazzaro, and won recognition with his 'Indian Scout' in 1894. Three years later he removed to Moscow, where he was appointed professor of sculpture at the academy and from this date he did much vigorous work. Since 1905 he has lived in Paris and specimens of his art are found in many European galleries. Among his later works are the equestrian monument to Alexander III (1909, Petrograd) and 'The Daughter of Prince Scipione Borghese on Horseback' (1908). He has received numerous gold medals for his work.

TROUESSART, Edouard Louis, French zoologist: b. at Angers, 1842. He took the degree of M.D. at Paris in 1870 and served as surgeon in the French army, becoming, finally, professor of zoology in the Museum of Natural History in Paris. His publications are numerous and in 1895 he was laureate of the Société entomologique.

TROUP, troop, **George McIntosh,** American statesman: b. on the Tombigbee River, then in the Territory of Georgia, 1780; d. Laurens County, Ga., 3 May 1856. He was graduated at Princeton in 1797, was admitted soon after to the bar, and at 21 was elected a member of the State legislature. He was a representative in Congress from Georgia 1807–15, and in 1816 was elected a United States senator. From 1823 to 1827 he was governor of Georgia, and in 1829 was a second time elected to the National Senate. He was a man of great integrity, an impassioned speaker, and one of the most earnest and able of the advocates of State rights and State sovereignty.

TROUT, any of the various smaller species of fresh-water fishes of the family *Salmonidæ* (q.v.); especially a "charr" of the genus *Salvelinus,* and specifically the speckled or brook trout of eastern North America (*S. fontinalis*). The name comes originally from the European brown trout (*S. faris*). The distinction between the closely related salmon-trouts (q.v.) and the true trouts, or charrs, is most surely found in the character of the dentition. Harris has explained the difference as follows:

"Put your finger in the mouth of your capture, and if you find the vomer, a bone situated on the front part of the roof of the mouth, flat, with teeth on its body, and behind these an irregular single or double series of teeth, you hold in your hand a salmon-trout. If you find the vomer much depressed, convex and shaped like a boat, with teeth on the head of the bone, and none on its shaft, you have a charr under inspection."

All of the American charrs, except the Dolly Varden and three of the Arctic species, are natives of the waters east of the Mississippi, the common brook or speckled trout being the most widely distributed. The last species may be known at sight by the worm-like markings on the back, red spots on the sides, the large mouths, blunt snouts and dark mottlings on their dorsal and tail fins. It is the most beautiful of all the charrs by reason, as Harris writes, of the mantle of rose and violet which it wears, the mellow diffusion of which suggests and justifies the descriptive phrase so often applied to it by anglers — "the bloom of the trout." It is to be found in the streams flowing north into the Arctic Ocean, as far west as Victoria Land; ranging north and westward to the tributaries of the Great Lakes, and as far south as the southern spur of the Georgia Alleghanies. It also occurs near the sources of some of the rivers flowing into the Mississippi River and the Gulf of Mexico. The habits of trout are as various as the streams in which they dwell and the moods of the weather, and anglers find constant novelty in studying them in an effort to overcome their devious and cunning ways. Their breeding is after the general method of their race, but they never go down into salt water. They mate late in summer, and the male keeps off intruders. The female uses her tail in making the nest, whipping the gravel until a hole is made about two inches deep, and then cleans the bottom for a foot or more around the hole. When she is ready to spawn the male knows it and approaches her. The ova are then dropped and the milt is deposited upon the eggs, the male being within a few inches of his consort. This occurs in northern New England in November or early December; farther north at early dates. But many of the eggs fail to become fertilized, dropping down stream on the current; they are devoured by minnows or other fish who are lurking in the vicinity. Probably not 5 per cent of the ova dropped on natural spawning beds ever mature, while of those raised by the improved methods of the fish culturist fully 80 to 90 per cent come to maturity in the hatching ponds. Unfortunately those raised by the artificial process are generally placed, when fingerlings, in streams abounding with their natural enemies, and but a small percentage of these innocents become yearlings, at which age they are able to take care of themselves.

The charrs are also represented in Maine and New Hampshire by the Sunapee trout (*Salvelinus alpinus aureolus*), which is classified by ichthyologists as a local variety of the European charr or saibling (*S. alpinus*), peculiar in its local coloration and other characteristics. It is "brownish, sides silver-gray, with small orange spots on sides above and below lateral line; caudal grayish; belly orange; anal orange, edged before with white; ventrals orange with a white band on outer rays; no mottlings anywhere." This beautiful charr is as good to eat as it is good to catch. It reaches a weight of 10 pounds and rises freely to the fly in May and early June, after which, as the water grows warmer, it settles into deeper water, and in July and August takes a live

minnow and fights finely at a depth of 50 to 60 feet. It is connected with its European type by the arctic trout, a variety (*arcturus*) of the Arctic Coast north of Hudson Bay and variety *stagnalis* of the rivers of Greenland and Boothia.

The quasky, or blueback trout (*S. oquassa*), is the smallest and one of the handsomest of the charr trouts. It never exceeds 12 inches in length and is dark blue, the red spots small and round and usually confined to the sides of the body. Its habitat is confined to Moosehlucmaguntic Lake, of the Rangeley system, in Maine, although Professor Merriam states that identical fish have been caught in the lower Saint Lawrence River weighing six or seven pounds. The blueback lies concealed in the deep water during the greater part of the year, but about 10 October comes near the shore and ascends in shoals the Kennebago River for the purpose of spawning. Half a mile above its mouth the Kennebago receives the outlet of Lake Oquassa; the trout then leaves the Kennebago to the left and runs toward Oquassa Lake, when its voyage comes to an end. About the middle of November it goes back to Moosehlucmaguntic Lake and is seen no more until October of the next year. The blueback resembles the Sunapee trout more than any other of the charr species, yet differs from it in size, spawning habits and markings of the young. Varieties of it are known in certain lakes in northern Quebec and in the rivers of the Arctic Coast. The only trout native to the waters west of the Rocky Mountains is the red-spotted, bull or Dolly Varden (*S. malma*). It is found in the streams east and west of the Cascade Range from the upper Sacramento to Montana. It is a gaudy and large species, and good, but is not the equal of its Eastern congeners in game qualities.

Trout are justly regarded as the most interesting of all the smaller fishes that attract the angler. They are taken with the garden worm, the grub, the live minnow and the artificial fly by the method explained in the article ANGLING (q.v.). For artificial cultivation, see FISH-CULTURE.

Bibliography.— Goode, 'American Fishes' (New York 1888); Jordan, D. S., 'Fishes' (New York 1908); Jordan and Evermann, 'American Food and Game Fishes' (new ed., New York 1914); McCarthy, 'Familiar Fish' (New York 1900); Phillips, E., 'Trout in Lakes and Reservoirs: A Practical Guide to Managing, Stocking and Fishing' (New York 1914); Rhead, L., 'American Trout Stream Insects' (New York 1916); Sage and Cheney, 'Salmon Trout' (New York 1902); Stone, 'Domesticated Trout' (Charleston, N. H., 1877).

TROUVÈRE, troo-vâr', a member of the class of ancient poets of northern France, corresponding to the troubadour of Provence. Their productions partake of a narrative or epic character and thus contrast broadly with the lyrical, amatory and more polished effusions of their southern rivals.

TROUVILLE, troo-vēl, France, a fashionable watering-place on the English Channel, in the department of Calvados, situated at the foot of a hill on the right bank of the Touques at its mouth, near the mouth of the Seine, 10 miles south of Havre. It has a harbor, comprising an inner and an outer basin, and a splendid beach. The Casino or Salon offers all the attractions usually found in such institutions. The season is at its height in August. Boat-building and fishing are the only real industries. Pop. about 6,901.

TROVATORE, Il. Verdi's opera of 'The Trouhadour,' first produced in New York 2 May 1855, but given in Rome two years earlier. It is known the world over for its wonderful melody.

TROVER, *in law,* an action to recover the value of goods unlawfully converted by another. Originally this was an action on the case for damages against one who had found goods belonging to another and refused to give them up on demand of their owner.

TROWARD, Thomas, English New Thought apostle: b. Belgaum, India, 1844; d. 1916. During his youth and young manhood in India he imbibed the principles of Eastern philosophies and about 1904 he retired from the position of division judge which he held and came to Great Britain, lecturing and writing on the application of the underlying spiritual principles found in all religions to the active life of to-day. Though he is classed as a mental scientist and New Thought advocate he was really a sincere, educated Englishman who devoted his later days to trying to inform the Western peoples what they had to learn from Eastern philosophies. He published 'Lectures on Mental Science' (Edinburgh 1906); 'Bible Mystery and Bible Meaning' (1907); 'Dove Lectures' (1909); 'The Creative Process' (1911), etc.

TROWBRIDGE, trō'brĭj, **Edmund,** American jurist: b. Newton, Mass., 1709; d. Cambridge, Mass., 2 April 1792. He was graduated at Harvard in 1728 and for some time bore the name of Goff, which was that of an uncle. He became attorney-general for Massachusetts (1749) and was elevated to the Supreme Court (1767) where he presided over the trial of Capt. Thomas Preston and his men for firing on the people in Boston (5 March 1770). In 1772 he resigned. As executor of John Alfred, a wealthy Boston merchant, he founded at Harvard the Alfred professorships of natural religion, moral philosophy and civil polity.

TROWBRIDGE, John, American scientist: b. Boston, Mass., 5 Aug. 1843. He was graduated from the Lawrence Scientific School, Harvard University, in 1866 and served as instructor there, 1866–69. He was assistant professor of physics at the Massachusetts Institute of Technology in 1869–70 and filled the same position in Harvard, 1871–81. He was professor of experimental physics at Harvard, 1880–88 and in the year last named became Rumford professor of applied science there and in 1884 was made director of the Jefferson Physical Laboratory at the same institution. In 1878 he was elected a member of the National Academy of Sciences and later was vice-president of the American Academy of Arts and Sciences. He has published 'The New Physics' (1884); 'What is Electricity?' (1896); 'The Resolute Mr. Pansy' (1897); 'Three Boys on an Electric Boat' (1894); 'The Electrical Boy' (1891); 'Philip's Experiments, or Physical Science at

Home' (1898) and many papers on physics and more especially on electricity.

TROWBRIDGE, John Townsend, American author: b. Ogden, Monroe County, N. Y., 18 Sept. 1827; d. 12 Feb. 1916. He attended a district school and by doing farm chores managed to obtain sufficient funds to attend a classical school at Lockport, N. Y., for one term. Then he went to Illinois for a year, teaching school in the winter and working as a farmhand in summer. Returning to Lockport he taught school for a few months and then decided to devote himself to literature, for which he early had evinced a fondness. At 19 he went to New York City. His literary aspirations found no encouragement, and after a year of futile effort he removed to Boston. There he soon became widely known as a writer of stories and sketches under the pen name of Paul Creyton. In his first book, 'Father Brighthopes' (1853), Mr. Trowbridge caught the fancy of the boys of that day, and with a long series of volumes he held juvenile interest unabated through succeeding generations. These included 'The Drummer Boy' (1863); 'Cudjo's Cave' (1863); 'The Three Scouts' (1864); 'Neighbors' Wives' (1867); 'Coupon Bonds and Other Stories' (1872); 'The Silver Medal' (1908); 'A Pair of Madcaps' (1909); 'The Jack Hazard Series'; 'Toby Trafford Series'; 'Start in Life Series' and 'The Tide Mill Series.' For many years he edited *Our Young Folks,* which numbered among its contributors Dickens, Whittier, Mayne Reid, Harriet Beecher Stowe and Louisa M. Alcott. Although his verse does not show the enduring excellence that marked his boys' books, 'Darius Green and His Flying Machine' (1870) proved him to have been unconsciously a prophet with honor. Consult his autobiography, 'My Own Story' (1903).

TROWBRIDGE, Samuel Breck Parkman, American architect: b. New York, 20 May 1862. He was graduated at Trinity College, Hartford (1883), at Columbia School of Architecture (1886) and then studied abroad. After graduation from the School of Architecture he was sent by the Archæological Institute to superintend the erection of the American School of Classical Studies at Athens, Greece. Later he became a member of distinguished New York firms of architects and established a high standard in his profession. He was appointed by President Roosevelt as chairman of the National Council of Fine Arts. He is a member of many foreign societies and was appointed a Chevalier of the Legion of Honor (1910) and elected to the National Institute of Arts and Letters (1915).

TROWBRIDGE, William Petit, American engineer: b. in Oakland County, Mich., 25 May 1828; d. New Haven, Conn., 12 Aug. 1892. He was graduated at West Point in 1848, served there during the last year of his cadetship as assistant professor in chemistry, later as assistant in the astronomical observatory, and in 1851 was assigned to the coast survey. His work on the Pacific Coast in 1853 embraced a series of magnetic and tidal observations covering a distance of over 1,300 miles, from San Diego to Puget Sound. In 1860, at Key West, Fla., he superintended the erection of the first permanent self-registering magnetic observatory in the United States. After the outbreak of the Civil War he furnished minute descriptions of the rivers, harbors and inlets of the Southern coast to the War Department, and later was stationed at New York, where he superintended the accumulation and transmission of field-supplies. Besides these duties he superintended the construction of fortifications at Willett's Point and at Governor's Island, and the repairs of Fort Schuyler. In 1870 he became professor of mechanical engineering in the Sheffield Scientific School at Yale, and later held a professorship in the Columbia School of Mines, and at both institutions rendered an efficient service in the establishment and development of new courses of instruction. To him belongs the credit for the design of the first cantilever bridge, details of which are given in his work, 'Proposed Plan for Building a Bridge across the East River to Blackwell's Island' (1869). A company was formed to carry out the scheme, but the financial crisis of 1873 put an end to the plan. He was the inventor of a coil-boiler, utilizing forced circulation of water, a principle that later came into use. His publications include 'Heat as a Source of Power' (1874) and 'Turbine Wheels' (1879).

TROY, troi, or **ILIUM,** a famous ancient city in the northwestern part of Asia Minor, the capital of the Troad, a region lying on the coast of the Ægean Sea, at the entrance to the Hellespont (Dardanelles). The fame of Troy rests upon the two Homeric epics, the Iliad and the Odyssey (see HOMER), which, incidentally to their main themes, give an account of the long war in which the city was finally destroyed. The date of the latter event is generally placed at 1184 B.C. The cause of the war was the abduction of Helen, the wife of King Menelaus of Sparta, by Paris, son of the Trojan king, Priam. Almost all the states of Greece proper united to avenge the insult, and, under the leadership of Agamemnon, king of Mycenæ, landed on the Trojan coast with a large army. After besieging the city in vain for 10 years, they finally took it by a stratagem. They placed outside the walls a large wooden horse in whose interior a number of Greek heroes were concealed, and the rest of the army then retired to the ships as if they had given up the siege. The Trojans in exultation dragged the horse within the walls, and during the night the Greeks came forth and were joined by the main army which had returned from the ships. The city was now given over to fire, plunder and massacre. Among those who escaped was Æneas, who reached Italy, and, according to the legend, was the ancestor of the first Roman kings. The Homeric legend of Troy is believed by modern scholars to be woven around a nucleus of fact. About the 6th century B.C. a new Troy, *Ilium Novum,* was founded on what has ever since been believed to be the site of the Homeric city. The place is now called Hissarlik, and lies a few miles from the southwestern entrance to the Dardanelles. Here Dr. Schliemann began excavations in 1871 and again in 1890, and his researches prove that the site has been occupied successively by seven cities. The second of these from the bottom bears marks of having been destroyed by a conflagration. Within its walls were found the ruins of a palace, and a number of gold and silver ornaments. Dr. Schliemann

considered this second city to be the city of Priam and the Homeric legend, but later excavations have shown that only the sixth (the fourth from the top, later discoveries having increased the total number to nine) city can be referred to the period described in Homer. Of this city nothing remains except portions of the colossal and well-built outer walls. Consult Schliemann, 'Trojanische Altertümer,' 'Ilios,' 'Troja'; Schuchardt, 'Schliemann's Ausgrabungen'; Schmidt, 'Schliemann's Sammlung trojanischer Altertümer.'

TROY, Ala., city, county-seat of Pike County, on the Central of Georgia and the Alabama Midland railroads, about 50 miles south by east of Montgomery. It is in an agricultural region in which cotton is one of the principal products. It has been incorporated since 1843. Its industries are connected chiefly with the cultivation and marketing of cotton. The educational institutions are Troy Industrial Academy for colored pupils and public schools. There are two private banks. Pop. 6,000.

TROY, Mo., city, county-seat of Lincoln County, on the Saint Louis and Hannibal Railroad, about 50 miles northwest of Saint Louis. It is in a region rich in deposits of glass sand, iron ore and coal, and surrounded by fertile agricultural lands. The chief manufacturing establishments are flour mills, butter and cheese factories and tobacco factories. The shipments are chiefly farm and dairy products, tobacco products and livestock. There is one high school, public elementary schools and a library. There are two State banks. Pop. about 1,120.

TROY, N. Y., city, county-seat of Rensselaer County, on the east bank of the Hudson, 150 miles north of New York, 191 miles west of Boston, 235 miles south of Montreal, Canada, and 296 miles east of Buffalo. It is at the head of tidewater navigation on the Hudson River, and the New York State Barge Canal system has its main outlet opposite the city. Through the State Barge Canal, Troy has connection with the Great Lakes and the Northwest, while the Champlain branch of the canal gives an opening to Canadian territory. Steamers and barges ply regularly between Troy and New York and the intervening cities. The United States has spent large sums of money in improving the channel in the river so the larger vessels for the new canal system have no difficulty in reaching the canal. The steam railroads operating in Troy are the New York Central, the Delaware and Hudson, the Boston and Maine and the Rutland. There are also long-distance trolley roads, some of them maintaining freight service, that extend through the Hudson Valley to Lake George on the north; through the Mohawk Valley on the west; south through the Hudson Valley and eastward to the manufacturing villages along the Wynantskill Creek, a distance of 12 miles. These transportation facilities give Troy great advantages as a manufacturing and distributing point, so there are built up opposite the city, not half a mile from its borders, but not included in its population, the cities of Watervliet and Cohoes and the villages of Waterford and Green Island. With those places Troy is connected by bridges over the Hudson River, there being four. There is a modern steel bridge across the Hudson at Congress street, which carries foot passengers, vehicles and street cars. Built as a toll bridge, the State of New York acquired it under condemnation proceedings.

Trade and Manufactures.— Troy ranks ninth in population among the cities of the State, but fifth in industries. The chief manufactures are collars and cuffs — about 90 per cent of all the collars and cuffs made in the United States are made in Troy. So great has this industry become in this city that special machinery has been invented for it and is manufactured here. It has an extensive system of laundries, and for this industry special machinery has also been invented and is manufactured in this city. It is noted for its high grade of merchant iron; its valves and hydrants (valves of 96 inches inside diameter are now made here). Other manufactures are stoves, knit goods, paper, cars, electrical machinery, mechanical and engineering instruments, bells, paints, clay products, floor cloths, brushes, tobacco, cigars, carriages, scales, currency ink, horseshoes, ranges, hydrover tractors, blowers and fans, fishline, twine, shirtwaists, cotton waste, knit goods, shirts, thermometers, stamped tinware, metal stove-front bars, marine engines, beaded bags, anchor chains, etc. The famous machine-made horseshoe invented by Henry Burden is manufactured here. He also made the largest over-shot water-wheel yet made in America. It is 60 feet in diameter. The guns for coast defense of the United States are made at the government arsenal at Watervliet, opposite Troy. Troy and its environs are now undergoing a great industrial expansion, the first definite movement of this sort in the recent history of the city. During the war, the Watervliet arsenal was enlarged until it became the largest government arsenal in the world for the production of heavy ordnance. The arsenal is being enlarged to provide in peace times the nucleus for adapting ordinary industries to the production of ordnance in war periods in addition to its own production. This is an advanced step in government policy. Open hearth steel and producer gas plants are being erected and the city and district seem destined to obtain their former high standing as an iron and steel centre. The most significant development is the purchase of the northern end of Green Island by Henry Ford and Son of Detroit, as a site for a steel factory and farm tractor plant to be operated largely by power from the government dam across the Hudson at Troy. In addition to its great collar and shirt factories, Troy has become important for the manufacture of women's shirtwaists. There is a State dam across the Hudson at Troy and factories are operated by the power here obtained. There is considerable water power on the Wynantskill and Poestenkill creeks; each stream has a fall of about 200 feet in the hills east of the city.

The city contains more than 258 concerns engaged in manufacturing and employing about 26,636 wage-earners and producing annually over $60,000,000 worth of goods.

The city is situated on a narrow alluvial plain, extending north and south along the river front for six and one-half miles. From the plain, and paralleling the river, a range of hills arises, in some places to a height of 500 feet. While most of the city is confined to the level ground, the finest residential part is on

the hills, of which the most prominent is Mount Ida. On a spur of this hill, jutting out boldly into the centre of the city, stands Prospect Park. The waterworks reservoirs are located on the hills east and northeast of the city. A new gravity system has been installed with a daily capacity of 18,000,000 gallons and the old gravity systems supplement this with 9,000,000 gallons.

There are a number of cemeteries in Troy, but Oakwood, containing 400 acres, crowns one of the hills east of the city, overlooking the valley of the Hudson opposite the delta of the Mohawk. The cemetery plateau is 300 feet above the plain, to which it inclines with precipitous sides. The Hudson is in sight for miles, while the Mohawk breaks through the hills to the west, tumbles over a rocky precipice 60 feet in height, then passes peacefully through its four mouths into the Hudson. Oakwood cemetery is a resting place for three distinguished national heroes.—Gen. John E. Wool, the commander-in-chief of the American forces in the Mexican War, Gen. George H. Thomas, "the rock of Chickamauga," and Gen. J. B. Carr of Civil War fame. General Wool's monument is a monolith 60 feet high, and weighing more than 100 tons. The Earl Crematory, a prominent object in Oakwood, is a memorial building erected at great cost, and contains, aside from a perfect incinerating apparatus, some fine mosaics, rare marbles and rich stained glass. The streets of Troy are regularly laid out until the river front is reached, when the streets are intersected by River street, which follows the curvatures of the Hudson River. These irregular intersections form triangles misnamed squares. In one of these stands the Soldiers' and Sailors' monument, 93 feet high, costing over $50,000. On the lower sides of the stone work are bronze bas-reliefs representing battle scenes; one of them being a representation of the engagement between the *Monitor* and the *Merrimac*. This is a particularly appropriate scene because most of the armor plate of the *Monitor* was rolled in Troy. There are 100 miles of streets in Troy, of which 65.22 miles are paved.

Buildings.— Troy has many public buildings of note and many of its citizens have built beautiful and substantial memorials for charitable and educational work. Troy has developed as an educational centre during recent years through the endowments of Mrs. Russell Sage, the widow of the noted financier, Russell Sage, who was a former resident of Troy. The gifts of Mrs. Sage have given an impetus to old institutions and enabled them to add extensions. The Emma Willard School has been removed from the central section of Troy and located in a new group of fine buildings, in the eastern section of Troy on the hills, overlooking the Hudson Valley and the Berkshires. The former home of the Emma Willard School has been converted into a women's college of applied arts and has an enrolment exceeding 300. Another educational enterprise which has done much to make Troy famous is the Rensselaer Polytechnic Institute (q.v.), an excellent school of civil engineering. Its graduates have designed some of the greatest engineering works of modern times. Extensive additions have been made to the Rensselaer Polytechnic Institute through the aid of Mrs. Sage. It enrolls about 1,000 students. The post office, a fine granite structure; the savings bank building, which cost about $600,000, and which contains a fine Music Hall with seating capacity of 1,300; the public library, white marble in the Italian Renaissance style, cost about $300,000; the courthouse, city hall, Rowe Memorial, Young Men's Christian Association, Young Women's Christian Association; R. P. I Alumni, Ilium and other commercial buildings, the Union station, a high school and the Rensselaer Hotel are among the city's notable structures. The leading charitable and religious institutions are the Troy Orphan Asylum, a group of buildings of the Elizabethan style of architecture; three Roman Catholic orphanages, a reformatory, a home for the aged, three hospitals, several very fine churches, and the Salvation Army Temple. The public and parish school buildings recently erected are all models of completeness and beautiful architecture.

Finances.— The assessed valuation of taxable property is $61,194,631, of which $55,700,114 is for real estate, and the net bonded debt $4,379,620. The maintenance and operation of the city in 1919 was $1,256,360. There are several national banks, one State bank and two trust companies. There is one savings bank and three building and loan associations.

Government.— Troy is governed as a second class city of the State of New York and in addition to general State laws retains features of its old charter. The city is well governed, the principal problem being the comparatively great length, narrow width and steep grade of some streets leading to the residential districts on the heights to the East. The State of New York and city of Troy are co-operating in the erection of an extensive system of docks to serve as terminals for traffic created by the New York State Barge Canal system.

History.— The site of Troy was the seat of several farms, in 1786, when Albany had been called a city for a hundred years. The Mohegan Indians formerly had a fortified village on the site of Troy at a point just north of the Poestenkill Creek. The Mohawk tribe of Indians had a palisaded village on the west side of the Hudson River on an island formed by the third and fourth branches of the Mohawk River at its mouth. Hostilities broke out between tribes, in which the Mohawks were successful, and the Mohegans were finally driven to the Connecticut River. The Dutch families, who afterward took possession of this ground on the east side of the river, found a natural meadow land, and they called it "Pafraets Dael," "The paradise of a lazy man."

The islands forming the delta of the Mohawk River, opposite Troy, were the scene of much activity during the Revolutionary War. The American army encamped here to obstruct the march of Burgoyne. The island which was formerly the site of the Mohawk Indian village, above referred to, was fortified on its north side by earthworks, under the superintendence of Thaddeus Kosciuszco. Gen. Philip Schuyler commanded the American troops, with his headquarters at Van Schaick's house, which is still standing. The fortifications may yet be plainly seen. From these islands the American

army marched north under General Gates, who succeeded Schuyler, and soon afterward fought the British at Schuylerville in what is known as the battle of Saratoga.

Three miles above the site of Troy stood a village called New City, afterward Lansingburg. In 1787 New City had nearly 500 inhabitants, Albany had about 3,000, and Troy consisted of a few farmhouses. The deeper channel in the river at Troy made navigation so much easier than at New City that the enterprising settlers who began to arrive from New England, seeing its advantages, located here. The settlement grew rapidly, being known at this time as "Van der Heyden's." In 1789 the settlers changed the name to Troy. The falls on the Poestenkill Creek were taken advantage of, and three mills were here erected, a saw mill, a grist mill and a paper mill; the last, the first of its kind in northern New York, was built in 1792. In 1808 a rolling mill was established on the Wynantskill Creek. Troy soon outstripped Lansingburg, and in 1793 the State legislature decided on Troy as the county-seat of Rensselaer County.

During the War of 1812 the merchants of Troy supplied large quantities of provisions to the American army. Samuel Willson, who slaughtered cattle and packed beef in Troy, supplied his beef to the army "packed in full bound barrels of white oak." It soon became known as "Uncle Sam's," as Samuel Willson was familiarly called, and from this grew the well-known appellation, "Uncle Sam," as applied to the United States.

The charter incorporating Troy as a city was passed by the legislature in 1816.

The State dam was constructed across the Hudson River at Troy in 1823. This marks the tidal point of the Hudson River. At this time commerce with New York was mainly by sloops, of which 39 were recorded as owned by Troy merchants. In addition to its rapidly growing commerce, Troy now began to acquire fame as an educational city; the Emma Willard Seminary, established in 1814 and removed to Troy two years later, was developing a national fame; and in 1825 the Rensselaer Polytechnic Institute was opened. The population of Troy was now 7,859. The population and industries increased rapidly, and it became an important manufacturing centre. Its collar and cuff and iron industries gave its growth a great impetus. Its remoteness from the mines has caused it to lose its supremacy in the iron industries, but the collar and cuff industry has steadily increased. Industrially, the city is noted for having a group of precision industries, that is, works where machining is done to a standard of one one-thousandths of an inch instead of the usual machine shop standard of one one-hundredths-inch. This was the determining factor in the government enlarging the Watervliet arsenal during the war and after the war. Precision trained mechanics of this sort are found in few other centres in America. Troy has had several destructive fires. The most notable was the one of 10 May 1862, when the total value of property destroyed was $2,677,892; about 800 buildings were burned.

The village of Lansingburg and the city of Troy gradually grew toward each other until the dividing line was not apparent to the eye, yet each maintained its separate government. In 1900 an act was passed by the legislature annexing Lansingburg and other outlying territory to the city of Troy. This act did not take effect until 1 Jan. 1901, too late to receive notice in the United States census of 1900. However, an enumeration was taken by the census officials, as shown in the census reports, giving the population of Greater Troy as 75,057. The population at present is estimated at 80,000. Consult Weise, 'Troy's One Hundred Years.'

ARTHUR J. BURCH,
Secretary of Troy Chamber of Commerce.

TROY, Ohio, village, county-seat of Miami County, on the Miami River, the Miami and Erie Canal, and on the Cleveland, Cincinnati, Chicago and Saint Louis and the Cincinnati, Hamilton and Dayton railroads, about 20 miles north of Dayton. It was located in 1807 in an agricultural and stock-raising region, and has considerable manufacturing interests, being incorporated in 1890. The principal manufactories are planing mills, foundries, bent wood and wagon factories, and a flour and grist mill. There is considerable trade in farm and dairy products, and in the local manufactures. The educational institutions are a high school, Saint Patrick's Academy, public and parish schools and a public library. The two banks have a combined capital of $300,000. Pop. 6,122.

TROY WEIGHT. See WEIGHTS AND MEASURES.

TROYES, trwä, France, capital of the department of Aube, and formerly of the province of Champagne, 103 miles east-southeast of Paris by rail, on the left bank of the Seine. Many of the streets are narrow and irregular, and lined with mediæval timber houses. The principal edifices are the cathedral, a splendid specimen of florid Gothic; the churches of Saint Urbain, of Saint John and of Saint Madeleine, in the flamboyant style; the *hôtel-de-ville,* the prefecture, the hospital, museum, *palais de justice* and public library, containing 140,000 printed volumes and nearly 15,000 manuscripts. The manufactures consist of cottons, woolens, hosiery, soap, artificial flowers, paper, gloves, etc. There are numerous worsted and cotton mills. The division of the Seine here into several arms facilitates local water transportation. It carries on an important trade in grain, wine, brandy, colonial produce, famous sausages, hemp, wax, wool, wood, iron, lead, zinc, etc. The town was in existence previous to the conquest of Gaul by the Romans, by whom it was called Augustobona. The Treaty of Troyes between Charles VI and Henry V of England was concluded in 1420. Nine years later the English were expelled by Joan of Arc. The revocation of the Edict of Nantes in 1685 intertered with trade, so the population was reduced from about 40,000 to 24,000. It has since recovered, and in 1911 was 55,486.

TROYLUS AND CRYSEYDE. One of Geoffrey Chaucer's poems, written about 1380 and supposed to be a translation from Boccaccio. The episode first appears in a 12th century romance. See TROILUS AND CRISEYDE.

TROYON, trwä-yôn, **Constant,** French painter: b. Sevres, 25 Aug. 1810; d. Paris, 21 Feb. 1865. He was one of the first and greatest of the French "Naturalists," and was

trained as a painter on porcelain. His pictures rank high among those of his contemporaries, and his cattle and landscapes rival the best productions of the Dutch school. He excelled in natural presentation of the familiar views of cattle in the fields and on the farms and was very prolific. The large French galleries all have numerous samples from his brush. There are several good examples of his work in the New York Metropolitan Museum, and among them 'Cow,' 'On the Road' and 'Landscape and Cattle.' Consult Dumesnil, 'Constant Troyon' (1888), and Hustin, 'Les Naturalistes Français' (1893). The Brooklyn Institute, the Art Institute in Chicago, the Corcoran Gallery in Washington and others in Philadelphia and San Francisco have many of his canvasses. Consult Hustin, A., 'Constant Troyon' (Paris 1893); Gansel, W., 'Cosot und Troyon' (1906).

TROZO, trō'thō, or **SAN JOSÉ,** sän hō-sā', Philippines, a suburb of the city of Manila, occupying the centre of the northeast quarter of the city, southeast of Tondo. The people are largely engaged in the mechanical industries; there are also a few Chinese and native residents of the upper class.

TRUANT SCHOOL, the popular name for a school or reformatory for truant or vagabond children; organized under State auspices and managed by the State educational officials. In 1850 Massachusetts passed a law permitting the punishment of truancy by confinement. New Hampshire, New York, Rhode Island and Connecticut made similar legislation before 1865, and New York and other cities made like provisions; but where the law was not a dead letter, habitual truants were classed as "juvenile disorderly persons" and were sent to almshouses or reformatories. In 1880 Massachusetts began to establish county schools for truants, and several were established in large cities elsewhere. Many States and cities provide for the arrest of truants and their being replaced in the public schools, a method followed in Continental Europe, where there are no institutions exactly parallel to the American truant school. In Great Britain there are two provisions for school offenders, the day industrial and the truant schools, based on the Industrial Schools Act of 1866, for "any child found habitually wandering or not under proper control, or in the company of rogues, vagabonds disorderly persons, or reputed criminals"; or any child whose parents neglect to provide for its instruction. See CHILDREN'S COURTS; PUBLIC SCHOOLS.

TRÜBNER, Nicholas, London publisher: b. Heidelberg, Germany, 1817; d. London, England, 1884. He learned his trade abroad and on coming to London was employed by Longmans for a time but in 1851 entered in business for himself and speedily became the head of Trübner and Company. He published a 'Bibliographical Guide to American Literature' (1855), which was enlarged four years later; also 'Trübner's Oriental Series' and the 'British and Foreign Philosophical Library.'

TRUCE, a temporary suspension of hostilities between two armies or states for negotiation or other purposes. It has almost the meaning of armistice, but suggests a more local understanding. A truce may, however, apply either to all the operations of a war or to those at one place only, as a truce after a battle for carrying off the wounded. A truce to become generally binding requires the sanction of the commander-in-chief, it may be ended before the period previously agreed upon if due notice be given to the opposite party.

TRUCE OF GOD, the title given in the Middle Ages to a limitation of the right of private warfare introduced by the Church in order to mitigate an evil which it was unable to eradicate. This truce of God provided that private feuds should cease, at least on the holy days, from Thursday evening to Sunday evening in each week; also during the whole season of Advent and Lent and on the octaves of the great festivals. The salutary regulation was first introduced in 1033 in Aquitaine, then in France and Burgundy. Under William the Conqueror it was introduced into England, and in 1071 into the Netherlands. At many councils it was a chief subject of discussion and was enjoined by special decrees. Whoever engaged in private warfare on the prohibited days was excommunicated. The truce of God was also extended to certain places, as churches, convents, hospitals, churchyards, etc., and certain persons, as clergymen, peasants, merchants, pilgrims and, in general, all defenseless persons. At the Council of Clermont (1095) it was made to include all Crusaders. This institution died out when the rulers of the various countries became strong enough to curb effectually their turbulent and powerful subjects.

TRUCK, Motor. See MOTOR TRUCK.

TRUCK ENGINE. See INTERNAL COMBUSTION ENGINE.

TRUCK FARMING. See HORTICULTURE.

TRUCK SYSTEM, the practice of paying the wages of workmen in goods instead of money. This practice has prevailed in various places and trades, particularly in the mining and manufacturing districts of Great Britain, and the workmen have often had to pay exorbitant prices for their goods. Several acts of Parliament have been passed with the object of abolishing the system. In the United States the system was common in the Pennsylvania coal fields where miners are paid in store checks; at the end of the week or month their wages have been consumed by rent, supplies, groceries and other necessaries of life. In most of the States it is now prohibited by law.

TRUCKEE, trŭk-ē', a river, the outlet of Lake Tahoe in California. It flows north, then enters Nevada and flows east, then north, entering Pyramid Lake, which has no apparent outlet. The river is about 100 miles long. Reno, Nev., is the most important town on the river.

TRUDEAU, Edward Livingston, American physician: b. New York, 5 Oct. 1848; d. 15 Nov. 1915. In 1871 he was graduated at the College of Physicians and Surgeons, New York, and established his practice in that city. Attacked by tuberculosis he removed to the region of Saranac Lake in 1873, and there remained until his death. In 1884 he founded a sanitarium for the treatment and cure of incipient tuberculosis among the poorer classes. For many years Dr. Trudeau followed the open-air method of treatment, and in 1894

founed the Saranac Laboratory for the study of tuberculosis, the first of its kind in America. Robert Louis Stevenson was among his most noted patients. He was recognized in America and abroad as the foremost authority on tuberculosis and on methods for combating it. In 1905 he was president of the Association of American Physicians, and five years later of the Congress of American Physicians and Surgeons. He became first president of the National Association for the Study and Prevention of Tuberculosis. Consult his 'An Autobiography' (Garden City, N. Y., 1916) and Chalmers, Stephen, 'The Beloved Physician' (Boston 1916).

TRUE, Alfred Charles, American educator and agriculturist: b. Middletown, Conn., 5 June 1853. He was graduated at Wesleyan University, Connecticut, from which he also received a degrees of D.Sc., and after a graduate course at Harvard, 1882–84, was an instructor at Wesleyan, 1884–88. He then entered the United States Department of Agriculture; was successively editor, vice-director and director (1888–1915) of the office of experiment stations, and became director of the State Relation Service in 1915. For many years he was editor-in-chief of the *Experiment Station Record* and the *Experiment Station Work;* and had charge of investigations in irrigation, drainage and human nutrition. He still has supervision of the Federal work and expenditures for agricultural experiment stations in all the States and in Alaska, Porto Rico, Hawaii and Guam, and for co-operative extension work in agriculture and home economics throughout the United States under the Smith-Lever Act of 8 May 1914, together with investigations in home economics and agricultural education. In 1914 he was president of the Association of American Agricultural Colleges and Experiment Stations, and since 1902 has been dean of the Graduate School of Agriculture maintained by the association. He is the author of monographs on agricultural experiment stations in the United States and on agricultural education.

TRUE, Charles Kittredge, American educator: b. Portland, Me., 14 Aug. 1809; d. Brooklyn, N. Y., 20 June 1878. He was graduated at Harvard in 1832, was subsequently pastor of several Methodist churches and principal of the Amenia Seminary. In 1849 he received the degree of D.D., from Harvard, and was professor of moral philosophy at Wesleyan University (1849–60). He was a ready writer and produced many books, notably 'Life and Times of John Knox' (1874); 'The Thirty Years' War' (1879), and the 'Life of Captain John Smith' (1882).

TRUE, Frederick William, American biologist: b. Middletown, Conn., 8 July 1858. He was graduated at the University of the City of New York in 1878; entered the government service in 1878; and was expert special agent on fisheries for the 10th census, 1879. He was curator of the department of mammalia at the United States Museum, 1881–92, an executive curator, 1892–97. In the year last named he was appointed head curator of the department of biology at the United States National Museum. He has written 'Review of the Family of Delphinidæ'; 'Whalebone Whales of the Western North Atlantic' (1904); 'Observations on Living White Whales' (1911), etc.

TRUE, Rodney Howard, American botanist and physiologist: b. Greenfield, Wis., 14 Oct. 1866. His education was secured at the University of Wisconsin and at Leipzig, where he took his Ph.D. degree (1895). He taught in the schools of Wisconsin, was made a lecturer in botany in Harvard in 1900–01, since which time he has been in charge of physiological investigations for the United States Department of Agriculture. His writings though voluminous are chiefly contributions to scientific journals.

TRUEBA Y COSÍO, Telesforo De, Spanish author: b. Santander, Spain, 1798; d. Paris, 1835. He was educated in a Catholic college in England, and served as an attaché to the Spanish legation there until 1822. Returing to Spain he founded an academy of the younger generation of poets and wrote two comedies which rank with the best productions of the time. Subsequently he fled for political reasons to London, where he gained repute as a fluent English writer. His greatest success was won by his description of manners, 'Paris and London' (1831). He returned to Spain in 1834, and was elected to the Cortes.

TRUEBLOOD, Benjamin Franklin, American publicist: b. Salem, Ind., 25 Nov. 1847; d. Newton Highlands, Mass., 26 Oct. 1916. He was graduated from Earlham College, Richmond, Ind., in 1869; entered the ministry of the Society of Friends the same year, and was president of Wilmington (Ohio) College, 1874–79. He was president of Penn College, Oskaloosa, Iowa, 1879–90, and received the following honorary degrees: LL.D., Iowa Wesleyan University, 1887; LL.D., State University of Iowa, 1890; LL.D., Baylor University, Waco, Tex., 1907. Dr. Trueblood was secretary of the American Peace Society in Boston, 19 years, in Washington, four years; was editor of the *Advocate of Peace,* 1892–1915, and published 'The Federation of the World' (1899). He made translation of Kant's 'Zum ewigen Frieden' (1897); also published many pamphlets, numerous articles in magazines, gave many lectures on international subjects, participated in International Peace Congresses and many other conferences. On account of broken health he resigned the secretaryship of American Peace Society, May 1915, and was elected honorary secretary of the American Peace Society.

TRUFFLES, subterranean saprophytic fungi (q.v.), chiefly European *Tuberaceæ,* the mycelia of which grow in leaf-mold. Their fructifications are edible, solid tuber-like bodies, ranging from the size of a filbert to that of a potato, and ultimately set free by the decay of the mycelium. There are several species of truffles, which are not only nutritious but very much esteemed for their aromatic flavor and piquant taste, and are used in fine cooking, pâtés, etc. Although white truffles are somewhat in demand, it is the black or queen truffles (*Tuber cibarium, T. æstivum,* or *T. melanospermum*) of England and France, which are in most demand, those of Perigord being considered as the finest. These are of varying

size, and have a gray or seal-brown or nearly black skin, which is pebbled, or warty, with small angular protuberances. The firm interior, with such a texture as has an immature puff-ball, is dark-brown, somewhat mottled by reason of its chambered structure, and reticulated with the white films of hyphæ. Truffles are practically never cultivated, in spite of various attempts, but are occasionally cared for *in situ*. They thrive best in limestone soils, and in such light, moist, but well-drained woodlands, as are frequented by the various species of trees near which the truffles prefer to exist — possibly on their decaying roots. The tubers are entirely subterranean, occurring either deep in the ground or close to the surface, ripen in winter and are dug out, either laboriously by unaided man with a sharp spud, or by the aid of dogs and pigs. The latter are commonly used in Perigord, their rooting instincts and fine nose for scent being turned to account. A trained sow will sniff the peculiar pervasive odor exhaled by a ripe tuber, and will make directly for it, either laying it bare or uprooting the solitary tuber, to be rewarded with an acorn or chestnut. Good intelligent sows in a prolific forest will unearth 10 or 12 pounds of truffles in a day, which will bring in a good price. Dogs are also used in the same manner, especially by poachers. The red truffle (*Melanogaster variegatus*) is, like the false truffle (*Scleroderma vulgare*), allied to the puff-balls; and *Terfezia leonis* is the white, potato-like truffle of Italy. The African species of *Terfezia* and *Tirmannia*, somewhat inferior in quality, in some parts of Algeria and Tunis form an important food-supply for the people.

TRUJILLO, troo-hēl'yō, or **TRUXILLO,** Peru, the capital of the department of Libertad, situated close to the Pacific Coast, 320 miles northwest of Lima. It is partially surrounded by ancient adobe walls, believed to be 250 years old. It has a cathedral, a national college and a university. There are interesting ruins of a former great city four miles to the north. The port is Salavery, connected with the city by a short railroad. Many bananas are shipped north. Pop. about 8,000.

TRUMBITCH, Ante, Foreign Minister of the Serb-Croat-Slovene kingdom (1918), was born Spalato, Dalmatia, and was for many years mayor of that city. A prominent lawyer, he became president of the Dalmatian Provincial Diet and a Dalmatian deputy to the Austrian Reichsrat. He escaped from Austria on the outbreak of the war and assisted to form the Southern-Slav Committee, of which he was elected president. In July 1917 he concluded the Declaration of Corfu with Serbia — the preliminary charter of Southern-Slav unity under the Karageorgevitch dynasty. In March 1918 he also concluded the Italo-Southern-Slav agreement with Italy and was appointed Foreign Minister of the new kingdom on 22 Dec. 1918.

TRUMBULL, trŭm'bŭl, **Annie Eliot,** American novelist, daughter of J. H. Trumbull (q.v.): b. Hartford, Conn., 2 March 1857. She was graduated from the Harvard High School in 1876 and has published 'A Cape Cod Week' (1898); 'Rod's Salvation' (1898); 'Mistress Content Cradock' (1899); 'Life's Common Way' (1903) and other works.

TRUMBULL, Gurdon, brother of H. C. Trumbull (q.v.), American artist: b. Stonington, Conn., 5 May 1841; d. Hartford, Conn., 28 Dec. 1903. He learned his art in Hartford and New York. It was in studies of fish that he achieved his reputation and his most noted works were 'Over the Fall'; 'A Plunge for Life' and 'A Critical Moment.' He was the illustrator of the work of his sister, Mrs. Annie T. Slosson, 'The China Hunters' Club,' and was author of the work entitled 'Names and Portraits of Birds.'

TRUMBULL, Henry Clay, American author and editor: b. Stonington, Conn., 8 June 1830; d. Philadelphia, Pa., 8 Dec. 1903. He was educated at Williston Seminary, East Hampton, Mass., and at first engaged in railroad business at Hartford, but in 1858 became State missionary of the American Sunday School Union for Connecticut. He was ordained to the Congregationalist ministry in 1862, entered the Union army as chaplain, and served through the war with the exception of a portion of 1863, when he was held a prisoner by the Confederates. He was appointed missionary secretary for New England of the American Sunday School Union in 1865, normal secretary in 1871 and in 1875 he removed to Philadelphia. He purchased the chief interest in the Philadelphia *Sunday-School Times* in that year and was its editor until his death. He discovered the site of Kadesh-barnea on the southern border of Palestine while on a tour of the East in 1881. His works include 'The Sabbath School Concert' (1861); 'The Knightly Soldier' (1865); 'Kadesh-barnea' (1884); 'Studies in Oriental Social Life' (1894); 'War Memories of an Army Chaplain' (1898); 'Old Time Student Volunteers' (1902), etc.

TRUMBULL, James Hammond, American philologist, brother of H. C. Trumbull (q.v.): b. Stonington, Conn., 20 Dec. 1821; d. Hartford, Conn., 5 Aug. 1897. He was educated at Yale, assisted Rev. James H. Linsley in compiling catalogues of the mammalia, reptiles, fishes and shells of Connecticut in 1842–43, was assistant secretary of the State of Connecticut in 1847–52 and again in 1858–61, and secretary during the Civil War, 1861–65. He was corresponding secretary of the Connecticut Historical Society in 1849–63, and its president in 1863–89. In 1863–91 he was librarian of the Watkinson Library of Reference at Hartford, was an original member of the American Philological Society from its organization in 1869 and was its president in 1874–75. He was elected to the National Academy of Sciences in 1872 and was appointed lecturer on the Indian languages of North America at Yale in 1873. He prepared the catalogue of Americana belonging to George Brinley which added much to his reputation as a bibliographer, and devoted the closing years of his life to the compilation of a dictionary and vocabulary from John Eliot's Indian Bible, which he was reputed to be the only living American able to read. His manuscript was published under the title 'Natick Dictionary' (1903). His other works include 'Colonial Records of Connecticut' (3 vols., 1850–59); 'The Best Method of Studying the Indian Languages' (1871); 'Historical Notes on the Constitution of Connecticut' (1872); 'Indian Names of Places in

and on the Borders of Connecticut with Interpretations' (1881); 'Memorial History of Hartford County' (2 vols., 1886), etc.

TRUMBULL, John, American jurist and poet: b. Westbury (now Waterbury), Conn., 24 April 1750; d. Detroit, Mich., 10 May 1831. Graduated at Yale in 1767, he began in 1770 to contribute to the *Connecticut Journal* and *New Haven Post-Boy* a series of essays called 'The Correspondent,' patterned after 'The Spectator,' in which he satirized the controversial writers of the time and the American slave-traffic; and published in that year 'An Essay on the Use and Advantages of the Fine Arts.' In 1771 he became a tutor in Yale and began the study of law, which he continued in John Adams' Boston office in 1773, in which year he was admitted to the bar. He practised at New Haven in 1774–76, at Westbury in 1776–81 and from that time at Hartford. In 1789–95 he was State's attorney for Hartford County, in 1792 and 1800 was elected to the legislature, in 1801–07 was judge of the Connecticut Superior Court, and in 1808–19 of the Court of Errors. From 1825 he resided at Detroit. His 'Progress of Dulness' (Part I, 1772; Part II, 1773) was his first elaborate work in verse. It was a clever satire on the defective culture of contemporary American society, and its epigrammatic ridicule made a great stir. But he is known for 'McFingal' (1782), a burlesque epic, in the metre and much in the style of 'Hudibras,' which it follows, however, without sacrifice of originality. It admirably developed the humorous characteristics of that disturbed time, and from the first had an unprecedented popularity. Its hero is Squire McFingal, a Scottish-American Tory politician of Massachusetts, with a gift for tedious and inflated speechifying; his Whig opponent, Honorius, seems to be, according to Tyler, a portrait of John Adams. It was the most representative of the distinctly literary productions of the Revolution, to whose movement it greatly contributed. No contemporaneous record presents so well the thought of the period. In pointedness, in ingenuity of rhyme, in the skilful arrangement of its ludicrous narrative, it is admirable. Many extracts such as:

> "No man e'er felt the halter draw,
> With good opinion of the law,"

passed into the general anthology of quotations. It was reprinted by Lossing, with introduction and notes, in 1857, and another edition of it appeared in 1881. In all, about 40 editions have been circulated in the United States and England. For its full understanding the work now requires some study of the Revolutionary epoch. Trumbull's 'Poetical Works' were collected in 1820. Consult the excellent account in Tyler, 'Literary History of the American Revolution' (1897).

TRUMBULL, John, American artist: b. Lebanon, Conn., 6 June 1756; d. New York, 10 Nov. 1843. He was graduated at Harvard in 1773; studied painting in Boston; served in the Revolutionary War; and in 1780 went to England to study under West, but was imprisoned on a charge of treason and forced to leave the country. Subsequently he returned to England and became the pupil of West. In 1786 he produced his first historical picture, the 'Battle of Bunker Hill'; which was soon followed by the 'Death of Montgomery Before Quebec' and 'Sortie of the Garrison from Gibraltar.' In 1817 he was employed by Congress to paint four pictures for the rotunda of the Capitol at Washington, namely 'The Declaration of Independence,' the 'Surrender of Burgoyne,' the 'Surrender of Cornwallis,' and the 'Resignation of Washington at Annapolis.' He was for many years engaged in finishing his sketches, many of which, together with portraits and copies of old masters, 54 pictures in all, he surrendered to Yale College in consideration of an annuity of $1,000. Consult his 'Autobiography' (1841).

TRUMBULL, Jonathan, American patriot: b. Lebanon, Conn., 12 Oct. 1710; d. there, 17 Aug. 1785. Graduated from Harvard in 1727, he studied theology and was licensed, but in 1731 left the ministry for the law, was a member of the assembly in 1733, its speaker in 1739, and deputy-governor in 1767–68. From 1769 until his resignation in 1783 he was governor. During the Revolution he worked with vigor for independence. He is said to have been the original "Brother Jonathan" (q.v.), that being Washington's familiar name for him. He was the only colonial governor to take the popular side in the struggle; and when notified by Washington (August 1776) of the inadequacy of the army, called for nine more regiments of 350 each, in addition to the five Connecticut regiments already supplied. These troops arrived at New York just in time to meet the British advance. In 1766–69 Trumbull was also chief justice of the Superior Court of Connecticut, and as such he has been highly praised by Bancroft. Consult the 'Life' by Stuart (1857).

TRUMBULL, Jonathan, American politician, son of the preceding: b. Lebanon, Conn., 26 March 1740; d. there, 7 Aug. 1809. He was graduated from Harvard in 1759, and prior to the Revolution was a member of the Connecticut legislature and speaker of the house. He was paymaster-general in the Connecticut army, 1775–80, and military secretary to Washington, 1780–83. He sat in Congress, 1789–95, being speaker of the House of Representatives, 1791–95, was United States senator, 1795–96, lieutenant-governor of Connecticut, 1796–98, and governor from 1798 till his death.

TRUMBULL, Joseph, American statesman: b. Lebanon, Conn., 7 Dec. 1782; d. Hartford, Conn., 4 Aug. 1861. He was graduated at Yale in 1801, was admitted to the bar at Windham in 1803 and settled in Hartford where he practised until 1828. He represented Hartford in the legislature in 1832–48 and in 1851, was representative in Congress in 1839–43 and in 1849–50 was governor of Connecticut.

TRUMBULL, Lyman, American politician: b. Colchester, Conn., 12 Oct. 1813; d. Chicago, Ill., 25 June 1896. He studied law in Georgia, was admitted to the bar and settled in Belleville, Ill., in 1837. He was secretary of state of Illinois in 1841–42; and justice of the Supreme Court of the State in 1848–53. He was United States senator, 1855–73, and although formerly a Democrat, became prominent as a Republican. He secured the passage of the 14th Amendment; and was one of the Republicans who voted

against the impeachment of Andrew Johnson. After 1872 he supported the Democratic party.

TRUMPET, a musical wind-instrument with a flaring mouth, generally made of brass, and sometimes of silver. Primitive trumpets were straight tubes. The curves were introduced to shorten the length. Slides, valves and keys are now added. (See HORN). The orchestral or slide trumpet consists of a tube about five and one-half feet long, twice curved, and ending in an open cone. The slide is on the second curve. The scale of the slide trumpet begins with A sharp in the first space of the brass stave, and extends to C above the treble stave, but C below the bass stave can be produced. The natural notes are C (below bass), C (octave), G, middle C, E, G, B flat, C, D, E, F, G, A, B flat, B, C. A univalve trumpet was introduced by Bassett in 1876. The addition of the valve greatly improves the slide trumpet in accuracy and completeness without injuring its characteristic tone. The trumpet, with its thrilling notes and bugle calls, is well fitted for military music.

TRUMPET-FISH, or **TRUMPETER,** one of the most important food-fishes (*Latris hecateia*) of the southern hemisphere. It ranges from 30 to 60 pounds in weight and is considered the best flavored of any of the fishes of New Zealand, Tasmania and South Australia. Large numbers are smoked and sent into the interior.

The name is also applied to several species of fishes belonging to the small families *Aulostomidæ, Fistulariidæ* and *Macrorhamphosidæ,* all belonging to the order *Hemibranchii,* and all having the facial bones much elongated to form a tube bearing the small nearly or quite toothless mouth at the end. They are fishes of peculiar aspect, the body as well as the head being elongated and sometimes protected by bony plates, and in the *Fistulariidæ* the caudal fin bears a pair of long, slender filaments. These fishes are variously known also as tobacco-pipe fishes, cornet-fishes, snipe-fishes and bellows-fishes, all these names having reference to the tubular snout. They are tropical, and species of each family occur in the Gulf of Mexico and the southern waters of the United States.

TRUMPET-FLOWERS, plants belonging to *Tecoma* and *Bignonia* and allied genera of the family *Bignoniaceæ,* having trusses of gaily-colored flowers with funnel-form corollas. *Campsis grandiflora* is the showy trumpet-flower or trumpet-creeper from China, with drooping, salmon-yellow and scarlet flowers three inches broad, but is not so hardy as the American *C. radicans,* which is a very common shrub of the South, and is called Virginia trumpet-flower by foreigners. It climbs high by rootlets, sending out long, pendulous sprays with opposite pinnate leaves which end in a corymb of tubular flowers, orange colored as to the tubes, and expanding into a five-lobed scarlet limb. Both of these species are planted extensively, as ornamental vines, to cover walls, verandas, etc. The yellow elder, or upright trumpet-flower (*Tecoma stans*), is an evergreen shrub of erect growth introduced from Central America, and growing readily in southern Florida. The leaves are pinnate, and immense panicles of golden-yellow flowers bend down the branches with the weight of their bloom. The Cape honey-suckle (*Tecomaria capensis*) is an evergreen climber which can be trained into shrub form, and is useful for Florida; it can also be grown as a climber, or as a pot-plant, in northern greenhouses. *Bignonia venusta* of Brazil is another greenhouse climber in the North, but can be grown out of doors in warm climates. Its hanging, string-like shoots are clothed with axillary and terminal clusters of large tubular orange-yellow flowers, for four or five feet of their length. The cross-vine, or quarter-vine (*B. crucigera*) of the southern United States, so called because a transverse section of the stem shows a cruciform marking, is also known as the tendriled trumpet-flower. The leaves are pinnate with only two leaflets, and terminate in a branched tendril; the flowers are large and campanulate with undulate or slightly lobed limb borne in few-flowered cymes. *Gelsemium sempervirens,* formerly classified among bignonias, is not only called yellow jasmine, but also the evergreen trumpet-flower. Various species of *Solandra, Brunfelsia, Catalpa,* and *Datura,* are known as trumpet-flowers; especially tropical tree-species of *Datura,* such as in Java form boundary hedges about the coffee plantations, and are a marked feature in the landscape. *Thevetia neriifolia,* of tropical America, is an oleander-like, poisonous plant, with yellow, fragrant flowers, and curious fruit, and is known as yellow-oleander, or trumpet-flower; it grows luxuriantly in Florida.

TRUMPET SHELL, a large marine gasteropod (*Triton variegatus*) of the South Seas. The shell, which is a foot or more in length, is white mottled in irregular spiral rows with ruddy brown and yellow, deepening into chestnut at the point; interior white; lip with smooth white ridge on a black ground. It is employed by the Australian natives and the South Sea Islanders as a trumpet. To fit the shell for this purpose a round hole is bored at the side, about one-fourth the length from the tip, and a loud hoarse sound is produced by blowing across the hole, as a performer plays a flute. While blowing, the right hand is placed in the cavity of the shell. The large conch shells of the West Indies are frequently pierced and used for the same purpose.

TRUMPETER, a genus (*Psophia*) of wading-birds, related to the cranes, found in South America, and so named from their hollow cry, which results from the peculiar conformation of the windpipe or trachea. The bill is short and stout, and except for their long legs and necks these birds resemble fowls. The most familiar species is the golden-breasted trumpeter (*P. crepitans*), which is readily tamed and becomes a favorite inmate of the house. The head and neck are velvety-black; the breast is glossy-green; the back gray; and the wings, tail and under parts black. This species, like the others, lives in the forests in flocks; and feeds upon fruit, seeds and insects. They run swiftly but seldom fly. The eggs, numbering 10 or 12, are light-green in color, and are deposited in a mere hole scratched in the ground. Only about five other species are known, all belonging to the single genus and constituting the family *Psophidæ.* A large North American swan (*Olor buccinator*) has also borne the name. See TRUMPET-FISH.

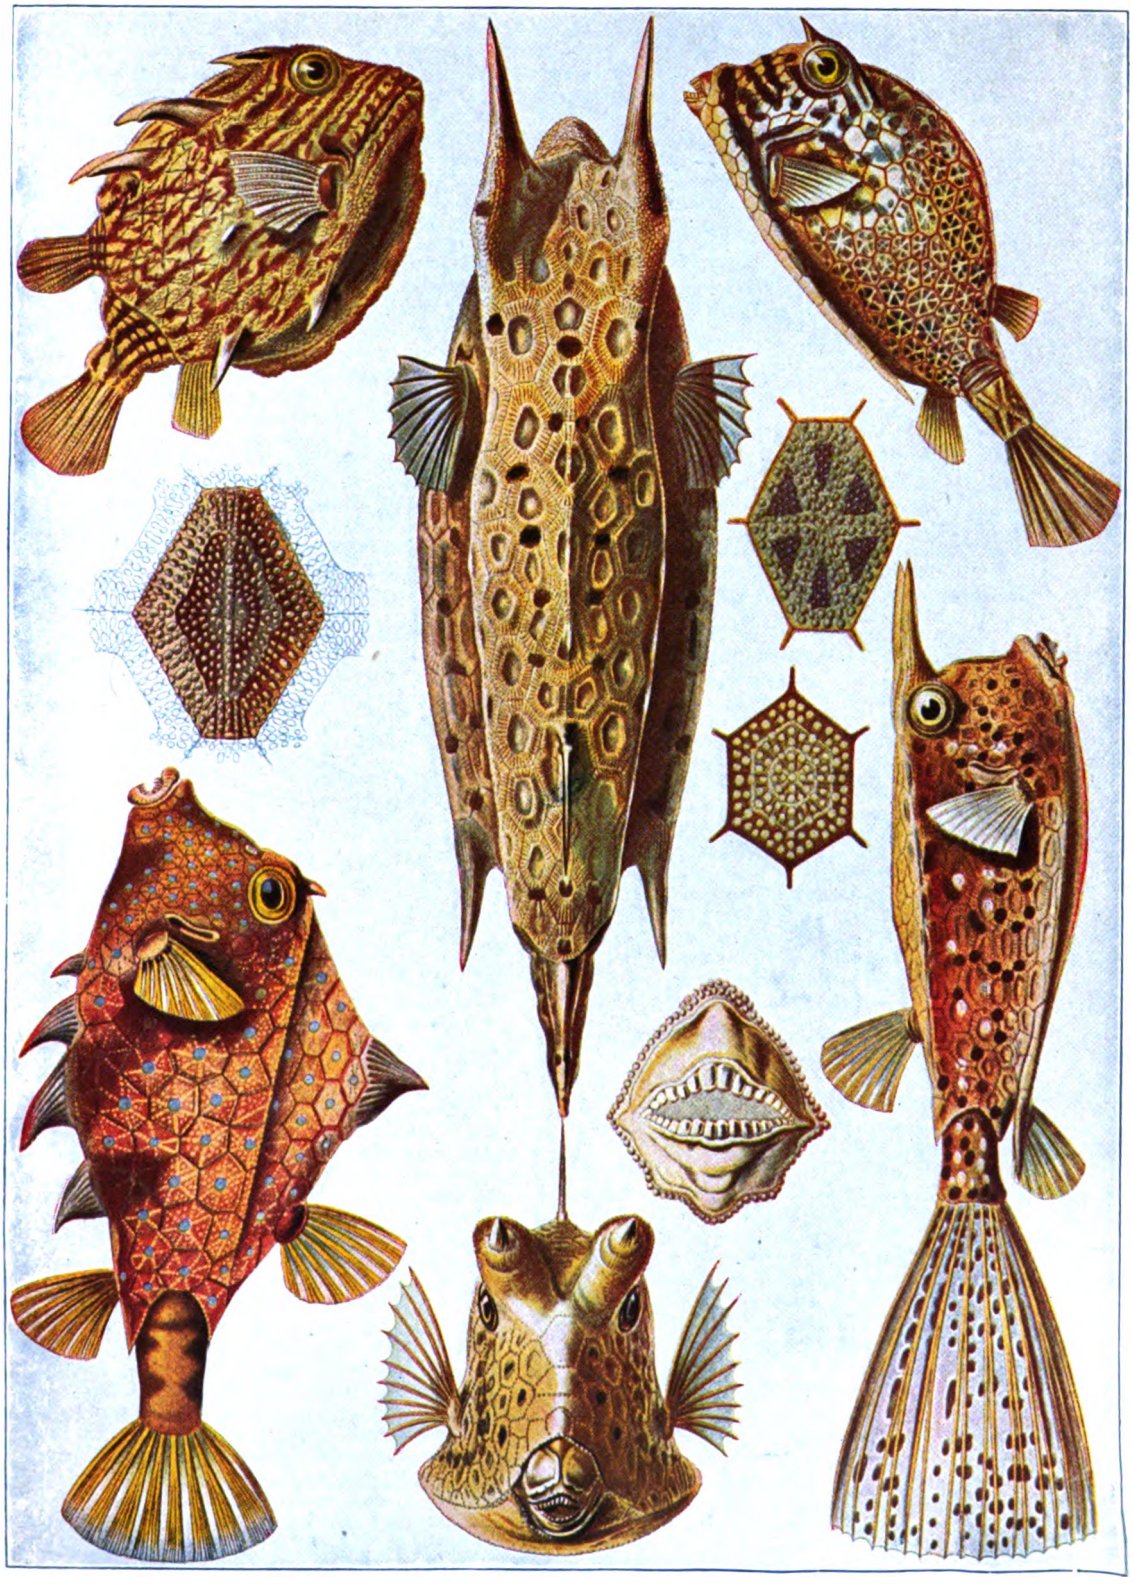
TRUMPETER, a [illegible]



TRUNK FISH

TRUMPETER OF SÄKKINGEN, The. The Trumpeter of Säkkingen (Der Trompeter von Säkkingen, 1853) by Joseph Viktor von Scheffel, the most widely read of modern German stories in verse, blends the 17th century tradition of the checkered but finally happy love of a musician of Säkkingen and a baron's daughter with experiences of Scheffel's varied life. The narrative, humorous, thoughtful and quizzically satirical, interspersed with songs, grave and gay, tells first how Werner, student musician, under the protection of the Pastor (Scheffel's friend Riesterer of Rickenbach) becomes music teacher to the squire's daughter Margareta. Their loves are rudely sundered by the paternal aristocrat. Werner, going to Rome, becomes band-master to Pope Innocent XI. At a pontifical function 1 July 1679, Margareta recognizes Werner and swoons. The Pope, learning their story, ennobles Werner, unites the lovers and procures the squire's blessing. Sardonic comments and lyrics by the Pastor's cat, Hiddegeigei, on the course of true love are possibly a bitter-sweet echo of Scheffel's own disappointment in his love affair with his cousin Emma Heim. The Silent Man reflects the author's political disillusions of 1848. There are over 300 German editions of the 'Trumpeter.' It has been best rendered in English by T. Martin (1893).

BENJAMIN W. WELLS.

TRUMPETS, Feast of, a Jewish feast on the first and second days of the seventh month (Tisri), which was to be kept as "a sabbath, a memorial of blowing of trumpets, an holy convocation." No servile work was to be done on it; but an offering of fire was to be presented to Jehovah (Lev. xxiii, 23–25). It preceded by 10 days the Great Day of Atonement (27). In Numbers (xxix, 1–6), details are added as to the "offering of fire," which was to include the burnt offering, a meat offering, and a sin offering. The first of Tisri was New Year's Day of the civil year. It is still observed as a Jewish festival.

TRUNK, a light strong oblong box, now usually made of wood, cloth, leather or fibre, with metal corners, fastenings, locks, etc., used by travelers as a receptacle for clothing and other personal belongings. In the 18th century few trunks were needed as there was little traveling. The business of manufacture was then generally conducted by those who were saddlery and harness makers. It has long been a staple business, and of recent years shows a tendency to specialize. The most popular modern trunk is the wardrobe trunk, made to stand on one end, with supports for hanging gowns, coats, trousers, etc., and also a set of drawers with dressing case conveniences. Another specialty is the auto-trunk made in a variety of shapes to fit odd spaces in automobiles. In New York in 1840 there were 11 makers, and in 1901 there were five large factories whose sales amounted to $2,000,000. In the United States in 1905 there were 373 establishments engaged in the manufacture of trunks and valises, paying out $4,139,034 in wages. In 1914 there were 561 manufacturers in the country, employing over 10,000 people, using a capital of $18,571,000 and producing goods to the total value of $26,477,000, of which $12,847,000 represented actual production, the balance being cost of materials. Trunks and valises to a value of about $1,000,000 were manufactured in addition by other industries. This showing, however, represented a falling off of about 10 per cent as compared with 1909. New York State manufactures over one-fourth of all the trunks made in the United States and Pennsylvania, Illinois and Virginia come next.

TRUNK-BACK. See LEATHER-TURTLE.

TRUNK-FISH. A variety of fish of the order *Plectognathi* and the sub-order *Ostracodermi.* See COFFER-FISH.

TRUNK-HOSE, a kind of short wide breeches gathered in above the knees, or immediately under them, and distinguished according to their peculiar cut as French, Gallic or Venetian. This garment prevailed during the time of Henry VIII, Elizabeth and James I.

TRURO, troo'rō, **Thomas Wilde,** BARON, English statesman: b. London, 7 July 1782; d. there, 11 Nov. 1855. He was educated at Saint Paul's School, studied law, and in 1817 was called to the bar. He was retained for the defense of Queen Caroline in 1820 and made himself famous by his conduct of the case. He entered Parliament in 1831, sitting for Newark-on-Trent, and continued to hold that seat until 1841, with the exception of the years 1832–35. He subsequently represented Worcester until 1850 when he took his place in the House of Lords. He was appointed Solicitor-General in 1839, and Attorney-General in 1841, though he occupied the latter office but a few months. He introduced Rowland Hill's postal reform plan to the House in 1843, and in 1846 was reappointed Attorney-General by Lord Russell, an office which he vacated a few days later to become chief justice of the Court of Common Pleas. He was sworn as lord-chancellor in 1850 and at the same time was created Baron Truro. His career as chancellor was eminently successful, a fitting conclusion to his long and honorable career.

TRUSDELL, Charles Gregory, American philanthropist: b. Montgomery, N. Y., 1 May 1826; d. Chicago, Ill., 16 Feb. 1903. He received an academic education, studied theology, and in 1857 was ordained in the Methodist ministry. He held various charges in Iowa until 1865, in which year he became presiding elder of the Iowa City district. He subsequently accepted the pastorate of a church in Chicago and preached there until the fire of 1871 when he was appointed to superintend the distribution of the relief fund. In this capacity he expended nearly $5,000,000 for the relief of the fire sufferers. The Relief and Aid Society was continued afterward for the benefit of the Chicago poor and Trusdell remained superintendent until his death. He was appointed presiding elder of Chicago in 1885.

TRUSS, *in surgery,* an appliance for the support of a rupture or hernia (q.v.), or for keeping the injured parts in place when reduced. It consists of a pad of wood, hard rubber or other hard material, or of soft rubber filled with water — a water-pad — for compressing the aperture through which the hernia protrudes. In an inguinal hernia this pad is held in place

by a steel-spring band, or some metallic band molded to fit the inequalities of the body, passing wholly or partly about the hips, and assisted by a leather strap. Usually one of two pads are attached to the band posteriorly where pressure is exerted on one or both sides of the spine. A fair temporary truss may be made of a compress of cloth, cotton, oakum, etc., held in place by adhesive plaster and a spica bandage. An umbilical hernia may be kept in place by a pad, strips of adhesive plaster, and a cloth bandage. An ill-fitting, uncomfortable truss does harm.

TRUSS, *in architecture,* a combination of braced timbers, or of steel-work, or of both together, so arranged as to constitute a frame, that resists strains in two or more directions. A trussed beam is one braced against deflection. (For illustrations of trusses, see BRIDGE). The simplest example of a truss is the principal or main couple of a roof, in which the tie-beam is suspended in the middle by the king-post to the apex of the angle formed by the meeting of the rafters.

TRUSS BRIDGES. See BRIDGE CONSTRUCTION, MODERN METHODS OF.

TRUST COMPANIES. See BANKS AND BANKING — TRUST COMPANY.

TRUSTEE, *in law,* a person to whom property is legally committed in trust, to be applied either for the benefit of specified individuals or for public uses. The person for whom or in whose favor the trustee holds the estate, or any interest therein, is called the *cestui que trust.* Trusts are generally raised by marriage settlements or by wills. The ordinary trusts in the former case, as to real estate, are, in the first place, for securing to the wife payment of her pin-money during marriage, and of her jointure on her becoming a widow; then for raising the stipulated provisions for younger children, and also for providing for their maintenance while minors. Trusts are commonly raised in wills for the maintenance or advancement and portioning of children. Trustees may be declared verbally as regards personal estate, but as to land, writing is necessary. No one is compelled to undertake a trust, but if he once accept he cannot renounce it unless the trust-deed contains a provision enabling him to do so, or by the consent of all those beneficially interested in the estate. Trustees are bound to act in strict accordance with the terms of the trust, and are liable for the consequences of any breach of trust. However, courts may relieve a trustee from personal liability, either wholly or partly, if he has acted honestly and reasonably. They are accountable for the interest which they do or might make from the employment of the money in their possession, as also for the whole profits they may derive from trading with the trust fund. As their office is considered purely honorary, they are not entitled to any allowance for their trouble in connection with the trust. Trustees are liable for any misapplication of the trust fund arising either from ignorance of facts which they might by common diligence have known, or from ignorance of the law in any case, even though they may have acted in good faith and in reliance on the opinion of eminent legal advisers; but they may apply for advice by petition to a judge or by summons to a judge, and so be absolved from responsibility. The estates of trustees deceased are liable in the case of fraudulent administration. The appropriation of the trust fund by the trustee to his own use makes him liable to prosecution and punishment by imprisonment. There is a growing tendency to leave such trusteeships to trust companies.

TRUSTS. I. An economic unit is an aggregate of land, labor and capital united together by more or less permanent bonds and operating under the guidance of some directing mind or minds. Economic units differ in size, in the character of the work done and in the relative amount of the co-operating elements employed, but all are alike in one respect, viz., all are destroying natural resources and using up human energy in order to produce commodities and services necessary for human existence or human pleasure. Under the capitalistic system, each economic unit is controlled and directed by certain persons called proprietors, who, generally speaking, own the land, hire the labor and reap the benefits that arise from producing the commodities or services at less than the costs incurred. Under such circumstances, the proprietors naturally try to form economic units of such size and such character as to secure a minimum of costs for a given benefit or a maximum of benefits for a given cost or costs. In this connection, three facts should be borne in mind; first, it is always much easier to form and to operate small economic units than large ones; second, in certain kinds of work, larger units are necessary, in many kinds, the larger units are more productive and therefore more profitable for their proprietors; third, economic units may be united into compound economic units, or systems, of such size and character that all or nearly all the advantages which might have been obtained by the creation of large size units at the outset are gained by the process of uniting or amalgamating existing economic units at any time after their formation. In view of the above conditions it is not only natural but in most cases extremely desirable that proprietors should start out in a modest way, compare costs and results in the small and large units operating in the same particular field and attempt to adjust the size of the operating units according as the small or large are found to be more productive.

An increase in the size of the units and in the scale of the operations may be secured either by adding more land, labor and capital to existing units or by uniting existing units into systems as above stated. The former process secures the requisite size by growth, the latter by union. Generally speaking, wherever conditions have changed in such a way that the larger units possess advantages over the smaller ones, both processes are going on side by side, some proprietors employing one, others the other, the choice being determined partly by the mental and moral characteristics of the proprietors, partly by the peculiar conditions of the industry in which the transition from small scale to larger scale production is economically demanded. Whatever the conditions in the industry and whatever the character of the proprietor, the process of securing the *readjustment* of size by growth is accompanied by con-

sequences of which the proprietors as a class are cognizant. To convert all of the small economic units into large units is of course impossible except in a very rapidly growing field. Some of the economic units must therefore remain small, and smallness under such circumstances means economic death. To avoid such disastrous consequences the proprietors may prefer to join together into unions, thus securing certain of the advantages of size without at the same time facing a competitive struggle that must inevitably result in the complete annihilation of those units that for any reason are left behind. The unions thus formed may be composed of any number of economic units from two to the total number in existence. Unions composed of a relatively small number of economic units are co-operative agencies for performing in common certain functions that otherwise would have been performed by each member separately. They, therefore, are institutions possessing distinct economic advantages to society by reason of their efficiency and also by reason of the competition which they foster and preserve. Unions composed of a large number of economic units, while possessing the advantages that grow out of co-operative action, may gain by virtue of the union a very different kind of power, viz., the power of monopolistic control over the goods and services which they respectively produce. In the latter case the organizations thus created are enabled not only to retain for the proprietors all the benefits arising from the co-operative action which follows, but further to gain an additional advantage in the enhanced price which they are in a position to obtain for their goods and services.

II. The simplest form of union is one in which the proprietors secure concerted action along some one or more lines by a simple agreement, providing for uniform action upon certain stipulated points or for the sharing of privileges or benefits that flow either directly or indirectly from the union.[1] Agreements providing for uniform action upon one or more specified points are called simple combinations; those providing for a sharing of benefits are called pooling combinations, or in the vernacular of the trade, pools. Combinations may be compared to a league of nations in that each member retains its independence in full except as it temporarily surrenders a portion of its sovereignty in the interests of the common good for a limited period of time and even then subject to withdrawal on notice or without notice at the risk of suffering certain specified or contingent penalties. Simple combinations embrace the following types of agreements: first, those limiting the territory within which the several parties may do business; second, those limiting the amount of business which may be done; third, those fixing the price at which each may sell its goods or services. Pooling combinations include: first, agreements providing for a distribution of the business in certain agreed upon proportions, and second, those providing for a sharing of the profits arising from the business over which the pool has jurisdiction. Combinations and pools may also be classified into various categories on the basis of the number of specific agreements included within the union, as for example, simplex, duplex, triplex, quadruplex, etc.[2] A simplex combination is based upon an agreement as to one point only, as price, or output. A duplex combination is based upon an agreement that covers two important features, as price and output, or price and percentage of business. As the number of points which the agreement covers increases, the field within which the members are free to act upon their own motion correspondingly diminishes and if in any case all possible points are included, the combination during the period of the agreement would be to all intents and purposes a single economic unit occupying the field formerly covered by its constituent members.

III. The higher types of union differ from the simpler types in two respects: first, all of the proprietors' interests in the several economic units are amalgamated or merged into one completely or nearly completely unified organization; and, second, they generally are permanent institutions. Such institutions may be separated into two main classes, first, federated unions and second, centralized unions. The federated unions embrace two classes, trusts and holding combinations. The centralized unions include one class only, viz., the single corporation owning directly the various plants and properties which formerly were separate economic entities. The trust, the holding corporation and the single corporation composed of an aggregate of formerly independent economic units are financial unions in contradistinction with the combinations which are merely incomplete operating unions.

IV. A combination is formed by agreement of the parties and like any contract may be either verbal or written. A financial union on the other hand involves a purchase and a sale either of securities or physical assets and consequently the formation of such an organization includes first, an agreement as to the terms of the exchange and second, provision for the transference of the several proprietors' interests to a newly created body legally authorized to purchase and hold the same. Let it be supposed that *A*, *B* and *C* are proprietors of business enterprises manufacturing and selling safety razors. After selling their different products in competition for some years, *A* conceives the idea that an agreement as to prices at which each may sell his goods would, by preventing price competition, enable each of the razor makers to increase his own earnings. *A* therefore suggests a meeting and after a discussion, supplemented in many cases by an investigation of costs and the actual prices obtained for their respective goods, an agreement is reached and a memorandum covering the points agreed upon is drawn up and signed or a verbal contract is entered into according as the combination is a written or verbal one. After the combination is formed, the parties

[1] These agreements may provide means and measures for their own enforcement, may inflict penalties for infraction of their terms, or may leave the observance of their various stipulations to the good faith of the several members. In the latter case the combinations thus formed and operated are termed gentlemen's agreements.

[2] Stevens, 'A Classification of Pools and Combinations based upon American Experience' (*American Economic Review*, Vol. III, No. 3, pp. 545-575).

separate and proceed to manage their separate business enterprises as before except that each of the proprietors causes a new price list to be prepared and issues instruction to his sales managers to sell goods only at the prices thus established. Whenever any one of the parties to the combination desires to change the price list, a meeting of the principals or their agents becomes necessary at which the whole question of price is taken up and a decision reached either to abide by the old price list, to establish a new one or failing an agreement on one of the above points to terminate the agreement and resume the former power of price making by individual action. The combination is then by virtue of its structure both incomplete in its scope of action and unstable in point of time. It, therefore, may be used only when the above features are relatively unimportant. To secure either permanency or completeness or both some form of financial union, that is either a trust, a holding corporation or a single corporation must be selected and adopted.

To create a trust any number of business units as for example, a, b, c, d, etc., transform their individual business establishments into corporations,[1] formed upon similar plans. They then organize each of the new corporations and thereafter call a meeting of the representatives of the several business units that desire to enter the trust for the purpose of formulating a plan of union. To do this a trust deed[2] is drawn up, a document similar to a corporate charter in its essential features, but peculiar in that it provides (1) that the common stock of the several corporations included in the plan be exchanged for trust certificates and (2) that the trustees (a) manage the several corporations "in the manner they deem most conducive to the best interests of the holders of said trust certificates"[3] and (b) receive all interest and dividends declared upon and paid upon the bonds and stocks which they hold in trust and distribute such receipts including also any receipts from the sale of the trust property by declaring and paying dividends upon the outstanding trust certificates. A trust, then, is a group of corporations tied together into a permanent financial union in accordance with the terms of a trust deed and operating under the control of a board of trustees created and acting under the authority of the said instrument. To make the above definition conform to the conditions which were present in all of the trusts established during the decade 1879–88, two others must be added, viz. (1) that the corporations thus joined together must be competing with each other at the time of the union and (2) that practically all of the producing units in the same market must be included in the organization.

The first of the industrial trusts was formed in 1879 by the Standard Oil interests under the guiding genius of Mr. S. C. T. Dodd, later vice-president and general counsel of that unusual aggregation of properties and brains. The trust, a unique form of federated union, was invented in order to secure centralized administration without at the same time obliterating the corporate identity of the several units of which the organization was composed. The success of the Standard Oil Trust was so pronounced that it was very soon copied and within the decade immediately following, a half dozen other trusts were formed[4] and began operation. The career of the trust as an individual organization was, however, short-lived, two of the leading examples, the Sugar Trust in New York[5] and the Standard Oil Trust in Ohio,[6] being declared illegal organizations on two grounds, first, because it was beyond the power of corporations, either directly or indirectly, to enter into partnerships with other corporations and second, because it was illegal to form monopolies. As a result of the two decisions above referred to it became evident that either the federated form of financial union must be abandoned or some substitute invented or discovered. Fortunately for the trust institutions, the path was open. As early as 1833,[7] the Baltimore and Ohio Railroad Company was authorized by the State of Maryland to purchase the unsold portion of the stock of the Washington Branch Road, provided a majority of the stockholders should vote in favor of the said purchase. In due time their consent was obtained and for over 66 years the stock in the Washington Branch Road was carried as an asset in the balance sheet of the parent company. Beginning about 1850 the practice became common among the railways[8] and later was adopted by the Western Union Telegraph Company and various other industrial corporations. The stockholding method of uniting corporations was thus well known among financiers when the trust was declared illegal and would have been immediately adopted by the various trusts except for the fact that at that time express authority must generally be obtained from some legislature[9] and naturally legislatures were not inclined to grant the requisite authority where monopolies might thus be created or maintained. At this juncture the State of New Jersey amended her general corporate law by adding a clause providing that corporations incorporated under her laws might, with certain exceptions, hold stock in other corporations whenever such power was deemed desirable by the board of directors and the right to do so was expressly stated in the articles of a corporation.[10] Soon thereafter the American Sugar Company, which after the dissolution of the trust had purchased the assets of the various subsidiary corporations, purchased the stock of several Philadelphia refineries and in a leading case the purchase was held to be legal under the Sherman Anti-Trust Act.[11] The holding corporation thus having been authorized by one

[1] Unless the existing business units are already corporations, in which case the existing organizations are used.

of the States and one such organization approved by the highest court, this form of federated union was generally adopted by all the greater aggregations of capital from 1894 on for the next decade. During the period 1894–1904, the new form of federated union was so extensively used by the railways and the industrial corporations that the holding corporation threatened to serve as the tool of well-nigh universal monopoly and on this account the economic literature of the period was largely devoted to a discussion of the growth, development and dangers of the new type of trust.

Curiously enough the turning point came in connection with the creation of a holding corporation uniting two of the greater railway systems. In 1900, Mr. James J. Hill, desiring to consolidate into a more permanent union the vast railway interests of which he was the head, projected a holding company to unite the various railways known as the Great Northern system, and in connection with this scheme the proposal was made to include the North Pacific in the new organization. After a memorable contest in which the Harriman interests played a spectacular part, the project was perfected, the Northern Securities Company was incorporated 12 Nov. 1901 and shortly thereafter the new corporation acquired by exchange of its stock a large majority of the stock of both the Northern Pacific and the Great Northern Railway companies. This union aroused marked antagonism in the Northwestern States and as a result, early in 1902, suits were brought by both the State of Minnesota and the United States for the purpose of securing the dissolution of the Northern Securities Company as an illegal trust under the Federal Anti-Trust Law, and after a notable legal contest, the Supreme Court held the new company an illegal combination and consequently enjoined it from voting the stock in the two companies and from exercising any control over the companies whose stock it held.[1] As a result of this decision, the Northern Securities Company as a holding corporation was dissolved and this type of union was thereafter considered to be of doubtful legality except in those cases when no monopoly was obtained by its means. The decision in the Northern Securities case was later sustained and extended to cover consolidations composed of manufacturing companies by those rendered in the Standard Oil[2] and Tobacco[3] cases in 1911.

Although the single corporation has been used at intervals throughout its history[4] as an agency for uniting independent business establishments into more or less completely consolidated financial unions, such use was of small importance before 1890 and even since then the federated union has been more widely patronized.[5] While the space available for this article is too limited to go into details, it may nevertheless be pointed out that in the beginning of its history the Standard Oil Company made extensive use of this device and it was only when this corporation began extending its scope so as to include pipe-lines and other allied interests whose identity it was desired to preserve that the trust and the holding corporation form became the favored instrument of consolidation. In the later history of the trust movement two cases may be mentioned. When in 1891 the Sugar Trust was dissolved as a result of the court decisions, a new corporation, the American Sugar Refining Company, was organized and it proceeded to purchase the properties which the trust had formerly controlled.[6] During the later period of consolidation the International Harvester Company has been the most important aggregation to make use of the single corporation as a means of uniting a group of allied business enterprises. This union was formed in 1902[7] and in 1912 the United States filed a petition[8] in the District Court, district of Minnesota, alleging that the single corporation thus formed was a monopoly and asking that the combination be decreed to be in restraint of trade and a monopoly under the Anti-Trust Act of 1890. Here then we have a case presented for adjudication[9] in which the union is neither in the form of a combination, a trust, a holding corporation, but in the form of a consolidation consummated by the purchase by a single corporation of the tangible properties of competing economic units.

The language of the Sherman Anti-Trust Act is seemingly as comprehensive as possible. "Every contract, combination in the form of trust or otherwise, or conspiracy, in restraint of trade or commerce among the several States or with foreign nations" is declared to be illegal. But the language of a statute must be interpreted by the courts before its meaning is certain and the Sherman act is not an exception. For the first two decades of its history it was strongly asserted by counsel for various combinations that the combining of competitive units by purchase[10] was not prohibited no matter what the effect upon competition, since otherwise Congress would have intended to place a limit upon the acquisition of property. It was early intimated by the Supreme Court that this contention would not be sustained wherever the effect of sustaining it would mean the nullification of the act. Thus as early as 1905

[4] Consult Scott's Joint Stock Companies to 1720, for early instances.
[5] "In the case of the newer combinations in the United States it has been found that practically all the important ones are put into the form of a single large corporation. In many cases the new corporation buys the individual plants which it seems desirable to combine and thus becomes a single owner of all the establishments.
In other cases, and this is perhaps especially true with reference to the largest combinations, the stock of the constituent members is all bought by the single unifying company, the constituent companies then retain their organization intact, being controlled simply by this central corporation, as a stockholder, which can elect directors and officers at will and thus guide the management absolutely." Report of Ind. Com., p. vii.
[6] This same method was used by the United States Rubber Company, the National Cordage Company and its successor, the Standard Rope and Twine Company, the National Wall Paper Company, and indeed by a considerable number of the great consolidations formed immediately after the trust was declared illegal.

it was stated that the "possession of the power, which if exercised, would prevent competition, brought the case (the Northern Securities) within the statute, no matter what the nature of the title was."[1] The view here indicated in a general way was confirmed and made so specific that all reasonable doubt as to the attitude of the Supreme Court toward the meaning of the first clause of the act was removed by the language used in the Standard Oil case of 1911[2] and later in the Tobacco[3] and Union Pacific[4] cases. In the former case, in a passage which was devoted specifically to an examination of the first and second sections of the act with a view to determining their meaning, it was stated "that in view of the many new forms of contracts and combinations which were being evolved from existing economic conditions, it was deemed essential by an all-embracing enumeration to make sure that no form of contract or combination by which an undue restraint of interstate or foreign commerce was brought about could save such restraint from condemnation," and "undoubtedly, the words 'to monopolize' and 'monopolize' as used in the section reach every act bringing about the prohibited results." This judicial interpretation of the meaning of the first two sections of the act, growing out of the adoption of the "rule of reason," adopted in the Standard Oil decision of 1911, reaffirmed and made even more specific as to the purchase of either properties[5] or stocks,[6] has made the single corporation which has established a monopoly by the purchases of the various necessary properties, an illegal combination in restraint of trade and, therefore, subject to all the pains and penalties of the anti-trust law. The adoption of the rule of reason by the Supreme Court, it should be noted, has accomplished two desirable results. In the first place it has made the formation of monopolies illegal whatever the method or device adopted, and in the second place, by placing the emphasis upon results rather than on form, it has removed the ban upon the formation of financial unions of related enterprises when such union does not result in the establishment of consolidations of monopolistic power. Proprietors of small economic units are thus free to combine for the purpose of gaining the advantages of large scale operation provided they stop the process of combination before monopoly powers are gained. The proprietors thus gain the advantages of more economical production and at the same time the major portion of such advantages accrue to the consuming public by reason of the fairer and more normal competition which necessarily follows.

TRUSTS, THE GROWTH AND CONTROL OF. Magnitude of the Trusts.— In 1904, 'Moody's Manual of Corporation Statistics,' 'The Truth about Trusts,' and other cognate works, stated that there were seven greater industrial trusts in the United States having an aggregate capitalization in stocks and bonds of a par value of $2,662,752,100, and controlling over 1,500 subsidiary plants, and 298 lesser industrial combinations with a total capitalization of $4,055,039,433, and controlling over 3,400 subsidiaries. Adding various reorganized trusts, the aggregate capitalization outstanding in the hands of the public of 318 important and active industrial trusts at that time was no less than $7,246,342,533, representing in all consolidations of nearly 5,300 distinct plants, covering practically every line of productive industry in the United States. Mr. Moody also gave details of over 1,500 distinct corporations, of which 251 had a capitalization of $6,905,700,000, and 410 had a total floating capital of $20,379,162,511. The United States Steel Corporation, the largest of all, with its numerous subsidiaries, represented $1,703,168,118 of this aggregate capitalization. Under date of 11 Sept. 1912, Albert H. Walker, author of 'History of the Sherman Law,' in 'President Taft and the Sherman Law,' noted that from the beginning of the Taft administration to that date, among 62 prosecutions begun under the Sherman law, the only cases that developed any hope of a general public benefit were those of the following companies: Standard Oil, American Tobacco, Du Pont Powder, Electric Lamp, Standard Sanitary, Wire Pool, Sugar Refining, Shoe Machinery, United States Steel, Cash Register and International Harvester. He also gave a list of 50 holding companies that had not been disturbed "in their regular business of violating the Sherman law throughout the administration of President Taft." These holding companies had a capitalization of over $2,300,000,000, and controlled more than 700 subsidiary corporations. Further, he declared: "I can furnish a list of more than 950 other industrial holding companies which have an aggregate capitalization of more than five thousand million dollars, with more than 6,000 subsidiary corporations."

Sherman Anti-Trust Law.— This act of Congress, originally proposed and outlined by John Sherman, when United States senator from Ohio, was perfected by the Judiciary Committee of the United States Senate, enacted by Congress, and approved by the President on 2 July 1900. That committee comprised Senators George F. Edmunds, chairman (Vermont), John J. Ingalls (Kansas), George F. Hoar (Massachusetts), James F. Wilson (Iowa), William M. Evarts (New York), James L. Pugh (Alabama), Richard Coke (Texas), George G. Vest (Missouri), and James Z. George (Mississippi). There has since been an animated controversy on the question of the authorship of the law, which has continued to bear Senator Sherman's name. The most prominent discussions were by Senator George F. Hoar, in his 'Autobiography,' Senator John B. Foraker, Albert H. Walker, Francis E. Leupp, in a contribution to *The Outlook*, and Senator Edmunds, in an analytical contribution, and George Harvey, in an historical 'Foreword,' both in *The North American Review* (December 1911). Senator Hoar, a year before his death, claimed the authorship of the law. Judge Edmunds declared that while the law bears the name of Senator Sherman that gentleman merely introduced a bill of which only the enacting clause, as first drawn, was retained by Congress, and that the law as it now stands was drafted by himself as chairman of the Committee. Further, he stated: "It would be correct to say that nearly every member of the Committee was the author of that bill, for my work in drawing it up was merely putting into logical shape what every member of the Committee had participated in." It may here be stated that the precise work of each member of the Committee has now been clearly established by the official records. Also that since the law has practically broken down in its operation, nobody is very particular as to who fathered it.

In framing the law the Judiciary Committee believed that the well-known principles guiding the courts in the application and construction of statutes would lead them to give the words of the act a beneficial and remedial rather than an injurious and technical interpretation, one hurtful to any honest trade, as well as out of harmony with the beneficent spirit and policy of the whole act. Nearly 11 years after the passage of the act (1911), Judge Edmunds wrote: "That belief has now, on the whole, been realized. It is believed that no case founded on the act has been finally decided by the courts adversely to the contracts or conduct of parties accused in which such contracts or conduct did not offend against both the letter and the spirit of the act, as well as against the sound public policy underlying both the provisions of the Constitution and the act of Congress touching the subject."

Chief Provisions of the Sherman Law.— The act is divided into eight sections, of which the first and seventh practically embody the spirit of the entire act.

Section 1 recites: "Every contract, combination in the form of trust or otherwise, or conspiracy in restraint of trade or commerce among the several States or with foreign nations is hereby declared to be illegal. Every person who shall make any such contract or engage in any such combination or conspiracy shall be deemed guilty of a misdemeanor, and, on conviction thereof, shall be punished by a fine not exceeding $5,000, or by imprisonment not exceeding one year, or by both said punishments, in the discretion of the court."

Section 7 recites: "Any person who shall be injured in his business or property by any other person or corporation by reason of anything forbidden or declared to be unlawful by this act may sue therefor in any Circuit Court of the United States in the district in which the defendant resides or is found, without respect to the amount in controversy, and shall recover threefold the damages by him sustained, and the costs of suit, including a reasonable attorney's fee."

In view of notable actions instituted by the Federal government it should be noted in connection with the foregoing that section 2 makes it a misdemeanor, punishable as in section 1,

for any person to monopolize or combine or conspire to monopolize any part of the trade or commerce among the several States or with foreign nations; and that section 8 classes corporations and associations with persons wherever the words "person" or "persons" occur in the act.

Notable Prosecutions Under the Sherman Law.—At the close of 1912 the United States government had instituted suits against about 125 corporations for violations of the Sherman law. In a special message to Congress on the trust question, 5 Dec. 1911, President Taft presented a list of 99 suits that had been brought up to 1 Nov. 1911. By administrations these were divided as follows: President Harrison (1889–93) seven; President Cleveland (1893–97) eight; President McKinley (1897–1901) three; President Roosevelt (1901–09) 44; President Taft (1909–11) 37; President Wilson (1913–16) 18. The most notable of these cases in which decisions were rendered favorable to the government were, briefly stated, as follows:

Northern Securities Company: suit brought to restrain the defendant from acquiring in any manner the control of the Great Northern and the Northern Pacific Railway companies, 10 March 1902; petition of the government upheld in Circuit Court, 9 April 1903; decision affirmed by United States Supreme Court, 14 March 1904.

Swift and Company, Chicago: suit brought to restrain alleged beef trust from suppressing competition and maintaining a monopoly in the purchase of livestock and the sale of dressed meats; Circuit Court granted a perpetual injunction, 26 May 1903; United States Supreme Court affirmed it, 30 Jan. 1905.

Armour and Company and others, Chicago: indictments found against various meat-packing companies and individuals, 1 July 1905; all objections decided in favor of the government except certain pleas of immunity based on information given the government; court sustained pleas so far as individual defendants were concerned, but overruled them with respect to the corporations.

Standard Oil Company of New Jersey: suit to dissolve illegal combination instituted 16 Nov. 1906; decree favoring the government filed 20 Nov. 1909; United States Supreme Court affirmed judgment, 15 May 1911.

American Tobacco Company: petition to dissolve illegal combination filed 10 July 1907; decision favoring the government except as to certain foreign corporations rendered 7 Nov. 1908; both sides appealed; United States Supreme Court sustained the government on all points and ordered dissolution, 29 May 1911.

Du Pont de Nemours Company (Powder Trust): petition for dissolution of combination filed 30 July 1907; court ordered dissolution, 21 June 1911.

American Sugar Refining Company: indictment found, 1 July 1909; United States Supreme Court decided defendant's plea of the statute of limitations in favor of the government.

Missouri Pacific and 24 other railway companies: petition to enjoin proposed advance in freight rates in Western Trunk line territory sustained by Interstate Commerce Commission.

Standard Sanitary Manufacturing Company: petition to enjoin the combination from restraining competition and enhancing prices of enamel ware, under cover of a patent licensing arrangement; government sustained, 13 Oct. 1911.

General Electric Company: bill in equity, charging combination in incandescent electric lamps and asking decree for dissolution, filed 3 March 1911; form of dissolution accepted by Circuit Court, 12 Oct. 1911.

United States Steel Corporation: petition for an injunction and dissolution filed 27 Oct. 1911. In June preceding, Herbert Smith Knox, United States Commissioner of Corporations, reported that when the steel corporation was organized in 1901 its tangible assets were worth $682,000,000; that by 31 Dec. 1910, these assets had increased to $1,187,000,000; and that by the latter date the corporation had an aggregate of $1,468,000,000 in outstanding securities. The corporation claimed that its iron ore properties were worth $700,000,000, but the Commissioner believed that $100,000,000 would be a liberal estimate. During the summer of 1911 the affairs of the corporation were put under investigation by a committee of the National House of Representatives, and in May 1912, the taking of testimony in the government's suit for an injunction and dissolution was begun in New York. But the steel trust, after an immense amount of testimony had been taken, secured a decision adverse to the government, from which the government appealed.

Application of the Rule of Reason.—The United States Supreme Court decided in favor of the government in the case of the Standard Oil Company of New Jersey and its subsidiaries on 15 May 1911, and in that of the American Tobacco Company on 29 May following. In each instance the decision was an elaborated review of the case, prepared by Chief Justice Edward D. White. It was held that the corporation was a monopoly in restraint of trade; that it must be dissolved within six months; that corporations whose contracts are not unreasonably restrictive of competition are not affected by the Sherman law. In the American Tobacco decision it was held that the company was a combination in restraint of trade and a monopoly in violation of law; that it had been guilty of intimidation and had shown a clear purpose to stifle competition; that the company must disintegrate and recreate a condition of transacting business not repugnant to the law, under the scrutiny of the Circuit Court; and that, if at the end of six to eight months the component corporations failed to bring themselves into harmony with the law, a receivership and dissolution would follow. This decision affected 65 American corporations, two English corporations, and 29 individual defendants; but none of them appear to have suffered seriously.

After a dozen or more years of litigation it became apparent that the government was not gaining anything for the people by its suits against the trusts. Up to 1918 more than a hundred civil suits and more than a hundred criminal suits had been brought against trusts and trust magnates, and four of these had been aimed at labor unions, doubtless with the quiet backing of some magnates who wanted to find if unions were not

also trusts. The government appeared to win a number of these suits. The great Standard Oil Company was ordered to dissolve, and divided itself into 60 odd companies, and went on as before. The National Cash Register Company was told to change its ways, and some of its officers received jail sentences, but the writer can find no record that any of them were served or that the Standard Oil ever paid that $29,000,000 fine which a certain judge once levied on them. A criminal suit was brought against William Rockefeller, Alexander Cochrane, George F. Baker, Theodore N. Vail and nine other directors of the New York, New Haven and Hartford Railroad Company, to find out whether the looting of some $200,000,000 could be charged to any individuals; but the jury acquitted six and disagreed as to the others. The Corn Products Company was told to give a $50,000 bond for good behavior and so was the National Starch Company. The criminal suit against the Cudahy Packing Company was not pressed; the heads of the concerns constituting the Wire Rope Association and the Rubber Covered Wire Association were fined from $5,000 down to $100 each; the great DuPont concern paid the costs and reorganized; the sugar trust asked that its case be held open until decisions were reached in the Harvester and Steel trust cases; in very many other cases small fines were imposed or the government lost, or the cases were appealed and held up under technicalities.

To strengthen the Sherman law, the Clayton Trust Bill was passed and approved 12 Feb. 1913. This prohibited certain monopolizing contracts, popularly called "tying" contracts, by the use of which the United Shoe Machinery Company especially had built up and held an immense monopoly. (Such contracts absolutely choked off competition.) This law permits any person to sue in any District Court where a trust has an agent, and to recover three times the damage sustained by any violation of the Sherman law, also his attorney's fees. It also aimed to stop interlocking directorates and to check many objectionable practices by corporation officers. Labor unions were expressly exempted from its provisions. Much was expected of this Clayton law, but the United Shoe Machinery Company won its case on the appeal to the United States Supreme Court and writes what contracts it pleases, and the other trusts go merrily on much as they used to. Most of the States passed anti-trust laws of one sort or another, as notably New Jersey, under the Wilson administration; but these laws have been even less effective than the Federal laws, because the State seldom has much jurisdiction over a trust that does business all over the world. The Federal Trade Commission was then created on much the same lines as the Interstate Commerce Commission, and of this body much is hoped. It has headquarters in Washington, and the five commissioners, appointed by the President, receive each $10,000 salaries, no more than three to be of one party. So they seem to be well removed from influence. They began their work late in 1914 and conducted the newsprint, the book paper and the bituminous coal investigations. The International Paper Company was accused of creating a corner in paper early in the war, and the newspapers said they cleared up about $25,000,000 in a few months. For this six of the officials paid fines of $2,500 each. Just as it began to look as if the Federal Trade Commission really might do something to alleviate the evils of trusts, the United States entered the World War, the government took over the railways and various other large manufacturing plants and industries, and investigations ceased. After the war in 1919 the meat-packing interests were being investigated.

The trusts are not the menace to democracy that they have been pictured; they have improved methods and reduced costs in many ways; they have shown that competition is not the life of trade, that it entails much waste; in many lines of endeavor they have built up great businesses legitimately and won success because they deserved it; in other lines, though they monopolized, they now so control everything that it cannot be taken away from them, as there are no other concerns that know how to handle the business. Germany has demonstrated to us that concentration of interests tends to reduce costs and increase efficiency. Their form of monopoly was called the kartell, and in some of them, as the potash and sugar kartells, the government participated. American industry must maintain and improve its efficiency, and big business must continue wherever it handles things better than can groups of small concerns. It appears that we cannot crush the trusts if we would, for the trusts represent both the capital and the brains of American industry. Therefore the trusts must be reformed where they need reforming.

Bibliography.— Consult Bigelow, 'Constitutional Difficulties of Trust Regulation' (1905); Brewster, 'What to do with the Trusts' (1907); Bridge, 'Inside History of the Carnegie Steel Company' (1903); Chicago Conference on Trusts, 'Complete Report' (1900); Clark, 'Control of Trusts' (1901); Collier, 'The Trusts' (1900); Dodd, 'Combinations, their Uses and Abuses' (1894); Dos Passos, 'Commercial Trusts' (1901); Edmunds, 'The Anti-Trust Law' (*North American Review* 1911); Eliot, 'Future of Trade Unionism and Capitalism in a Democracy' (1910); Ely, 'Monopolies and Trusts' (1900); Fay, 'Big Business and Government' (1912); Hadley, 'Railroad Transportation' (1885); Hicks, 'Competitive and Monopoly Price' (1912); Hirst, 'Monopolies, Trusts and Kartells' (1906); Hobson, 'Evolution of Modern Capitalism' (1894); 'Inside View of Trusts' (1900); Holder, 'Trusts, Business, and Us' (1912); Ingalls, 'Slaves to the Trusts' (1908); Interstate Commerce Commission, 'Annual Reports' (1887–1917); Jenks, 'The Trust Problem' (1900); Jennings, 'People and Their Property' (1908); Lloyd, 'Wealth Against Commonwealth' (1894); Macgregor, 'Industrial Combination' (1906); Meade, 'Trust Finance' (1903); Meyer, 'Railway Legislation in the United States' (1902); Montague, 'Rise and Progress of the Standard Oil Company' (1903); 'Trusts of To-day' (1904); Moody, 'The Truth About the Trusts' (1904); Pierce, 'The Tariff and the Trusts' (1907); Ripley, 'Trusts, Pools and Corporations' (1905); Snyder, 'Interstate Commerce Act and

TRUTH, Sojourner, American negro lecturer: b. Ulster County, N. Y., about 1790; d. Battle Creek, Mich., 26 Nov. 1883. She was held in slavery even after its abolition in the State. In 1827 she escaped, discarded the slave name Isabella, and chose the above fanciful appellation — Truth — as the substance of her Message and Sojourner because it was divinely revealed. Though quite illiterate, she spoke with much natural talent on emancipation and other reforms. Consult 'The Narrative of Sojourner Truth' (1884).

TRUTH, The. At the time of his death in 1909, Clyde Fitch was enjoying a British and Continental reputation equal almost to his popularity at home. His psychological study, 'The Truth,' had been widely received; his melodrama, 'The Woman in the Case,' had just been hailed in London. There is no doubt that any estimate of Fitch as a dramatist — his prolific pen turned out over 30 original plays, not counting dramatizations and adaptations from the French and German — must rank as high, in technical vividness and psychological achievement, 'The Girl With the Green Eyes' and 'The Truth,' usually grouped together as his most acute feminine studies. Both were written for the actress, Mrs. Clara Bloodgood; and both were pondered over long before pen was put to paper. As answer to the critics who continually believed Fitch to be a hasty spinner of slight feminine studies, one notes in the dramatist's correspondence that as early as 1894 he was speaking to friends of the "jealousy play" to be written. Eight years later, 'The Girl with the Green Eyes' was finished.

'The Truth' was equally as carefully thought out, and is as incisive in its study of the snares and tragedies of lying, as the former is of jealousy. It was presented in New York, 7 Jan. 1907, and was not a financial success, though it was praised for its distinction of style. From the time, however, it was given in London, at the Comedy Theatre, 6 April 1907, with Miss Marie Tempest as Becky Warder, it was universally praised as a technical triumph of revelatory psychology,— showing logically, relentlessly, yet deftly, how a woman's habit of lying over slight things, that might be explained away, leads to unhappiness and dire tragic ends.

'The Truth' has had a worthy stage history in Germany, Italy, Russia, Hungary and the Scandinavian countries. It was revived by Mr. Winthrop Ames, at the New York Little Theatre, on 11 April 1914.

MONTROSE J. MOSES.

TRUXILLO, troo-hēl'yō. See TRUJILLO.

TRUXTUN, trŭks'tŏn, **Thomas,** American naval officer: b. Long Island, N. Y., 17 Feb. 1755; d. Philadelphia, Pa., 5 May 1822. He was impressed into the British navy in 1767, and in 1776 was offered a commission which he refused in order to enlist in the cause of the colonies. He was appointed lieutenant in the American navy in 1776, and assigned to the *Congress,* equipped and commanded the *Independence* in 1777 and was later in command of the *Mars* with 20 guns. He cruised about the English Channel, greatly damaging the British merchant marine, and in 1781 was appointed to command the *Commerce* with 30 guns. His engagements throughout the war were uniformly successful. After the conclusion of peace he was employed for several years in the West India trade, but in 1798 upon the organization of the United States navy he was appointed one of its six captains and assigned to the frigate *Constellation,* with which, in 1799, he captured, after a severe battle, the powerful French ship *L'Insurgente,* and in 1800 *La Vengéance.* He was made commander of the West India squadron in 1801 with the rank of commodore, and in 1802 was appointed to command the expedition against Tripoli, but he retired from the service in that year. He wrote 'Remarks, Instructions, and Examples relating to Latitude and Longitude, also the Variation of the Compass' (1794).

TRYON, trī'ŏn, **Dwight William,** American painter: b. Hartford, Conn., 13 Aug. 1849. He studied art at Paris under De la Chevreuse, Daubigny and Guillemet and at the Ecole des Beaux-Arts. In 1886 he was appointed director of the Hartford School of Art; subsequently held the chair of art at Smith College, Northampton, Mass., and finally settled in New York. He is well represented in all public collections in America, especially in the National Gallery, Washington, and in the Metropolitan Museum of Art, New York. He has been awarded numerous medals and other testimonials to his skill and success as one of the foremost landscape painters of this country.

TRYON, SIR **George,** English naval officer: b. 4 Jan. 1832; d. off Tripoli, 22 June 1893. He entered the navy in 1848, served in the Crimean War, in 1861 became commander of the *Warrior,* the first British sea-going ironclad, and in 1874–77 commanded the *Raleigh.* He was secretary of the admiralty in 1882–84, became vice-admiral in 1889, in 1891 was appointed to command the Mediterranean station, and in 1893 perished in the flagship *Victoria* in collision with the *Camperdown,* due to his error during naval maneuvers off Tripoli.

TRYON, George Washington, American conchologist: b. Philadelphia, Pa., 20 May 1838; d. there, 5 Feb. 1888. He was educated at the Friends' School of Philadelphia, and in 1865 originated the movement for the construction of the present edifice of the Philadelphia Academy of Natural Sciences. In 1865–71 he was the

editor of the *American Journal of Conchology*. His publications include 'Synopsis of the recent Species of Gastrochænidæ' (1861); 'Monograph of the Order of Pholadacæ' (1862); 'Monograph of Terrestrial Mollusks of the United States' (1865); 'Land and Fresh-Water Shells of North America' (1873); 'American Marine Conchology' (1873); 'Structural and Systematic Conchology' (3 vols., 1882); 'Manual of Conchology' (12 vols., 1879–85), etc.

TRYON, Thomas, English dietist: b. near Cirencester, England, in 1634; d. 1703. He worked at carding wool as a boy and tended sheep until 18, when he drifted to London. At the age of 48 he wrote a series of pamphlets recommending water, bread and fruit as food and drink. His book called 'Health's Grand Preservative' (1682) was republished (1691) as 'The Way to Health' and attracted the attention of Benjamin Franklin.

TRYON, William, British colonial governor in America: b. in Surrey, England, 1729; d. London, 27 Jan. 1788. He served with ability in the British army, arrived in North Carolina as its lieutenant-governor in 1764, succeeded Governor Dobbs on the latter's death in 1765, and in 1771 was made governor of New York. In both colonies he was noteworthy chiefly for the cruelties of his administration. In North Carolina he suppressed the Regulators (q.v.) and displayed much inhumanity toward his prisoners. During the Revolution he led in person expeditions which destroyed the Connecticut towns of Danbury, Fairfield and Norwalk. In 1778 he resigned and went to England, where he became lieutenant-general in 1782.

TRYPANOSOMA, a genus of flagellate Protozoa included in the order Binucleata which are characteristic parasites of vertebrates and insects. Related genera live in the gut of insects but Trypanosoma is parasitic in the blood of vertebrates (except *Tr. equiperdum*). The species are transmitted by blood-sucking insects, especially the biting flies (Glossina), and it is probable that a sexual generation is developed in the insect in alternation with the asexual generation in the vertebrate host.

The species are difficult to characterize and thus far are distinguished only by culture experiments. The number of known forms and of diseases produced by them is rapidly increasing. Among the most important are the following: *Trypanosoma lewisi* from the rat, transmitted by fleas and lice, cosmopolitan, probably not pathogenic. *Tr. brucei* in cattle, horses, mules and wild herbivores, transmitted by Glossina, produces nagaña or tse-tse fly disease. It occurs in Africa south of the Sahara. *Tr. equiperdum,* in horse and ass, transmitted by contact (and by biting flies?) produces dourine. It is endemic in the circum-Mediterranean area and has been introduced into nearly all regions, including North America. *Tr. evansi,* in domestic and wild mammals, transmitted by Stomoxys and Tabanus, produces surra in India, China and the Philippines. *Tr. equinum,* in horses, causes mal de caderas in South America. *Tr. gambiense,* in man, transmitted by Glossina, produces sleeping sickness. It occurs in equatorial Africa (elsewhere by importation).

The most of the diseases named are very severe and recovery is rare so that these parasites rightly rank as the most dangerous known.

HENRY B. WARD.

TRYPETIDÆ, the family of fruit-flies (q.v.).

TRYSA, an old city in southern Lycia. It is interesting as the site of an ancient funeral monument with sculptures derived from Greek models representing famous battle scenes. The sculptures were taken to Vienna in 1883.

TSAR, tsär. See CZAR.

TSARITSYN, tsär-ĭt'zĭn, or **TZARITZIN,** zär-ĭt'zĭn, Russia, in the government of Saratov, on the Volga, 230 miles northwest of Astrakhan. It contains the remnants of old fortifications, a castle, seven churches, a mosque, theatre, schools, banks, etc. It is a railway centre and has numerous factories, machine works, tanneries, brickyards and canneries. It carries on a brisk transit trade in Baku petroleum, corn, timber, fish, salt, wool and meals, in the country included between the Don and Volga rivers. Pop. 100,817.

TSARSKOYE-SELO, tsär-skō'ĭ sā'lō, or **ZARSKOJE-SELO** ("Tsar's Town"), Russia, a town in the government of Petrograd, 14 miles south of the capital, with which it is connected by rail. It was the favorite summer residence of the Imperial family, and was founded by Peter the Great. In 1744 the Empress Elizabeth erected the magnificent palace, which Catherine II decorated at great expense. The principal front is about 1,000 feet long. The interior is gorgeously ornamented, the walls of some of the rooms being covered with amber, mother-of-pearl, jaspers, agates and other precious stones. This palace was not occupied by the Imperial family for many years before the Revolution of 1917. The palace grounds, which are 18 miles in circumstance, are finely laid out, and offer every variety of landscape.

TSCHAIKOWSKY, chī-kŏf'skĭ. See TCHAIKOVSKY.

TSCHERMIGITE, chĕr'mĭ-gīt, native ammonia alum. It occurs at Tschermig, Bohemia, in white, fibrous masses, vitreous in lustre, transparent or translucent, with a hardness of one to two, and a specific gravity of 1.50. It is a hydrous sulphate of aluminum and amonium. It is extensively manufactured from the residues of gas works and is used as a substitute for potash alum.

TSCHUDI, choo'dē, **ÆGIDIUS** or **GILES,** Swiss historian: b. Glarus, 5 Feb. 1505; d. there, 28 Feb. 1572. After receiving an education at Basel, Vienna, and Paris, he traveled for a time and served in the French army, 1536-44. He was the chief magistrate of Glarus in 1558, but on account of his opposition to the Reformation, the spread of which he attempted to suppress by force of arms, was banished in 1562. He was recalled in 1564 and spent his remaining years in arranging historical matter which he had collected. His 'Die uralt wahrhaftig alpisch Rhetia' was published as early as 1538, but his chief works, the 'Schweizerchronik' or 'Chronicon Helvetiorum,' covering the time from 1100 to 1470 and the 'Beschreibung Galliæ Comatæ,' were not printed till

1734–36. Modern research has shown that his historical statements are unreliable.

TSÊNG KI-TSEH, or **MARQUIS TSENG.** Chinese statesman: b. Hunan, 1837; d. 1890. He was appointed Minister to Great Britain and France in 1878, and in 1880 was given an embassy at Saint Petersburg where he negotiated the treaty restoring Kulja to China. In 1885 he negotiated a convention with Great Britain in regard to the opium traffic. In 1886 he returned to Peking and in 1887 was made vice-president of the board of revenue.

TSETSE-FLY, an African gadfly (*Glossina morsitans*), noted for the deadly effect of its bite in many cases on warm-blooded animals, but which is regarded as usually harmless to man. It is about the size of a house-fly, brown, with a few yellow stripes across the abdomen. The symptoms of a bitten animal are at first those of a severe cold; the eyes, nose and mouth begin to run, the body then swells, while emaciation sets in. The harm done does not result from a poison in the mouth of the fly, as formerly supposed, but from the communication to the blood of the victim of a microscopic blood-parasite similar to that of Texas fever, which it has received from a diseased animal and carried to another. Tsetse-flies not themselves infected with parasites are thus harmless. Cattle and other animals which recover from the disease are usually immune, and attain a similar immunity after residing for a time in South Africa. The great dread of this fly formerly entertained has, therefore, proved to be unjustified.

TSIMSHIAN, tsĭm-shē-ān' ("people"), a group of North American Indian tribes, forming the Chimmesyan linguistic stock, residing between the Nass and Skeena rivers, British Columbia, together with the adjacent territory and the islands off the coast. They subsist chiefly on the products of the rivers and the sea, especially salmon and oolachen, the latter furnishing large quantities of oil. They also hunt bear, mountain goats and other large game, the horns of the goats being carved into spoons and ladles which are used in their communal feasts. They also make dug-out canoes, but most of their boats are purchased from the Haidas. Their houses are constructed of immense cedar beams and planks and often are large enough to accommodate a hundred persons, who are presided over by a house chief. Each family and town also has its special chief. The population of the tribes forming the stock is about 3,200, including about 750 forming Duncan's colony at New Metlakahtla on Annette Island, Alaska.

TSINAN-FU, tsē'nän'foo', China, the capital of the province of Shan-tung, situated near the south bank of the Hoang-ho River, 220 miles south of Peking. It covers an area of about 10 square miles, within the earthen wall that surrounds it. There are excellent public buildings, an enormous assembly room, fine temples, an old tower and a Romish cathedral. There is a railway, begun by the Germans and taken over by Japanese capital. Pop. about 250,000.

TSING-TAU, or **TSINGTAO,** China. See KIAO-CHAU; SHANTUNG.

TSITSIHAR, or **CICIKAR,** tsēt-sē-kär', Manchuria, capital of the province of Hilung-Chiang, situated on the Nanni, a branch of the Sungari River, near the Mongolian frontier, 500 miles northwest of Vladivostok. It is an important station on the Eastern Manchurian Railroad, has large fairs and a considerable traffic in furs and grain. Pop. about 30,000.

TSU, an old castle town of Japan, capital of Miye prefecture, on the bay of Ise and connected by railway with Nagoya, 46 miles distant. It has modern buildings and newspapers. Intersected by two rivers, its seaport is at the Iwate river's mouth. It is noted for its manufactures of porcelain, fans and parasols. Nearby is Shirako, famous during nearly a thousand years, for its artistic designs and patterns for textiles, which have been copied all over Japan. Pop. of the prefecture 1,101,573, of the city 47,295.

TSU-SHIMA, tsoo-shē'mä, Japan, an island in the Korea Strait, about midway between Korea and the Japanese island of Iki Shima. It is 50 miles long by 10 miles wide, and divided near the centre by a small sound. It was off this coast that Admiral Togo won the principal naval victory in the war with Russia in 1905. Pop. 38,636.

TSUBA, tsū-bäh, the Japanese sword guard, unlike the early Chinese and European sword guards which were wrought into the blade, was a distinctly separate piece of metal, through which the blade passed. Originally, in prehistoric times, the tsumiba, or "blade-clincher," was heavy, of gilt copper and ovate shape. In its development, securing strength with lightness, it came to be, from the 16th century onward, a work of art also. The tsuba reached the highest expressions of pure design and representation of faith and motive, as well as of imagination, while serving in practical usefulness. It became the focus of Japanese art in metal; thickly colored alloys, silver and gold were made use of to express permanently, on iron, unique artistic conceptions, standard and orthodox symbols, and the complete repertoire of Japan's religious, mythological, poetic and literary lore, as well as personal tastes and preferences. Various schools of designers and workers were developed, whose products the experts easily recognize. Perhaps nothing else of Japanese conception or expression in art excels the tsuba as a revelation of the native mind and characteristic features of Japan's civilization. On the abolition of sword wearing by civilians, in 1871 — optional at first and later compulsory — probably a million blades were thrown on the market to be made into domestic tools or laid away in museums. Their wooden scabbards — most probably an evolution from the Malay original, with its loose case of wood — were often lacquered in characteristic and costly style, but their metal ornaments, especially the guards, were in the main preserved. At once art connoisseurs of Europe and America, perceiving this rich find in the artistic field, became eager collectors, so that the private cabinets and public museums compete eagerly for notable or unique specimens. Consult Okabe-Kakuya, 'Japanese Sword Guards' (Boston 1908).

TSUNG-LI-YAMEN, tsoong' lē' yä'mŭn, the department of foreign affairs in the Imperial Chinese government. It is now superseded. See CHINA.

TU FU, Chinese poet: b. Siangyanfu, about 712; d. 770. He gained the favor of the reigning emperor but had a stormy life until 761 when he was given a post in the Board of Works which he held for six years. His book containing 1,405 compositions was issued in 1059. Consult Giles, H. A., 'History of Chinese Literature' (New York 1901).

TUAM, tū'ạm, Ireland, an ancient town in the county of Galway, Connaught, 126 miles west by north from Dublin. It is the seat of the Roman Catholic archbishop, and of the Anglican bishop of Tuam. Its principal edifices are the Protestant and Roman Catholic cathedrals, the bishop's palaces, the college of Saint Jerlath, for the education of Roman Catholic clergy; the courthouse, national and other schools. The manufactures are confined to canvas and a few coarse linens; there is some trade in grain. Pop. about 3,000.

TUAMOTU, twä-mō'too, or **PAUMOTU** (pow-mō'too) **ISLANDS,** or **LOW ARCHIPELAGO,** Polynesia, a group of islands in the Pacific Ocean, belonging to France, and situated between lat. 14° and 25° S., and between long. 124° and 148° W., south of the Marquesas Islands, and east of the Society Islands. The group consists of about 80 atolls with a combined area of 366 square miles. They are, with a few exceptions, of low coral formation, and the surrounding waters are beset with reefs. Cocoanuts, yams and bread-fruit, and pearl, are about the only products. Pitcairn and Ducie Islands belong to Great Britain; the rest are French, and administered from Tahiti. The group was discovered by Quiros in 1606, and came into the possession of France in 1881. In 1903 a severe storm and flood visited the islands and many of the inhabitants perished. Pop. about 5,000. See FRENCH ESTABLISHMENTS IN OCEANIA.

TUAREGS, too-ä'rĕgz, **TUARICKS,** or **TAWAREK,** a fierce and powerful race of Berber origin, professing to be Mohammedans, but different in their practices, religious and social, from most of the believers in that faith. They are virtually independent, although roaming within the boundaries of several jurisdictions, French, Turkish and Moroccan. The tribe is often predatory, and members of it have been guilty of grave outrages on travelers in the desert. Both men and women are of fine physique, and the women go unveiled, and take part with the men in the public affairs of the tribe. Tuareg is the Arabic name for the tribe. They call themselves Imoshagh. See BERBERS.

TUATARA, too-ạ-tā'rạ, the native name of *Sphenodon punctatum,* a large lizard-like reptile formerly abundant on the mainland of New Zealand, but now restricted to some of the small islands off the coast and probably doomed to total extinction. It is the sole living representative of the order *Rhynchocephalia* and because of its great zoological interest as a relic of that ancient group should be preserved, and, indeed, it is protected by the Colonial government. It is about two to two and one-half feet long, with four strong, five-toed limbs, a loose-fitting scaly skin and a fringed crest extending from the head to the tip of the tail. In color it has olive sides and limbs with minute white specks, beneath yellowish; the spines of the nuchal and dorsal crests yellow, of the caudal brown. The teeth are completely coalesced with the jaws and palate to form two tuberculate ridges on each side posteriorly in the upper jaw, and a very hard polished beak in the front of the mouth. Most interesting skeletal features are the presence of two well-developed post orbital arches in the skull, the firmly-fixed quadrate bone, the long series of abdominal ribs and the presence of separate intercentra between the vertebral bodies. On the roof of the skull in the parietal bones is a conspicuous opening, the seat of the pineal eye, which in this animal reaches a high degree of development, but is shielded from the access of light rays by a heavy curtain of pigment which covers it.

These animals live in burrows which terminate in large chambers lined with grass. Certain species of petrels occupy the tuataras' burrows as nesting sites, and the two are reputed to live peacefully together. During the day the tuatara sleeps in its nest but issues at night to seek its exclusively animal food, which consists of insects, lizards, frogs, small birds, earthworms, etc., or along the seashore of crabs, marine worms and small fishes. They are pugnacious but sluggish creatures, and are very fond of lying in water. Sometime during the summer, from November to January, about a dozen eggs are deposited in a hole in the ground, and there they remain for about 13 months when, during the following summer, they hatch. Consult Howes, 'Transactions Zoological Society of London' (Vol. XV).

TUBA, *in music,* a brass wind instrument of the saxhorn family, the lowest as to pitch in the orchestra; it has five cylinders, and its compass is four octaves. It is utilized, since its introduction by Wagner, as the bass of the trombone choir. Also, a high pressure reed stop of eight-foot pitch on an organ.

TUBAL-CAIN. The son of Lamech and Zillah, and according to Gen. iv, 22, the inventor of the art of working in metals.

TUBBS, Frank Dean, American educator: b. Mexico, N. Y., 9 April 1864. He was graduated from the Ohio Wesleyan University in 1888 and received the degree of A.M. in 1893. From 1889 to 1894 he was professor of natural history at the Mexican Methodist College, Puebla, Mexico, from 1894 to 1897 was president of the South American School of Theology, Mercedes, Argentina, and from 1899 to 1901 was professor of biology and geology at Kansas Wesleyan University. In 1902–07 he was professor of science and in 1903–07 principal of Marion (Ohio) High School. In 1907 he became professor of geology and astronomy at Bates College, Lewiston, Me. In 1910–12 he lectured on science at the Bangor Theological Seminary. Professor Tubbs is author and translator of several works in the Spanish language and is well known as a lecturer on science and travels.

TUBE-WEAVER, a group of spiders (q.v.).

TUBE WELL, or **DRIVEN WELL,** a device for obtaining water from the soil, consisting of an iron pipe of small diameter, pointed at the lower end, and driven vertically down into the earth usually by means similar to those used in driving oil wells, until it pierces a water-bearing stratum. The tube is provided with a number of lateral perforations near its lower end, through which the water can enter it. In some cases the water exists in the soil under a pressure sufficient to cause it to flow up through the tube and out at the top; but more commonly a pump must be applied at the upper end, to draw the water up to the surface. When the well is to be driven to a depth greater than one length of pipe, the tubing is usually constructed in sections, which are united by means of screw connections; new sections being added at the upper end as the sinking of the well proceeds.

TUBER, a shortened, thickened, fleshy, subterranean stem in which the leaves appear as scales with axillary dormant buds, collectively called "eyes" in the potato, and Jerusalem artichoke, which are good examples. Internally they contain starch as a principal component. Tneir office is to act as reservoirs of food and to propagate the species when favorable conditions present. Plants which bear tubers are all perennials.

TUBERACEÆ. See FUNGI.

TUBERCULIN, a culture used to test for the presence of the disease tuberculosis in cattle. Prepared as follows: The attenuated cultures of tubercle bacilli or germs are allowed to grow in broth containing glycerine. After growing for several weeks, the bacilli produce certain toxic or poisonous substances which are soluble in and hence dissolved in the broth. The toxic solution is filtered from the bacilli and becomes the solution tuberculin. The process of manufacture has been subject to much variation. When injected in small quantity into a healthy animal it produces no effect, but if the animal has the disease tuberculosis it causes a decided rise in bodily temperature and hence can be used as a test for that disease. It was originally introduced by Professor Koch of Berlin, and hailed as a cure for consumption, on the principle of vaccination for hydrophobia. It proved ineffective, but is by some deemed useful as a test. Consult Cochrane and Sprawson, 'Guide to the Use of Tuberculin' (1915).

TUBERCULOSIS, an infectious, communicable disease caused by the bacillus of tuberculosis. The bacillus induces the formation of little nodules called tubercles. These tubercles may grow in size through the continued action of the organisms; they may soften, break down and be expelled, leaving behind an ulcer or a cavity; they may become hard by a process of sclerosis; or they may calcify. In addition to the local manifestations the disease produces general symptoms like elevation of the body temperature, increased pulse-rate and loss of weight. It is popularly known under a variety of other names as consumption, phthisis, decline, debility, hectic fever and when localized in a special part or tissue, as Pott's disease or hunchback, scrofula, hip-joint disease, white swelling (tuberculosis of elbow) and lupus (tuberculosis of skin). Contrary to prevalent lay opinion, when properly treated, it is a very curable affection.

Distribution of the Disease, Geographical. — Tuberculosis is the most universal of all diseases. It is found in every part of the world, and has been known from the beginning of history. It was accurately described by Hippocrates (460 B.C.), and by Galen (200 A.D.). It is most prevalent, however, in large cities and especially in overcrowded districts.

Distribution According to Race.— No race is exempt, but some races appear less resistant than others. Indians, when brought into civilization, prove especially susceptible. Among the other races in this country the negroes seem to be the most susceptible with next in order the Irish, while Jews stand at the end of the list. In the general mortality about one-tenth and in the mortality between the ages of 15 and 60 about one-fourth of all deaths are due to it. The number of clinical cases in a community is about 10 times the number of deaths in a year (Rosenau). Eighty per cent of these manifest it in the lungs.

Distribution Among Animals.— Most animals are more or less susceptible. Among domestic animals it is found most frequently in cattle and swine, though sheep and horses are not exempt. Dogs and cats manifest it rarely. It is also found in birds (fowl) and fish. Wild animals in their native haunts seem less susceptible, yet in domestication it is the most common cause of death. Rabbits, guinea-pigs, rats and mice may acquire it. Guinea-pigs are especially susceptible to experimental inoculation and are, therefore, commonly used for this purpose. Though frequent in adult cattle, it is infrequent in calves (Nocard), showing that direct heredity plays no part.

Etiology (Causation).— The actual cause of the disease is the tubercle-bacillus described by Robert Koch in 1882. This is a minute vegetable non-motile organism in the shape of a rod or lead-pencil, measuring about three microns ($\frac{1}{11000}$ of an inch) in length, and about four to six times longer than broad. It is visible only under the higher powers of the microscope, a $\frac{1}{12}$ oil-immersion lens being usually used to study it. Its principal characteristic is its behavior toward aniline dyes. It requires the strongest dyes to stain it, but when stained it holds the dye so tenaciously that exposure even to strong mineral acids for a reasonable time fails to decolorize it. This characteristic furnishes the most ready means for its recognition. It is quite parasitic in nature, growing on but few artificial media, namely, blood-serum, glycerine-agar, bouillon or potato, best on the first. It grows only at the body temperature (37° C.). It is slow in growth, and becomes apparent only from 5 to 14 days after inoculation of the medium. Exposure moist to a temperature of 60° C. for 15 minutes, or boiling, kills it, though freezing has no effect on it. It is killed by direct sunlight within a variable period of time (from 15 minutes on), depending on the season and the character of the medium containing the organism; by diffuse sunlight near a window in a week or two. In growing (either parasitically or without the body) the organism elaborates a chemical product highly poisonous to most animals. It

is this poison circulating in the blood which produces the general symptoms of the disease, such as fever, increased heartbeat, emaciation, etc. Tubercle-bacilli found in different animals differ in their characteristics. The human, bovine, avian and fish varieties have been differentiated. One of the principal points to be noted is the slow propagation of the organisms with the consequent slow development of the disease. The actual infection usually precedes the manifestation of the disease by scarcely ever less than two and frequently as many as 20 years.

Predisposing Causes.— Though the bacillus of tuberculosis is the actual cause of the disease whenever it occurs, other factors require consideration. As wheat will not grow on every soil, so the tubercle-bacillus will not grow in every individual. In fact it would appear that the majority of human beings are quite insusceptible, and that as a rule an overwhelming dose of the organisms repeated frequently for some time is necessary to overcome the resistance. All the conditions necessary to produce susceptibility are unknown, yet it is empirically true (and could be with reason supposed) that any circumstance which tends to lower the general vital resistance decreases the resistance to tuberculosis. Therefore, defective and insufficient food, over-work, worry, chronic alcoholism, surroundings like a damp, dark, overcrowded dwelling, persistent irritation of a somewhat naturally susceptible part of the body, as irritation of the lungs by the constant inhalation of dust (mine-workers, stone-cutters, etc.), previous severe disease like typhoid fever, etc., all tend to increase the susceptibility.

It was thought in the past that the most common cause active in the production of susceptibility was heredity, because the disease manifests itself more commonly in the children of the tuberculous than of the non-tuberculous. Recognizing the communicability of the disease, however, the closeness of the contact after birth easily accounts for this, without it proving them more susceptible. In fact, a strong argument can be deduced to the contrary, namely, that the children of tuberculous parents are less susceptible. Granting the communicability, it is not a surprise that children who are kissed and fondled for years by tuberculous mothers contract it, but it is a surprise if any escape; and if they were more susceptible we would expect them to contract it in such a virulent form that no child of a tuberculous mother would ever reach adult age. The fact is, however, that the majority of children of tuberculous parents never manifest the disease and the ones who do usually manifest it in a very chronic fashion and only after the age of 15. In other words, though these children live in an atmosphere impregnated with the germs, the majority fail to contract it and the remainder resist it for years.

Flick's paper on tuberculosis as a house-disease goes to prove its communicability. He investigated all the houses of the largest, oldest and most thickly populated ward in Philadelphia, and found that the deaths from tuberculosis in that ward were disproportionately large in certain houses. In short, he demonstrated case after case of apparently healthy families moving into a house previously occupied by a tuberculous person with the result that one or more members died of the disease.

Modes of Infection.— There are four possible modes of infection, namely, inoculation, heredity, inhalation and ingestion.

Inoculation.— Villemin's work, supplemented by that of Cohnheim and Salamonson, absolutely established the fact that the disease was inoculable. Inoculation is, however, quite rare as a method of general infection in human beings, and its occurrence is practically limited to special occupations. Inoculation with the production of a strictly limited local lesion is reasonably common on the hands of physicians who do anatomical or post-mortem work (the post-mortem wart, the *leichen*-tubercle of the Germans), of butchers, tanners, etc. Local tubercles have also been produced by piercing the ears for earrings, by tattooing and by washing the clothes of a tuberculous patient. Both local and generalized tuberculosis have been reported as a result of the rite of circumcision, the last step in which is the sucking of the wound.

Heredity.— Up to the time of Villemin this was the generally accepted mode of acquiring the disease, though here and there down the centuries from the time of Galen some one has stood out against it in favor of contagion. Hereditary transmission has been experimentally proven on the lower animals (Gärtner), and occasionally demonstrated in human beings by the finding of tuberculous lesions in the fœtus. These proofs occur so rarely, however, that the ordinary view of practically all cases being examples of contagion, is fully warranted.

Inhalation.—The common belief at the present day is that the majority of cases of tuberculosis are the result of inhalation of the germs. The contagiousness of the disease being proven, and the infectious bacilli being found in the matter given off from a tuberculous ulcer (therefore, in the sputum in tuberculosis of the lungs), it is readily understood how people living with a consumptive may be more or less constantly inhaling the contagion. Nuttall's estimate of the number of bacilli thrown off in the expectoration daily could only make one wonder how anybody escapes the disease, were it not that they are so easily and quickly devitalized. In a case where the patient expectorated about four ounces daily, Nuttall estimated the number of bacilli to be from one and a half to four billions in the 24 hours. Experiments on animals with the dust of rooms occupied by tuberculous patients have usually proven positive (Cornet). The arguments for inhalation as the most common mode of infection are: (1) the very great frequency of tuberculosis of the lungs; (2) the frequency with which all persons are exposed to this form of contagion.

Ingestion.— For years it was thought that tuberculosis of the lungs was the result of inhalation of the germs, and abdominal tuberculosis the result of ingestion with food or otherwise. The argument favoring this view appeared plain; namely, that primary mesenteric gland tuberculosis is almost limited to children, especially the bottle-fed. Living as they do entirely on cows' milk, and considering the susceptibility of horned cattle to tuberculosis, the inference seemed so justified that scarcely any

exception was taken to it. In addition, adults who live as a rule on cooked food scarcely ever show mesenteric gland tuberculosis as a primary infection, but practically always tuberculosis of the lungs, which would readily seem to be the result of contact with the disease in their occupation, sleeping-rooms, etc. This plain view of the matter has, however, undergone a change. The majority of clinicians and pathologists of our day believe that children manifest the mesenteric form more frequently simply because these glands are more susceptible at that age, and adults the pulmonary form for an analogous reason. For several years at the end of the 19th century considerable was written to prove that practically all cases of tuberculosis were the result of ingestion of the germs. It was contended that even in tuberculosis of the lungs the germs entered through the digestive tract, passed into the chyle-vessels with the fat, were carried through the thoracic duct to the heart and took up lodging in the lung on account of its non-resistive power. The experiments about this time demonstrating the infectivity of cows' milk became so numerous (Gerlach, Bang, Bollinger, Ernst) that the question of the digestive tract as a probably common route (if not actually the most common) seemed practically settled. At the British congress on tuberculosis in 1901, however, Koch threw a shell which scattered scientific physicians and left them in two hostile camps. Coming from any one else the opinion (for it was scarcely more than an opinion, being based on a small number of experiments) would have been scoffed at, but coming with Koch's authority it could not fail to arouse interest and even advocates. Koch affirmed that the difference between the bovine tubercle-bacillus (that is, the bacillus causing disease in cattle) and the human tubercle-bacillus was such that one was not contagious to the other species, or was so slightly contagious that the number of cases of tuberculosis thus produced might be left out of consideration without impairing statistics. During the past 18 years the efforts to disprove Koch's statement have been numerous, but the question is not yet absolutely settled. Our investigations are conclusive enough, however, to lead us to believe that about 5 per cent of the cases in human beings are due to the bovine bacillus. Practically all of these are in the lymphatic glands of children, or in other extra pulmonary locations; the number in the lungs of adults is negligible.

Primary and Secondary Infection.— The belief is gradually gaining ground that the ordinary manifest tuberculosis of the lungs is a result not of primary but of secondary infection. Inoculation experiments on animals have always shown primary inoculation to produce tuberculosis of the nearest lymphatic glands with no lesion at the site of inoculation, and secondary inoculation to produce no lesion of the lymphatic glands with definite tuberculosis at the site of inoculation. It would appear, therefore, that pulmonary tuberculosis is the result of secondary rather than primary infection and occurs in one of the following ways: The individual ingests tubercle bacilli, which pass through the intestinal wall without producing a lesion, but cause tuberculosis of the mesenteric, and later the bronchial glands. The disease of the bronchial glands produces stasis of the lymphatic circulation in the lung, with a consequent retrograde flow of lymph, which carries the tubercle bacilli from the glands to the lung tissue. Or after the lymphatic glands have become involved an entirely new infection by inhalation or ingestion produces the pulmonary manifestation. A number of investigators (prominent among them Bushnell) believe that the primary infection practically always occurs in childhood and that adult infection is extremely rare.

Pathology.— When the tubercle bacilli are deposited in a tissue they proceed to multiply. Like other plants in growth, they take from their surroundings the chemical elements necessary. The living cells from which this material is taken die. In addition, the growing bacilli throw off waste products containing a poison (toxin) which kills other cells. We soon, therefore, have the tubercle bacilli in a mass of dead débris. A reaction now occurs on the part of the healthy tissue to prevent extension — the cells of the part multiply, and white blood cells wander in from the blood for the purpose of consuming the organisms. It is this mass of bacilli, débris and new cells which constitutes the tubercle described first by Baillie in 1794, and which is the specific lesion of the disease no matter in what organ it occurs. The débris looks like a soft cheese, and is called caseous material or caseation. The new cells are called epithelioid. Usually a tubercle also shows what we call a giant cell, a cell three to eight times larger than the epithelioid.

The question of the cure of the tubercle seems to depend on whether the epithelioid cells or the tubercle-bacilli obtain the upper hand. If the epithelioid cells are manufactured more rapidly than the tubercle-bacilli destroy them they form a dense wall about the tubercle-bacilli, elongate, become fully formed fibrous connective-tissue cells, thus shutting the bacilli up in a capsule, and the bacilli die, while the caseous material calcifies or is absorbed and replaced by scar-tissue or fibrous tissue. When the amount of fibrous tissue in the lung is large we speak of fibrosis of the lung. If, however, the bacilli are victorious the tubercle may grow larger and, coming in contact with other tubercles, form what is known as a conglomerate tubercle, and so continue until even a whole organ is involved. Again, the caseation may advance so rapidly, especially in the lung, that there is never any sharp demarcation between healthy and diseased tissue. This is generally called diffuse tuberculosis, and in the lungs is known as caseous or tuberculous pneumonia.

Finally, as the tubercle advances, other micro-organisms (particularly streptococci or staphylococci) may gain entrance to the caseous material and break it up. If now the tubercle, in growing, reaches a surface its liquid contents may be expelled, leaving behind an ulcer or a cavity. This happens most frequently in the lungs, and the resultant cavity may be of any size from a pea to that of a whole lobe of the lung.

The cavity is usually within the lung, or if at the margin, is limited by the pleura, which thickens about it. Sometimes, however, it breaks through the pleura, allowing pus into the

pleural cavity, which is called pyothorax or empyema; occasionally both pus and air are admitted producing pyopneumothorax.

When newly formed, tubercles appear to the naked eye as grayish-white or yellowish-white specks about the size of a millet seed, hence the name miliary tubercle. When two or more of these fuse, it is called a conglomerate tubercle. Usually the disease, especially in the lungs, progresses by a small number of tubercles localized in one area running together to form conglomerate tubercles and these again to form a larger mass which we call tuberculous infiltration. Sometimes in non-resisting cases miliary tubercles develop rapidly all through the lung and rarely in many other organs and the individual dies before they become conglomerate. This condition is described as miliary tuberculosis. In growth tubercles destroy the tissue which they replace and even when cure results, they only change to masses of scar tissue; the original tissue never returns.

Lymph-Gland Tuberculosis.— Children are most frequently the victims, and the bronchial, cervical and mesenteric are the glands of predilection. Tuberculosis of the cervical lymph-glands is popularly called scrofula. It is treated in a similar way to chronic tuberculosis of the lungs by rest, fresh air and nourishment, or by the X-ray, which appears to be frequently successful. When the glands break down, surgical interference is usually necessary.

Bone Tuberculosis.— This is likewise most common in children. It may be limited to the medulla or periosteum, and spread from either to the cortical portion, producing necrosis (tuberculous caries). It is most frequent at the joints, especially the hip and the intervertebral. Tuberculosis of the vertebral column is popularly called Pott's disease, or hunchback. It is usually associated with lumbar or psoas abscess. When localized to the vertebræ, cures are frequent. The treatment of Pott's disease and other joint tuberculous disease, like hip-joint disease, is similar to that of chronic tuberculosis of the lungs.

Intestinal Tuberculosis.— The intestines show either a miliary variety (the tubercle lying either beneath the mucous membrane or the peritoneum) or a chronic ulceration. Both forms are usually secondary to tuberculosis elsewhere. Miliary tuberculosis and tuberculous ulcers of the appendix are not uncommon, particularly in advanced tuberculosis of the lungs.

Laryngeal Tuberculosis.— This is manifested commonly by adults as a complication of advanced tuberculosis of the lungs. Its bad reputation, as far as cure is concerned, comes from the fact that it usually occurs only when the tuberculosis of the lungs is so advanced that the individual is incurable on account of the lung condition. When it occurs early in the case or as a primary affection, it is just as curable as tuberculosis elsewhere. The amount of hoarseness or pain does not indicate the seriousness of the condition. A small insignificant closed tubercle between the vocal cords may produce marked hoarseness; a small ulcer on the epiglottis may produce great pain; a large, much more serious ulcer when situated elsewhere may produce neither hoarseness nor pain.

The organs most commonly affected in adults are the lungs; in children, the lymph-glands, bones and joints. The other organs are affected much less frequently, and in about the following order: Intestines, peritoneum, kidneys, meninges, brain, spleen, liver, generative organs, pericardium, heart. Tuberculosis of the skin comes under the head of lupus (q.v.).

Symptoms and Prognosis of Tuberculosis of the Lungs.— It is necessary to differentiate three varieties, acute miliary tuberculosis, acute tuberculous pneumonia and chronic tuberculosis.

Acute Miliary Tuberculosis of the Lungs.—This may begin as a primary or be secondary to an acute or chronic affection elsewhere. It is most common as a termination of a chronic affection of the lungs. It comes on rather rapidly, like the ordinary acute infectious diseases, and is sometimes distinguished from them (especially typhoid fever) with difficulty. There is a loss of appetite, loss of flesh and strength, fever (102° to 104° F.), accelerated pulse, hurried respirations, a brown fissured tongue, delirium, then stupor and death. The duration is from two to four weeks. The prognosis is always grave, though no case of tuberculosis is ever so grave that treatment is surely in vain.

Acute Tuberculous Pneumonia.— This is practically always secondary to a chronic tuberculosis of the lungs. It begins, like lobar (ordinary) pneumonia, with a chill, high fever, rapid pulse, shortness of breath, hemorrhagic sputum, flushed face, and the physical signs of consolidation of parts of the lung. Instead of ending by crisis about the ninth day, like lobar pneumonia, it continues to a fatal termination; or the acute symptoms gradually subside, the diseased area becomes fibrous, and the patient gradually gets well, or approximately so, with a loss of lung-tissue equal to the involvement, which is sometimes an entire lung. The diagnosis is made by the ordinary signs of pneumonia and the tubercle-bacilli in the sputum. The prognosis is very unfavorable; rarely, however, a case recovers sufficiently to lead a useful life for a number of years. The treatment is that of chronic tuberculosis.

Chronic Tuberculosis of the Lungs.— This is what is ordinarily understood by consumption, or tuberculosis of the lungs without qualification. Its symptoms vary with the progress of the disease, and the susceptibility of the individual to the poison (toxin) excreted by the bacillus. The onset is usually insidious, and the disease frequently progresses for 5 to 20 years before the patient recognizes it. The symptoms are often brought out by a «cold» from which the patient seemingly does not recover. Many, therefore, attribute their disease to such a «cold.» The first noticeable symptom is sometimes a hemorrhage or a pleurisy; again, a progressive loss in weight or a slight dry cough, becoming gradually worse. The most important very early symptoms are usually slight fever, especially toward evening (which may or may not be accompanied by a chill), hectic flush, acceleration of the pulse-rate, cough, expectoration, loss in weight, progressive pallor of the skin, night-sweats, indigestion or loss of appetite, vague general pains, and soreness localized in the chest. The one positive

sign of tuberculosis at this stage is the finding of tubercle-bacilli in the sputum. If every lesion were open, that is, in communication with a bronchus, there would be tubercle-bacilli in the sputum from the earliest stages, and the diagnosis would be easy; but many lesions are closed, that is, completely encapsulated, and, therefore, show no bacilli in the sputum. Hence the physician must rely on other signs brought out by careful inspection, palpation, percussion and auscultation of the chest and X-ray examination.

As the disease advances, all the foregoing symptoms are intensified. The pulse-rate becomes more rapid, so that it is evident to the patient in palpitation or shortness of breath, the temperature rises to 102 or more, the loss of weight becomes excessive, frequently reaching one-fourth, sometimes one-third and rarely one-half of the usual weight, the pallor becomes marked, the appetite is completely lost, cough may become almost continuous day and night and of a most racking character, expectoration increases, the feet usually swell and the picture presented is known to everybody. The patient is extremely emaciated, the chest is quite flat, the depressions above and below the clavicles are marked and the scapulæ stand out prominently on the back. Hemorrhage may or may not occur. As a rule there is little or no pain. The lungs themselves possess no sensitive nerves, and it is only the associated pleurisy which occurs at intervals that produces this symptom. Examination by the physician now reveals the signs of extensive solidification. This may extend over one whole lung or over the greater part of both. It may or may not be associated with cavities.

Chronic tuberculosis of the lungs, when diagnosed sufficiently early, and when the personal resistance is good, is a very curable affection. This is proven by the number of cured lesions found at autopsy. It is very conservative to say that 50 per cent of all bodies coming to the autopsy table past the age of 35 (death having been the result of some other disease than tuberculosis of the lungs), show a healed lesion of tuberculosis of the lungs. The present post-mortem and clinical records demonstrate that 75 per cent of cases recover. Moreover, these post-mortem records are absolute; there is no practical question of diagnostic error. In addition, many cases with a lessened resistance can be so improved under judicious treatment that their lives are prolonged in comfort for 10, 20, even 30 years. For the encouragement of those afflicted, it might be stated that according to Jacobson the following appear to have suffered from tuberculosis: Cicero, Milton, Samuel Butler, Pope, Shelley, Hood, Keats, Elizabeth Barrett Browning, Francis Thompson, Goethe, Schiller, Molière, Richelieu, Mérimée, Thoreau, Calvin, Descartes, Locke, Kant, Spinoza, Mozart, Chopin, Paganini, Beaumont, Samuel Johnson, Sterne, DeQuincey, Scott, Jane Austen, Charlotte and Emily Bronte, Stevenson, Balzac, Voltaire, Rousseau, Washington Irving, Hawthorne, Gibbon, Kingsley, Ruskin, Emerson, Cardinal Manning, Raphael, Watteau, Bastien LePage, Marie Bashkirtseff, Cecil Rhodes and Laennec, as well as a large number of present-day physicians, who after developing the disease became tuberculosis experts, like Edward L. Trudeau, Lawrence F. Flick, H. R. M. Landis, Lawrason Brown, A. M. Forster, James Price, Estes Nichols and E. S. Bullock.

Diagnosis.— Only rarely is the diagnosis difficult. The comparison of the autopsy findings with the clinical diagnosis at the Henry Phipps Institute showed the physical signs of Laennec to be practically perfect. In addition, we have as aids the examination of the sputum, the X-ray and the tuberculin test. Of these the physical signs elicited by an expert are the most positive. The sputum may fail to show tubercle bacilli on account of the lesion being closed. The tuberculin test is practically absolute, though it does not tell us in what part of the body the tuberculosis is. It is very useful in the diagnosis of tuberculosis in cattle because we only wish to learn the fact of its existence and are not concerned about its location; but not so useful in human beings in whom we usually wish to learn the nature of a lesion in a particular place. The X-ray in advanced tuberculosis is about as accurate as physical signs, but in early lesions it frequently fails. It is likely that time will make the X-ray more accurate.

Treatment of Chronic Tuberculosis of the Lungs.— There is no known specific for the disease. Koch's tuberculin is used by the minority of physicians and by them only in selected cases. There are at present more than 25 different tuberculins (emulsions and sera) on the market, and almost every discoverer claims his is the only one beneficial. The most that can be said with certainty in regard to the treatment with any of them is that in expert hands in small doses they do no harm. In the hands of inexperience their employment is fraught with danger. Whether tuberculin is used or not, the most careful hygienic régime must be instituted. The disease progresses on account of a lack of resistance in the patient; the object, therefore, is to increase the resisting power. This is accomplished by rest, fresh air and good nourishment. If the disease is active, that is associated with fever, rapid pulse or rapid emaciation, or other serious symptoms, rest in bed is necessary. The patient should remain in bed until the temperature is below 99.6, the pulse below 100, serious symptoms in abeyance and gain in weight is evident. An early favorable case usually requires from two to six weeks rest in bed; advanced cases correspondingly longer. Even when ready to be up all day he should lead a regular life, retiring at a proper hour (before 10 P.M. if an adult), in order to get sufficient rest. He should have nine hours' sleep, must sleep alone and, when possible, in a room alone. The best situation for the room is on the southwest corner of the house. The windows of the sleeping-room should be kept wide open, no matter what the weather. In summer all the windows in the room, and in winter, when the air diffuses much more readily, one window at least, should be wide open. The idea is to make every inhalation one of fresh air. During the day the patient must spend as much time as possible out of doors, yet in summer he must not be in the sun. When the weather is cold he should be comfortably wrapped. It is better to multiply the coverings which are readily removed than underclothes. Patients suspecting lung trouble

frequently come to the physician wearing a chest protector, two or even three undershirts and other clothes. This is not only unnecessary, but probably harmful. The regulation clothes of the kind most comfortable to the patient meet all requirements.

Diet.— Nourishment is most important. If a patient is run down, and he usually is, it is absolutely necessary to build him up. This can be accomplished only by a proper amount of food. Some physicians of repute in tuberculosis advise a general mixed diet with the addition of two to four pints of milk daily. Some push the nourishment; others, like Bushnell, insist that it should not be forced. In regard to nutritive value foodstuffs stand in the following order: Milk, eggs, meat, vegetables, cereals. Contrary to popular opinion potatoes never made anyone fat. An ordinary good diet would be: Breakfast, 7:30 A.M., fruit, two boiled eggs, bread and butter and two glasses of milk; lunch, 9:45 A.M., one glass of milk; dinner, 12:30 P.M., soup, meat (preferably rare roast beef or beefsteak), three kinds of vegetables and a simple dessert, like ice cream or rice pudding; lunch, 3:30 P.M., one glass of milk; supper, 6 P.M., meat or eggs, potatoes or other vegetable, bread and butter and two glasses of milk. The diet found most generally suitable to the great majority of patients at the Sanatorium for Consumptives at White Haven, Pa., is as follows: Breakfast, 7:30 A.M., one and one-half pints of milk, with two raw eggs (the eggs may be broken up in the milk or taken whole) and fruit; lunch, 10 A.M., one pint of milk and one raw egg; dinner, 12:30 P.M., soup, meat, three or four kinds of vegetables and pudding or ice cream; lunch, 3:30 P.M., one pint of milk and one raw egg; supper, 6 P.M., one and one-half pints of milk, two raw eggs and fruit; lunch, 8 P.M. (just before retiring), one-half to one pint of milk. Alcohol (whisky, brandy, wine, etc.), which was at one time much lauded, especially by the laity, is now avoided by experts.

Climate.— Up to recently considerable dependence was placed on climate. Patients who could afford it were advised to betake themselves to the Southwest, and not infrequently those who could not afford it were told to "beat their way." It is still generally believed that a dry climate is more suitable for the cure of the majority of patients; yet no matter what the climate, the patient must carry out the foregoing or a similar line of treatment. It is to be remembered that tuberculosis is a disease of all climes and altitudes; that cases develop in Colorado and New Mexico as well as in Canada, and that cases have been and are being cured in all parts of the world. Some writers, among them many eminent in the specialty of tuberculosis, absolutely deny any influence to climate. This, however, may be affirmed with certainty: that if the removal to another climate entails, or is likely to entail, the least hardship or privation, it is better for the patient to remain at home. Moreover, if the patient is sent away he must be referred to another physician, or to a sanatorium, where he will have a physician's care. To send him away to meet his difficulties and emergencies by himself is an acknowledgment on the part of the physician that he does not know how to treat tuberculosis. Tuberculosis is, at least, as serious a disease as typhoid fever and requires analogous attention to detail. To send a tuberculous patient to a farmhouse or hotel in the country away from medical supervision is similar to instructing the family of a typhoid patient in the régime to be followed without returning to learn if the directions are carried out properly, or if new complications have taken place. In addition, in the hotel or boarding-house the patient is afraid to follow the régime too strictly, fearing that others will recognize his complaint, and he will be asked to leave. Moreover, to send a patient to a farmhouse where his disease is known has no further advantage. In this case the people have usually had tuberculous patients previously and have some ideas relative to the disease. These ideas are frequently wrong, yet wishing the patient well, they endeavor to instruct him. Any sick individual is more or less at the mercy of the well people about him; if they insist on certain things he has not the will-power to resist. He is, therefore, being treated by lay people not a physician.

Sanatoriums.— New sanatoriums for the treatment of tuberculosis are springing up almost every month. They are opening their doors as a result of private enterprise or benefaction or of a municipal crusade against the disease. They serve a three-fold purpose: (1) they gather in consumptives from large centres of population, and so prevent them from acting as a focus of contagion; (2) they instruct the patient how to take care of himself so that he is not a menace to others even when he returns home; (3) they demand a discipline which, if followed out, will in a favorable case cure. As a rule patients do better in sanatoriums than at home. There are a number of satisfactory sanatoriums throughout the United States, especially in the Northeast and Southwest quadrants.

Prevention in Cases of Chronic Tuberculosis of the Lungs.— The contagion is contained in the matter given off from a tuberculous sore. Therefore, in a case of tuberculosis of the lungs it is only necessary to destroy the sputum to prevent contagion to others. The patient should expectorate only into receptacles where the sputum can be properly handled without coming in contact with other things. He should never expectorate into rags or handkerchiefs, but should limit himself to spit-cup and paper napkins. The spit-cup should be made of paper so that it may be burned, or if of china should contain an antiseptic or germicide. Ordinary lye will suffice. The cup should be boiled daily. When coughing, the patient should hold a paper napkin before his mouth. There should be no question of anyone sleeping with the patient. Children are especially susceptible; hence, when the parents are tuberculous, extra care must be exercised. The sick room should be uncarpeted, have no curtains or hangings and contain only the bed, a table, washstand and the necessary two or three chairs. Window shades are permissible. The room should be as open to the sunlight as possible in order to keep up constant disinfection. The patient, however, should not be in the sun. The eating utensils (knives, forks, spoons, cups, saucers, plates and glasses) should

be separate and should be boiled after use. Food of any kind left over should be burned; it must not be given to others, or even to the domestic animals, the cow, dog, pig or cat. The patient's soiled clothes should be handled as little as possible. When a change of clothes, sheets, pillow-cases, wearing apparel takes place, the soiled pieces should be rolled up in a clean sheet and boiled without unrolling. They may then be washed in the usual manner. If the patient is walking about the house, every room that he occupies should be as open as possible. He should not be allowed to make the dining-room or the kitchen his living-room. Nobody should leave the patient's room without washing the hands immediately. Children should not be allowed in the sick-room. If the patient dies, the bed and furniture should be taken outside and washed. Bureau drawers should be scrubbed. The mattress should be sent to a steam-cleaning establishment, or at least the stains on it washed with soap and water. Following this the mattress and furniture should be exposed to the sunlight for at least three or four days. The floor and woodwork of the room should be scrubbed and the room opened as much as possible to the air and sunlight for a week. A good working rule for all infectious diseases is that everything which has come in contact with the patient should be burned or boiled; if neither is feasible, it should be thoroughly scrubbed and exposed to the sunlight.

Campaign against Tuberculosis.— This is one of the most important public health issues of the day, and through it we expect the eradication of the disease. During the last 40 years the death rate of tuberculosis has fallen 50 per cent, due, at least, partly to the public health efforts against it. The prospect is sufficiently bright that every State, municipality and individual should be interested. Every municipality should have hospitals for early and advanced cases, dispensaries for the treatment of the poor, an anti-tuberculosis society for the education of the public and open-air schools for tuberculous children. Anti-spitting laws should be made and enforced. Tuberculosis should be on the list of notifiable diseases. Tuberculosis in cattle should be under administrative control. The individual can aid by voluntary work in connection with a hospital or dispensary, by membership in the anti-tuberculosis society or by donation of funds for the work.

Bibliography.— For scientific treatment of the subject, the following writings may be consulted: Laennec, 'Diseases of the Chest' (1823); Walshe, 'Diseases of the Lungs' (1860); Koch, 'Die Ætiologie der Tuberkulose' (in 'Berliner Klinische Wochenschrift,' No. 15, 1882); and 'Weitere Mittheilungen über der Tuberkulose' (in 'Deutsche Medizinische Wochenschrift,' 1891); and 'Ueber bakteriologische Forschung' ('Verhandlungen des X. Internationalen Medizinischen Congress,' Berlin, 4 Aug. 1890); and 'Relation of Human and Bovine Tuberculosis' (in 'Sixth International Congress on Tuberculosis,' Vol. IV, p. 645, 1908); Smith, 'A Comparative Study of Bovine Tubercle Bacilli and of Human Bacilli from Sputum' (in *Journal of Experimental Medicine*, 1898, III, p. 451); Cornet, 'Verbreitung der Tuberkelbacillen ausserhalb des Körpers' (in 'Zeitschrift für Hygiene,' 1888, Vol. V); Flick, 'A Review of the Cases of Tuberculosis which Terminated in Death in the Fifth Ward of Philadelphia, during the Year 1888' (in Proceedings of the County Medical Association, May 1889); Trudeau, 'The Therapeutic Use of Tuberculin Combined with Sanatorium Treatment of Tuberculosis' (in Transactions of the Second Annual Meeting of the National Association for the Study and Prevention of Tuberculosis, 1906); Hamman and Wolman, 'Tuberculin in Diagnosis and Treatment' (1912); Norris and Landis, 'Diseases of the Chest' (1917); Fishberg, 'Pulmonary Tuberculosis' (1916); Lord, 'Diseases of the Bronchi, Lungs and Pleura' (1915); Pottenger, 'Clinical Tuberculosis' (1917); Brown, 'Symptoms, Diagnosis, Prophylaxis and Treatment of Tuberculosis' (in 'Osler's Modern Medicine,' 1913); Bushnell, 'Manifest Pulmonary Tuberculosis (in *Military Surgeon*, April 1918); Barjon, 'Radio-Diagnosis of Pleuro-Pulmonary Affections' (tr. by Honeii, 1918); Dunham, 'Manual of the Roentgenological Examination of the Chest' (in *American Review of Tuberculosis*, November 1918); Walsh, 'Tuberculosis Work in Europe' (in Bulletin Johns Hopkins Hospital, 1906), and 'Folly of Sending Tuberculous Patients away from Medical Supervision' (in *Journal of the American Medical Association*, 3 June 1911), and 'Pregnancy in Cases of Tuberculosis of the Lungs' (in *American Journal of Obstetrics*, LXXVII, 1918); Walsh, Wood and Thompson, 'X-ray Study of Advanced Tuberculosis of the Lungs with Autopsies — The Degrees of Density of General Hospital No. 17' (in Transactions National Tuberculosis Association, 1919); Crowell, 'Tuberculosis Dispensary Method and Procedure' (1916); 'Tuberculosis Directory of Institutions and Associations in the United States' (published by the National Tuberculosis Association).

In general it may be stated that the more the patient learns about tuberculosis the more he will understand the reasons for the directions of the physician and the more likely he is to carry them out. Every patient who can afford it, therefore, should join the National Tuberculosis Association (381 Fourth avenue, New York City), in order to receive the literature accompanying membership. In addition the following popular works are recommended: Flick, 'Crusade against Tuberculosis. Consumption a Curable and Preventable Disease. What a Layman should Know about it' (1903); Knopf, 'Pulmonary Tuberculosis: Its Modern Prophylaxis and the Treatment in Special Institutions and at Home' (1899); Brown, 'Rules for Recovery from Pulmonary Tuberculosis' (1916); Krause, 'Essays on Tuberculosis' (in *Journal of the Outdoor Life*, 1918–19); Carrington, 'Fresh Air and How to Use It' (1912), and 'Living and Sleeping in the Open Air' (1912); Minor, 'Hints and Helps for Tuberculous Patients'; Walsh, 'Onset of Tuberculosis' (in *Journal of the Outdoor Life*, August 1908), and 'Occupations for the Arrested Tuberculous' (in *Spunk*, August 1919); National Tuberculosis Association Standard Pamphlet, 'What you should know about Consumption' (1916); Otis, 'Tuberculosis, Its Cause, Cure and Prevention' (1918); King, 'The Battle with Tuberculosis and How to Win it' (1917); French, 'Home Care of Consumptives' (1916);

Galbreath, 'T. B. Playing the Lone Game of Consumption' (1915); Hawes, 'Consumption, What it is and what to do about it' (1916); 'Nostrums and Quackery' (published by the American Medical Association Press, 1912).

JOSEPH WALSH, A.M., M.D.,
Medical Director, White Haven Sanatorium for Tuberculosis; formerly Commanding Officer, United States Army General Hospital No. 17 (for Tuberculosis).

TUBERCULOSIS, in cattle. See RINDERPEST.

TUBEROSE, tū'bē-rōs or tūb'rōz, an amaryllidaceous garden-flower (*Polianthes tuberosa*). The funnel-shaped perianth, an incurved tube, with somewhat rose-like lobes, often doubled in cultivation, has caused a misunderstanding as to the name, which properly refers to tuberous roots, but is generally pronounced as if it were "tube-rose." The flowers are creamy-white, waxen and brittle in texture, do not fade quickly, and are extremely fragrant, especially toward night. They are borne in a raceme at the top of a slender stem, from two to three feet tall. This stalk springs from a tuft of linear leaves, and is sheathed with the bases of others. The tube-rose is raised from bulbs, which are not hardy in the northern, but are grown for the trade very successfully in the southern, United States.

TUBES, Metal. See PIPE, MANUFACTURE OF.

TUBES, Pneumatic. See PNEUMATIC TUBES.

TUBES OF FORCE, imaginary tubular spaces in a field of force, and especially in a field of electric or magnetic force, whose bounding surfaces may be regarded as made up of lines of force. At any point in the surface of such a tube, the resultant force has a direction that is tangent to the tube. The conception is due to Faraday, and is very useful in forming a mental image of the physical state of a field of force. A tube of force cannot have a free end in any finite region of space. The tube must either return into itself, or pass off to an infinite distance, or terminate upon a mass of matter. The total number of lines of force included within a given tube of force is constant throughout the entire length of the tube; and hence it follows that the total force at all sections of the tube is the same; the intensity of a force varying inversely as the cross-section of the tube. In the case of an isolated electrified sphere, the tubes of electric force are radial cones, which converge, in external space, toward the centre of the sphere, but which terminate upon its surface. Also called "Tubes of Induction." See ELECTRICITY; MAGNETISM; INDUCTION.

TUBIGON, too-bē'gōn, Philippines, pueblo, province of Bohol; on the west coast; 24 miles northeast of Tagbilaran. It is on the coast highway. Pop. 15,860.

TÜBINGEN, tū'bĭng-ĕn, Germany, a town in Würtemberg, on the Neckar, 16 miles south of Stuttgart. The town stands in the midst of diversified scenery and is the seat of a national university. New buildings have been erected in connection with this flourishing institution, comprising various medical and physiological institutes. The university was founded in 1477. The library contains 250,000 volumes. There are a botanical garden and fine scientific museums and collections, and an observatory. Names of celebrities connected with the university are Melanchthon, Reuchlin and Baur. There is trade in agricultural produce, wine and fruits. Its chief history is connected with the 30 Years' War and the Reformation. Pop. 19,076.

TÜBINGEN SCHOOL, a name given to two separate and very different schools of philosophy, because their founders were connected with the famous University of Tübingen. The old school of Tübingen was orthodox. Gottlob Christian Storr, its founder (1746–1805), professor of philosophy at Tübingen in 1775, and professor of theology two years later, accepted without reserve the divine authority of the Scriptures, and defended miracles. Storr severely criticized Kant's book: 'Religion Within the Limits of Pure Reason,' and he set forth his own system in a work called 'Theory of Christian Doctrine Drawn from the Scriptures.' The later or modern school is that of Ferdinand Christian Baur (1792–1860), also professor of theology at Tübingen. Besides attacking the authenticity of certain of the Pauline epistles, he attempted to show that the fourth Gospel was not genuine. He admitted the morality of Christianity, but denied the miracles attributed to Christ and his apostles. Although Baur moderated his tone in later years his teachings promoted the spread of unbelief, and the 'Life of Jesus' by Strauss (1832), which attempted to show the Gospel to be a philosophic myth, was the outcome in a large degree of the critical studies of Baur. In 1915 there were 2,056 students and 128 instructors, but before the war the student body was much larger. Consult Pfleiderer, Otto, 'Development of Theology in Germany since Kant' (London 1890); Nash, H. S., 'The History of the Higher Criticism of the New Testament' (New York 1906); Moore, E. C., 'Outline of the History of Christian Thought since Kant' (1912).

TUBMAN, Harriet, negro abolitionist and philanthropist: b. in slavery about 1815; d. Auburn, N. Y., 10 March 1913. She escaped from her master's plantation in Maryland when about 25 years of age, visited Garrison Brown and other Abolitionists and became an active promoter of the "underground railway." She first rescued her parents and during the two decades before the Civil War made repeated journeys to the South and brought a total of 400 or more of her race to the North and into Canada. During the war she served with the Massachusetts troops as a scout and guided Colonel Montgomery in his memorable expedition into South Carolina. By the friendly help of Secretary Seward she was able to make her home in Auburn, N. Y., after the war, and there soon became engaged in philanthropic service in behalf of the poor and aged of her people. Her efforts led to the Foundation of the Harriet Tubman Home for Indigent Aged Negroes, to which she gave personal oversight until 1908. She married in the South in early life a man named Tubman, who died, and later married Nelson Davis.

TUBUAI, too-boo-ī, or **AUSTRAL ISLANDS,** Polynesia, a group of islands belong-

ing to France, and situated in the Pacific Ocean south of the Society Islands. Combined area, 111 square miles. They are fertile and produce tobacco, bananas and arrow-root. The population is estimated at 2,000, mostly native Polynesians.

TUBULAR BRIDGE. See BRIDGE.

TUBURAN, too-boo'rän, Philippines, pueblo, province of Cebu; on the west coast, on Tañon Strait, 30 miles northwest of Cebu. It is on the west coast highway, and is a place of considerable importance. Pop. 12,570.

TUCKAHOE, an Indian generic name, applied by the eastern Algonquins to all roundish roots. Specifically, it was the name of several Indian foods, as of the golden-club (*Orontium aquaticum*), and the arrow-arum (*Peltandra undulata*), both having deep and fleshy rootstocks, acrid when fresh, but rendered edible by cooking, and abounding in starch. Another tuckahoe was a subterranean fungus (*Dachyma cocos*), found very generally throughout the Southern States in light, loamy soils and growing on old roots, either as a saprophyte or a parasite. In form, size and cortex, it is not unlike a cocoanut, and is white and apparently structureless within, moist and yielding when first dug up, but becomes dry and cracked internally soon afterward. It is also called Indian-bread, Indian-head or Indian loaf, but is without starch, composed largely of pectose, is tasteless and insoluble in water.

TUCKAUBATCHEE, Battle of, in the War of 1812. On 18 Jan. 1814, after the battle of Autossee (q.v.), General Floyd left Fort Mitchell on the Chattahoochee and marched toward Tuckaubatchee, 40 miles south of Emuckfaw. His army consisted of 1,700 men, including 400 friendly Indians, while opposed to him were not more than 2,000 poorly armed warriors. By 27 January he had erected a fortified camp on Calibee Creek seven or eight miles south of Tuckaubatchee and there was unexpectedly attacked by the Indians, who drove in the sentinels and engaged in a fierce conflict within the lines. But the attack was finally repulsed with a loss to the Indians of 37 dead and many wounded while Floyd's loss was 22 killed and 147 wounded. The militia, having had enough Indian fighting, insisted on returning home, wherefore Floyd abandoned all his fortified posts and on 1 February reached the Chattahoochee. Consult Adams, 'The United States' (Vol. VII, pp. 249–250); 'American State Papers, Indian Affairs' (Vol. I, p. 858); Brackenridge, H. M., 'History of the Late War' (pp. 193–194).

TUCKER, tŭk'ẽr, **Abraham,** English philosopher: b. London, 2 Sept. 1705; d. Beckworth, Surrey, 20 Nov. 1774. He studied at Oxford, and later at the Inner Temple in preparation for the bar; but upon the death of his father he retired to his estate near Dorking. In 1754 he began to write his philosophical works, and nine years later published his first treatise, 'Free Will.' The first four of the seven volumes of his most celebrated work, 'The Light of Nature Pursued,' was published in 1768, and the last three posthumously.

TUCKER, Benjamin Ricketson, American anarchist: b. near New Bedford, Mass., 1854. He was educated at the Massachusetts Institute of Technology and in 1877 founded the *Radical Review* which was short lived. He then founded the journal called *Liberty* which in 1881 became one of the leading anarchist papers. Besides translations from leading anarchist writers he published 'State Socialism and Anarchism' (1899).

TUCKER, Charlotte Maria ("A. L. O. E.," that is, A Lady of England), English juvenile writer: b. Barnet, Hertfordshire, 8 May 1821; d. Amritsar, India, 2 Dec. 1893. She began her literary career in 1852 with the publication of 'Claremont Tales' and subsequently published more than 50 books besides numerous short stories. In 1875 she went to India where she engaged in missionary work until her death. Her books are chiefly of an allegorical character and are strongly religious in tone. The proceeds from their sale she devoted principally to her missionary work. Among them are 'Wings and Stings' (1853); 'Old Friends with New Faces' (1858); 'The Lost Jewel' (1868); 'Fairy Frisket' (1874); 'Pride and His Prisoners' (1882); 'Driven Into Exile' (1887); 'Harold's Bride' (1888), etc.

TUCKER, George, American author: b. Bermuda, 1775; d. Sherwood, Ala., 10 April 1861. After graduation at William and Mary College in 1797 he began the practice of law at Lynchburg, Va., and was a member of the State legislature for several years. He became representative in Congress (1819–25), and from that time on was professor of philosophy and political economy in the University of Virginia. He wrote much, including 'A History of the United States.'

TUCKER, Henry Saint George, American jurist: b. Williamsburg, Va., 29 Dec. 1780; d. Winchester, Va., 20 Aug. 1848. After his education at William and Mary College he studied law at Winchester (1802) and served as a private in the War of 1812. He was representative in Congress (1815–19), chancellor of the fourth judicial district (1824–31), judge of the Court of Appeals (1831–41) and professor of law at the University of Virginia (1844–45). He declined the appointment as United States Attorney-General by President Jackson. He published 'Lectures on Natural Law and Government' (1844).

TUCKER, Henry Saint George, American lawyer and scholar: b. Winchester, Va., 1853. He received his education at Washington and Lee University, and practised law at Staunton. He sat in the House of Representatives for eight years, and in 1897 succeeded his father, J. R. Tucker, as professor of constitutional and international law at Washington and Lee. Later he was a dean at what is now George Washington Universlty. He served a year as president of the American Bar Association (1904–05), a post held by his father in 1892–93. He wrote 'Tucker on the Constitution' (1899); 'Limitations on the Treaty-Making Power' (1915); 'Woman Suffrage by Constitutional Amendment' (1916).

TUCKER, John Randolph, American naval officer: b. Alexandria, Va., 31 Jan. 1812; d.

Petersburg, Va., 12 June 1883. He joined the navy in 1826, and during the Mexican War took part in several operations. He resigned in April 1861 and became a commander in the Confederate navy, taking part in the engagements in Hampton Roads, including the conflict between the *Monitor* and the *Merrimac*. He was prominent in the engagement at Drewry's Bluff, and was soon after promoted captain and sent to Charleston, S. C., to command the naval forces. After the fall of that city he went to Virginia and organized the naval brigade, which he commanded until the retreat of the Confederate army from Richmond. He received a commission as rear-admiral in the Peruvian navy in 1866 and directed the combined squadrons of Peru and Chile in their war with Spain. Being made president of the Peruvian hydrographic commission, he instituted explorations and surveys of the head waters of the Amazon.

TUCKER, Josiah, English clergyman: b. Laugharne, Wales, 1711; d. Gloucester, England, 4 Nov. 1799. He was graduated at Oxford, was ordained and appointed curate at Saint Stephens, Bristol (1737) and made rector in 1749. He became dean of Gloucester in 1758. He was noted for his views on the relations of the American colonies to the mother country, holding that separation would be no loss to the latter. His pamphlets on political economy anticipated some of the views of Adam Smith (q.v.). Among his notable utterances were 'The Elements of Commerce and Theory of Taxes' (Bristol 1753) and 'Reflections on Present Matters of Dispute between Great Britain and Ireland' (1775). Consult Clark, W. E., 'Josiah Tucker' (New York 1903).

TUCKER, Nathaniel Beverley, (I), usually known as Beverley Tucker, lawyer and son of Saint George Tucker: b. Williamsburg, Va., 6 Sept. 1784; d. Winchester, Va., 26 Aug. 1851. He was graduated from William and Mary College, Virginia, in 1801, studied law and practised in Virginia until his removal to Missouri in 1815. Here he was circuit judge until his return to Virginia in 1830. In 1834 he became professor of law at William and Mary College and served until his death, 17 years later. He was a prolific writer and has been pronounced the ablest man with his pen of that day in Virginia. Besides many political and miscellaneous essays published in magazines and periodicals, he wrote 'The Partisan Leader: a Tale of the Future' (1836); 'George Balcombe,' a novel (1836); 'Discourse on the Importance of Study of Political Science as a Branch of Academic Education in the United States' (1840); 'Discourse on the Dangers that Threaten the Free Institutions of the United States' (1841); 'Lectures intended to Prepare the Student for the Study of the Constitution of the United States' (1845); 'Principles of Pleading' (1846); and an unfinished life of John Randolph, his half-brother. 'The Partisan Leader,' a prophecy of Civil War between North and South, was reprinted in 1861 by the Republicans under the title 'A Key to the Disunion Conspiracy,' the object being to prove that the Southern leaders had long been planning secession and war.

TUCKER, St. George, American lawyer: b. Port Royal, Bermuda, 10 July 1752; d. Edgewood, Va., 10 Nov. 1827. He came to Virginia in 1771 as a student at William and Mary College, studied law, was admitted to the bar in 1774, and to practice in the general court the following year. He became interested at once in the revolting colonies and in 1781 was commissioned major in the Virginia forces. He was wounded at the battle of Guilford Courthouse and was promoted lieutenant-colonel. He became a delegate to the Annapolis Convention (1786) and professor of law in William and Mary College (1790–1804), after which he sat on the bench as judge for 37 years. He was the author of several poems and dissertations on topics of the day and an annotated edition of Blackstone.

TUCKER, Samuel, American naval officer: b. Marblehead, Mass., 1 Nov. 1747; d. Bremen, Me., 10 March 1833. He ran away to sea in boyhood, in 1768 commanded a merchant vessel plying between Boston and London, and on 17 May 1776 became a captain in the American navy. He settled at Bristol, Me., in 1792, and in 1812 captured a British vessel off the Maine Coast. He was a member of the Massachusetts legislature (1814–18), was one of the framers of the constitution of the new State of Maine (1819) and sat in the Maine legislature 1820–21. Consult Sheppard, 'Life of Commodore Tucker' (1868).

TUCKER, Thomas George, Australian critic and historian: b. Burnham, England, 29 March 1859. On graduation from Cambridge University he became professor of classical and comparative philology at Melbourne University in 1885. He is the author of many critical editions of Greek works. Among his other publications are 'Things Worth Thinking About' (1890); 'Life in Ancient Athens'; 'Life in the Roman World of Nero and Saint Paul'; 'Introduction to the Natural History of Language.'

TUCKER, William Jewett, American college president: b. Griswold, Conn., 13 July 1839. He was graduated at Dartmouth College in 1861, and after completing the course at Andover Theological Seminary, was ordained to the Congregational ministry in 1867, and installed as pastor of the Franklin Street Church, Manchester, N. H. In 1875 he became pastor of the Madison Square Presbyterian Church, New York. From 1880–93 he was Bartlett professor of homiletics at Andover, and from 1893 till his resignation in 1909 he was president of Dartmouth College. He is now president emeritus. His administration was marked by the enlargement and diversification of the curriculum, by the consolidation of the Chandler Scientific School with the College, and by the establishment of the Amos Tuck School of Administration and Finance. The growth of the college in numbers and resources during his administration changed its relative place among New England colleges. He has been Phi Beta Kappa orator at Harvard, Lyman Beecher lecturer at Yale, Morse lecturer at Union Seminary, New York, and lecturer at the Lowell Institute, Boston. He assisted in founding and editing the *Andover Review*, and established the Andover House in Boston, a social settlement, now known as the South End House. His published works include 'From Liberty to Unity' (1892); 'The Making and the Unmaking of the Preacher' (1899); 'Public-Minded-

ness' (1910); 'Personal Power' (1910); 'The Function of the Church in Modern Society' (1911). Since his retirement, on account of impaired health, in 1909, he has taken part in the discussion of public questions, chiefly through articles in the *Atlantic Monthly*. Among these are 'The New Reservation of Time' (Academic Pensions), 'The Progress of the Social Conscience,' 'The Goal of Equality,' 'The Ethical Challenge of the War,' 'The Crux of the Peace Problem.'

TUCKERMAN, tŭk'ẽr-măn, **Bayard,** American author: b. New York, 2 July 1855. He was graduated at Harvard in 1878, studied in Europe, and devoted himself to writing upon literary and historical subjects. He has also been lecturer on English literature at Princeton. His works include 'History of English Prose Fiction' (1882); 'Life of General Lafayette' (1889); 'Diary of Philip Hone' (1889); 'Peter Stuyvesant' (1893); 'William Jay and the Abolition of Slavery' (1893); and 'Philip Schuyler, Major-General in the American Revolution.'

TUCKERMAN, Edward, American botanist: b. Boston, 7 Dec. 1817; d. Amherst, Mass., 15 March 1886. He was graduated at Union College in 1837, and at the Harvard Law School in 1839. After a period of study in Europe he pursued another course at Harvard and later graduated from the Divinity School there. In 1854 he formed a connection with the faculty at Amherst College which lasted till the end of his life. In his earlier years his subject was history, but in 1858 he was transferred to the chair of botany, though he continued as a lecturer on history until 1873. He was the foremost authority in the United States on the subject of lichens. Tuckerman's Glen in the White Mountains was named in his honor. His scientific publications include 'Genera Lichenum: An Arrangement of the North American Lichens' (1872); 'A Catalogue of Plants growing without Cultivation within Thirty Miles of Amherst College' (1875); and 'A Synopsis of North American Lichens, Part I' (1882).

TUCKERMAN, Henry Theodore, American author and critic: b. Boston, 20 April 1813; d. New York, 17 Dec. 1871. He contributed very largely to periodicals, and his writings were at intervals collected. He was best informed on topics of art, and his 'Book of the Artists' is yet valuable for reference. His works include 'The Italian Sketch Book' (1835); 'Isabel; or, Sicily' (1839); 'Rambles and Reveries' (1841); 'Thoughts on the Poets' (1846); 'Artist Life' (1847); 'Characteristics of Literature' (1849–51); 'The Optimist' (1850); 'Poems' (1851); 'Memorial of Horatio Greenough' (1853); 'Bibliographical Essays' (1857); 'Art in America' (1858); 'The Book of the Artists' (1867); 'The Collector: Essays' (1868). He edited with William Smith 'A Smaller History of English and American Literature' (1870). Consult the addresses by Duyckwick (1872) and Bellows (1872).

TUCKERMAN, Joseph, American clergyman and philanthropist: b. Boston, Mass., 18 1778; d. Havana, Cuba, 20 April 1840. He graduated at Harvard in 1798 and was a Unitarian minister in 1801, with a charge at Chelsea, Mass. He there organized the first Seaman's Friend Society. In 1826 he removed to Boston where he successfully took charge of a large organization for co-operative charity. Going abroad, he assisted in the formation of similar work and his plans became a model in France. He was the author of several philanthropic publications. A memoir of his life was written by Channing in 1841.

TUCSON (from the pima *styuk-son,* "black or dark base," in allusion to a stratum in a mountain to the westward), Ariz., city, county-seat of Pima County, on the Santa Cruz River and the Southern Pacific, the El Paso and Southwestern, and other railroads, about 120 miles southeast of Phœnix and 150 miles from the Gulf of California, lat. 32° 14'; long. 110° 54'. Tucson is the largest city in the State of Arizona, and is a mining, agricultural and stock-raising region, and also gains great importance as a resort for those afflicted with pulmonary ailments. Its altitude is 2,390 feet, and owing to the dryness of the climate (the precipitation averaging less than 11 inches per annum) the summer heat is not oppressive, although the temperature frequently rises above 100°, while the climate in winter is delightful. The modern part of the city is well-built and paved and has numerous attractive residences, church edifices, public buildings, hotels and business houses; but the older part of the city bears the appearance of a typical adobe Mexican town of the 17th century. The chief industrial establishments are the shops of the Southern Pacific Railroad, but there are also flour mills, a fibre factory, ice factory, foundry, brick and tile plant, and lumber and stock yards. The Chamber of Commerce enumerates 35 establishments, employing 1,200 wage-earners and 125 salaried employees, and having invested a capital of $2,500,000. Wage-earners receive $1,279,000, and office employees $187,500. It has six excellent banks and two good daily newspapers. It is the seat of a Roman Catholic archbishopric, with a cathedral, and also of the University of Arizona (q.v.); it has a good public school system, several sectarian schools, a Presbyterian boarding school for Indians, and a library housed in a building erected by Andrew Carnegie at a cost of $25,000. Tucson contains a number of churches of various denominations, a Roman Catholic hospital and numerous tuberculosis sanatoria. A Desert Botanical Laboratory has recently been established in the vicinity under the auspices of the Carnegie Institution of Washington.

When first known to history Tucson was a rancheria of mixed Papago, Pima and Sobaipuri Indians, the missionary at San Xavier del Bac, nine miles down the Rio Santa Cruz, beginning to visit it for the purpose of converting the natives in 1763. In 1776 the Spanish presidio at Tubac was removed to Tucson, when it became known as the Presidio de San Augustin del Tuguison. In the early days the surrounding country was overrun and its inhabitants harassed by the Apaches. In September 1848 its population was 760; before the close of the year it was considerably augmented by refugees from Tubac and Tucumcari, who had been driven out by the Apaches, but by 1852 the number of inhabitants had dwindled to 300 or 400. Being within the limits of Gadsden

Purchase (q.v.), Tucson was garrisoned in 1856 by the First dragoons, and on August 29 of that year a convention was held to take measures for a territorial organization of Arizona. From February to May 1862, the city was occupied by Confederate troops, in 1867 the capital was changed from Prescott to Tucson, where it remained until 1877, when it was transferred back to Prescott. (See ARIZONA). The city was incorporated in 1877 and reincorporated in 1883, and adopted a new form of government with a manager in 1915. Pop. 27,553.

TUCUMAN, too-koo-măn', Argentina, the capital of the province of Tucuman, in the northern part of the country, situated near the eastern base of the Andes, on the river Tala, 300 miles northwest of Cordoba. It has a delightful climate, is surrounded by orange groves and sugar plantations, and has a university, a fine cathedral, a large hospital, libraries and a theatre, excellent banking facilities and good newspapers. The chief industrial establishments are sugar factories, distilleries and tanneries. It is an old city, founded by the Spanish in 1565. During recent years it has grown very rapidly, becoming a centre for several railroad lines to Santa Fé, Rosario, Buenos Aires, Córdoba and Salta, and is the principal trade centre of northern Argentina. The area of the province is 10,422 square miles, the population about 333,000; of the city 100,080.

TUCUMCARI, N. Mex., city and county-seat of Quay County, on the Chicago, Rock Island and Pacific and the El Paso and South Western railroads, about 350 miles southwest of Denver. It has a government experiment farm and a city library and is a distributing point for coal. It is interested in cattle raising, wheat and corn growing and the manufacture of sisal. Pop. about 3,000.

TUDOR, tū'dor, one of the royal families of England, having a representative on the throne from 1485 to 1603. The line began with Henry Tudor, Earl of Richmond, the grandson of Sir Owen Tudor, a Welsh knight of distinction, who, after the battle of Bosworth Field, was proclaimed king with the title of Henry VII (q.v.), from him the crown descended to his son, Henry VIII, whose son, Edward VI (q.v.), succeeded, and after him his two sisters, Mary (q.v.) and Elizabeth (q.v.). See also GREAT BRITAIN — THE REFORMATION IN ENGLAND.

TUDOR, William, American author: b. Boston, 28 Jan. 1779; d. Rio Janeiro, Brazil, 9 March 1830. He was graduated from Harvard in 1796 and entered the counting-room of John Codman, in whose employ he visited Paris. He afterward made a tour to Italy and the Continent, and on his return engaged in founding the "Anthology Club." In 1815 the first number of the *North American Review* appeared under his editorship, and three-fourths of the first four volumes were written by him. In 1819 he published 'Letters on the Eastern States,' in 1821 'Miscellanies' and in 1823 'Life of James Otis.' In 1823 he was appointed American consul at Lima, and in 1828 made chargé-d'affaires at Rio Janeiro, where he wrote a work published anonymously under the title 'Gebel Teir' (1829). He was one of the founders of the Boston Athenæum, and to him the country is indebted for the first suggestion of Bunker Hill monument.

TUDOR ARCHITECTURE, late Perpendicular work in England. There are three phases of this style of architecture: (1) The Early Tudor, from the reign of Edward IV to Henry VII, inclusive. Of this style there are no perfect buildings and only few traces remaining. The Palace of Shene, built by Henry VII, has totally disappeared; but, according to the Survey of 1649, it abounded with bay windows of capricious design, with rectangular and semi-circular projections, and was adorned with many octagonal towers, surmounted with bulbous cupolas of the same plan, having their angles enriched with crockets. (2) Tudor, in vogue during the reign of Henry VIII. The plan of the larger mansions of this period was quadrangular, comprising an inner and base court, between which stood the gate house. On the side of the inner court facing the entrance were the great chamber, or room of assembly, the hall, the chapel, the gallery for amusements, on an upper story, running the whole length of the principal side of the quadrangle, and the summer and winter parlors. The materials were either brick or stone, sometimes both combined. Molded brickwork and terra-cotta were also employed for decorative purposes. Among the more striking peculiarities were the gate houses, the numerous turrets and ornamental chimneys, the large and beautiful bay and oriel windows, hammer beam roofs and paneled wainscoting round the apartments. (3) Late Tudor, or Elizabethan, as seen in many country houses.

TUESDAY, the third day of the week, so called from the Anglo-Saxon god of war, Tiu, or Tiw. See TYR.

TUFA, a name applied to the cellular deposits from mineral springs. These are either silicious or calcareous. The former are classified under silicious sinter, the latter are called calc tufa or calc sinter. Calc tufa is a cellular variety of calcite in which the mineral matter has been deposited from the waters of springs around nuclei of leaves, twigs, mosses, etc. Many older writers extended the term to include "tuff," a usage not sanctioned at present.

TUFF, a name properly applied only to finely divided particles ejected from volcanoes by explosive eruptions, and only so called after partial or complete compacting. The most notable illustration is the volcanic ash which buried Pompeii. The term is not to be confused with "tufa" (q.v.).

TUFTS, James Hayden, American educator: b. Monson, Mass., 9 July 1862. He was graduated at Amherst in 1884 and at Yale in 1889 and took his Ph.D. at Freiburg in 1892. He was instructor in mathematics in Amherst (1885–87), in philosophy at the University of Michigan (1889–91) and in 1900 became head of the department. He also served as dean of the Sanior College (1904 and 1907–08), University of Chicago. He is the author of various monographs on philosophical subjects and became editor of the *International Journal of Ethics* (1914).

TUFTS COLLEGE, located at Tufts College Station near Medford, Mass. It was chartered in 1852 and first opened to students

in 1854; though established by members of the Universalist Church, it is non-sectarian in its policy and control. A notable feature of the first curriculum of the college was the special attention given to history; the policy has always been most liberal, and the courses have been constantly increased in number and broadened in scope in response to the tendencies of the modern educational development. Civil engineering courses were begun as early as 1869; and courses in other engineering departments added later; the first professional school was the Divinity School established in 1882; the Medical School was added in 1893, and the Dental College in 1899. All departments were open to women in 1892. In 1910 Jackson College for Women was opened as a department of Tufts College. The college organization now includes the following departments: (1) the School of Liberal Arts; (2) the Engineering School; (3) Jackson College for Women; (4) the Graduate School; (5) the Crane Theological School; (6) the two-year Pre-Medical School; (7) the Medical School; (8) the Dental School. The degrees conferred are A.B. and B.S. in the School of Liberal Arts, Engineering and Mechanics, and A.M. for graduate work. The courses leading to the degree of A.B. are largely elective, requirements being by groups, instead of by special subjects, and each group except English and physical training including electives; the science and engineering courses are more specialized in character, and include only a few electives. Shop work is included in the engineering course. The Bromfield-Pearson School is designed to furnish instruction for those who are deficient in some of the studies required for entrance to the engineering courses, but fitted to pursue the college courses in certain subjects. The Crane Theological School offers a four years' course leading to the degree of S.T.B.; in 1902 an arrangement was made by which the A.B. course could be combined with the theological course in such a way that both degrees could be obtained in five years. The Medical School offers a four years' course leading to the degree of M.D.; the Dental School confers the degree of doctor of dental medicine at the satisfactory completion of a four years' course. These two schools are located at Boston, occupying a large well-equipped building completed in 1902. An additional building for the Medical School was completed in 1917.

There are 82 scholarships and four special scholarships provided in the collegiate department and 12 in the Crane Theological School. The government of the college is vested in a board of 30 trustees, 20 of whom are self-perpetuating; to give the alumni as a body a representation in the college administration, 10 of the trustees are elected by the alumni, two each year for terms of five years. Alumni members of the board of trustees have the same power as the self-perpetuating members of the board. On the college campus there are (1918) 21 buildings; these are Ballou Hall, the Barnum Museum (built and endowed by P. T. Barnum), the Goddard Chapel, the Goddard Gymnasium, the Eaton Library, Packard Hall (occupied by the Crane Theological School), the chemical building, the Bromfield-Pearson School (containing the engineering shops), Robinson Hall, Miner Hall (occupied by Jackson College for Women) and Paige Hall, four dormitories for men, East Hall, West Hall, Dean Hall and Curtis Hall, five for women, Metcalf Hall, Start House, Richardson House, Gamma House and Knight House, and the power house. The general library in 1918 contained 74,000 volumes; in addition there are several special libraries, including the Universalist Historical Society collection (in Packard Hall), 6,000 volumes; the library of natural history (in the Barnum Museum), 2,500 volumes; the Metcalf musical library (in the Goddard Gymnasium), 1,600 volumes. The Medical and Dental schools also have libraries in their building in Boston, and students in these schools have access to the Boston Public Library. The productive funds in 1918 amounted to $2,256,000; the students numbered 1,645; the faculty numbered 255.

TUG-OF-WAR, a sport in which a number of persons divide into two parties; a line is marked out on the ground, and the two parties, laying hold of either end of a stout rope, try to drag each other across the line.

TUGBOAT, a small steam-vessel, having very large engines of great horse power and very little storage capacity, used for towing large vessels in and out of harbors, and in rivers and canals. More than 1,000 of these are employed in New York Harbor alone and are classed by boatmen under various names. Tugs are also of great service in forcing a channel through the ice; in rescue work if there is a wreck or a ship on fire; in transporting car floats for the railroad companies and in towing great rafts of logs.

TUGENDBUND, too'gĕnt-boont (German for "league of virtue"), a union ostensibly for the promotion of educational and social reforms, which was organized in Prussia in 1808, the real purpose being to free North Germany from the intolerable yoke of Napoleon. The Prussian government was apprehensive that the Tugendbund might involve it in further difficulty with the French emperor, then virtually master of Germany, and suppressed the movement in 1809.

TUGUEGARAO, too-gā-gä-rä'ō, Philippines, pueblo, capital of the province of Cagayán, Luzon, within a few miles of the Grande de Cagayán River, 215 miles north of Manila. It is on the main highway to Manila and is the centre of a fertile agricultural region. It is well built, many of the houses being of stone; it has a large public square, a church, courthouse and town-hall. Pop. 16,820.

TUILERIES, twē'lë-rĭz (Fr. twēl-rē, named from the "tile-works," which originally occupied the site), previous to 1871 the royal and imperial palace at Paris, situated almost in the centre of the city on the north bank of the Seine. It was founded in 1564 by Catherine de Médici, wife of Henry II. Later monarchs extended it and altered the plans, until it became a large, complex structure, but with little architectural interest. It was stormed and sacked by the Paris mob in each of the revolutions, but was restored, and served as the residence of all the monarchs of the 19th century, including the two emperors. In 1871 it was set on fire by the Communists, and al-

most totally destroyed. Only the two eastern wings connected with the Louvre remain. The rest of the site has been converted into a public garden. See PARIS.

TUKE, tūk, **Daniel Hack,** English physician: b. York, 19 April 1827; d. London, 5 March 1895. He studied at Saint Bartholomew's Hospital College, London, and was graduated from the University of Heidelberg in 1853. He afterward made extensive tours on the Continent, visiting the principal asylums for the insane and recording his observations, a practice he continued throughout his life. Upon his return from his first tour abroad he became visiting physician to the York Retreat for the Insane, but was compelled to retire in 1859 because of failing health. In 1875 he removed to London and until his death was engaged as consulting physician in mental diseases. He was associate editor of *The Journal of Mental Science* in 1878–92, collaborated with J. C. Bucknill in writing 'A Manual of Pyschological Medicine' (1857), and also wrote 'Illustrations of the Influence of the Mind on the Body' (1872); 'Insanity in Ancient and Modern Life' (1878); 'History of the Insane in the British Isles' (1882); 'Dictionary of Psychological Medicine' (1892), etc.

TUKE, Henry Scott, English writer and religionist: b. York, 1756; d. there, 1814. He was a distinguished minister of the Society of Friends and wrote several works which are considered standard authorities in that denomination. Among them are 'The Faith of the People called Quakers in our Lord and Saviour Jesus Christ, set forth in Various Extracts from their Writings' (1801); 'The Principles of Religion as Professed by the Society of Christians usually called Quakers, Written for the Instruction of their Youth and for the Information of Strangers' (1805), and 'Biographical Notices of Members of the Society of Friends' (1813).

TUKE, William, English philanthropist: b. York, 24 March 1732; d. there, 6 Dec. 1822. He was devoted to mercantile pursuits, principally in the tea and coffee trade. Belonging to the Society of Friends, his attention was called, through the death of a fellow-believer confined in the York County Asylum, to the necessity of ameliorating the condition of the insane. With his son Henry, Lindley Murray and other Friends he secured funds for the opening of the York Retreat in 1796. In this institution began in England the modern humane methods of treatment, a reform that, unknown to Tuke, Pinel was carrying out contemporaneously in Paris. Inmates were no longer kept in chains; restraint and irksome discipline were removed; quiet surroundings with some industrial occupation were provided. After his death important legislation on the treatment of the insane was the direct result of his reforms.

TUKUARIKA, too'kwä-rē'kä. See SHOSHONEAN INDIANS.

TULA, too'lä, Mexico, a town in the state of Hidalgo, situated on the railroad, 40 miles west of Pechuca, at an elevation of 6,750 feet. It has a church and convent built by the early Spanish settlers, and in the neighborhood are extensive ruins supposed to be remains of the old Toltec capital. Cotton is manufactured. Pop. 5,000.

TULA, Russia, (1) capital of Tula, on the Upa, 120 miles by rail south of Moscow. It is an important manufacturing place, has churches, museum, arsenal and government offices, and an ancient Kreml. Its industrial works include a large gun factory, sugar refinery, dye-works, factories for bicycles, small arms, samovars, harmoniums, bells and mathematical instruments, besides manufactures of soap, candles, sealing wax, etc. Pop. 140,620.

(2) Tula, is a government of central Russia, whose area comprises 11,954 square miles. Its surface is mostly flat, and almost everywhere capable of cultivation. There are extensive forests, and the principal streams are the Oka, Upa and Don. Canals connect the region with the Baltic, Black and Caspian seas. Agriculture and stock raising are important. Iron is extensively manufactured. Pop. 2,016,000.

TULALIP. See SALISHAN INDIANS.

TULANE, tū'lān', **Paul,** American philanthropist: b. Princeton, N. J., 6 May 1801; d. there, 27 May 1887. He came of a distinguished family of French jurists, the probate judgeship of Tours having been in the Tulane family for 150 years. His father, Louis Tulane, came to America about 1795 and settled on a farm near Princeton, N. J., where his family lived for many years. Paul's early education was limited to a common school training, and he worked on the farm and, later, assisted in keeping a small grocery. About 1819 he went to New Orleans, settled there, and with the aid of a French cousin, then in America, opened a general merchandize store in 1822. By 1828 he had amassed a fortune of $170,000, a large amount at that time. He continued in a prosperous mercantile career until 1858, when he retired from active business, purchased a residence in Princeton and divided his time between it and New Orleans for many years, continually increasing his property both in the Crescent City and at the North until his death. His interest in education appears to have been first awakened during the trip with his cousin in 1819 on observing several young Creoles from New Orleans on their way to Transylvania University, in Kentucky. He seems then to have been struck with the fact of the lack of educational advantages for these young people at their home. This interest bore fruit in the fact that, entirely without solicitation, he formed in 1882 a group of friends into a body which incorporated itself as "The Board of Administrators of the Tulane Education Fund." To them he gave in trust a considerable property, without specific instructions except that the fund donated was "for the promotion and encouragement of intellectual, moral and industrial education among the white young people in the city of New Orleans, State of Louisiana." By contract with the State, securing thereby exemption from taxation on its property, the board thus formed took over the University of Louisiana, founded in 1832, the name of which was then changed to Tulane University of Louisiana (q.v.). His first gift for educational purposes in New Orleans consisted of his New Orleans real estate, valued at about $363,000. By subsequent gifts his endowment was raised to a total of $1,100,000.

TULANE UNIVERSITY OF LOUISIANA, located in New Orleans. This institution, under its present name, was created by Act No. 43 of the legislature of 1884. Its oldest department is the Medical College, which was organized as a private enterprise in 1834, and which was the first medical college in the Southwest. In 1845 the first Democratic Constitutional Convention that assembled in the State provided for the establishment of an institution to be known as the University of Louisiana, which should embrace as one of its departments the medical college already in existence, together with a department of law, a department of natural sciences and of letters. The State refused to bind itself to support the new university, but in the years following the legislature appropriated about $100,000 for the equipment of the medical department and for a building to house it. The plans of the convention for the other departments were not realized until 1847. The first meeting of the board of administrators took place 27 April 1847. On 4 May of the same year the board decided that law lectures should begin the following November. On 1 June 1847 a committee was appointed to report on the organization of a department of letters and natural sciences. The first president of the university, elected 21 July 1847, was Dr. Francis Lister Hawks of North Carolina. The academic department existed only as a high school until 1851, when the college proper was opened with 12 freshmen and two sophomores. The medical college was the most successful department down to 1861, when the Civil War closed the university. At the close of the conflict the law and medical colleges were reopened, but the reopening of the academic department was delayed. In November 1878 the academic department was revived under Dean Richard H. Jesse. Beginning in 1879, the State made an appropriation of $10,000 a year for its support, the first regular appropriation it had ever received. Private munificence, however, was now to take the place of State appropriations. In 1882 Paul Tulane, a former merchant of New Orleans, made a large donation for the higher education of "the white young persons" in the city of New Orleans. This donation was augmented until it amounted to more than a million dollars. The acceptance of this gift was followed by the absorption of the old University of Louisiana, which was effected by Act 43 of the general assembly of 1884, and which has been ratified by the present constitution (1898). As a *quasi*-State institution the university is exempted from all taxation on its property, and in recognition thereof it remits all claim to the appropriation of $10,000 and gives a free scholarship to every legislative and senatorial district in the State. To the presidency of Tulane University of Louisiana the board called a distinguished soldier and scholar, Col. Wm. Preston Johnston, who labored until his death in 1899 to enlarge the usefulness of the institution. He was succeeded in 1900 by Dr. Edwin A. Alderman, who, in turn, was succeeded in 1905 by Dr. E. B. Craighead, in 1912 by Dr. Robert Sharp and in 1918 by Dr. Albert B. Dinwiddie. In 1886 Mrs. Josephine Louise Newcomb donated $100,000 to the Tulane University of Louisiana, for the higher education of white girls and young women. This endowment, to which Mrs. Newcomb added more than $2,000,000 during her life and in her will, has enabled the administrators of the university to offer to women the advantages formerly given only to men. In 1891 Mrs. Ida G. Richardson presented the medical department with a splendid modern building, equipped with every needed appliance for instruction in medicine. In the year 1894 the undergraduate departments were moved from the old contracted quarters (on Dryades street, near Canal), to a splendid site on Saint Charles avenue, opposite to Audubon Park in the best residential section of the city, and in 1918 Newcomb College was removed to its new site, adjoining the Tulane campus. In 1900 Mrs. Caroline S. Tilton gave to the university the present beautiful library building and in 1906 made an additional donation for the erection of the annex to the library. In 1902 Mr. Alex. C. Hutchinson bequeathed the sum of $800,000 to the university for the benefit of the medical department. The Richardson Memorial, on Canal street, was transferred to the Hutchinson Fund, and the proceeds of this transfer used for the erection on the campus of the Richardson Memorial Building, the enlargement of the Chemistry Building, which was renamed the Richardson Memorial Chemistry Building, and the Richardson Memorial Dormitory for medical students. In 1906 the New Orleans Polyclinic was acquired by the university, and is now the Graduate School of Medicine and in 1909 the New Orleans College of Dentistry became the School of Dentistry. In 1910 Mr. F. W. Callender bequeathed the sum of $65,000 to the university, which sum was set apart as a foundation for the establishment of the F. W. Callender Laboratory of Psychology and Education. In 1910 Mr. Stanley O. Thomas bequeathed the sum of $60,000 for the erection of a building to be known as Stanley Thomas Hall. As presently constituted the university comprehends the following colleges and schools: College of Arts and Sciences, College of Technology, H. Sophie Newcomb Memorial College for Women, Faculty of Graduate Studies, College of Law, College of Medicine (including School of Medicine, Graduate School of Medicine, School of Dentistry and School of Pharmacy) and the College of Commerce and Business Administration.

TULARE, Cal., city in Tulare County, on the Southern Pacific and the Atchison, Topeka and Santa Fé railroads, about 45 miles southeast of Fresno. It has an important trade in fruits and cereals and dairy products. There is a public library. Pop. about 3,000.

TULÉ, too'lĕ, the Spanish-American name of a variety of the bulrushes, *Scirpus lacustris* and *S. tatora,* so common in the overflowed lands of the southwestern United States that those districts are called tulé lands. *S. lacustris* is a tall, large, smooth-stemmed rush with an umbel of flower spikelets, and with the leaves reduced to mere sheaths. It has a thick, fleshy, perennial rootstock, eaten by the aborigines, and which when sun-dried and powdered is said to keep well, and to be of good taste. Tulé seeds, also, are eaten; and the stems are woven into mats and baskets, and, like reeds, are used in great bunches to form the curious craft called balsas.

TULIP, a genus of bulbous herbs of the family *Liliaceæ*. The species, of which about 100 have been described and 40 introduced into cultivation, are natives of temperate Asia, and some have become naturalized in the Mediterranean region of Europe. They are characterized by tunicated bulbs, linear or broad radical leaves from the base of which rises the scape three inches to two feet or more tall and bearing at its summit usually a solitary bell-shaped flower, sometimes two, three or even four. These flowers are large, brilliant and showy, single or double, generally erect but sometimes nodding. Their colors are red, yellow, white and variegated in a great variety of tints and markings.

For more than three centuries the tulip has been popular in European gardens and prior to this period it was cultivated by the Turks for many centuries. In 1753 Linnæus grouped the garden tulips under the botanical name *Tulipa gesneriana*, which has since been erroneously cited as that of the original species. Another form (*T. suaveolens*) was named in 1797. It was well known in southern Europe prior to this date, but seems to have been an escape and was formerly distinguished from other tulips then cultivated by its earlier bloom, larger size, pubescent scape and fragrant flowers. Hence the conclusion that the earlier garden varieties are probably derived from the latter species and the later ones probably from the former.

Interest in the tulip began in Vienna in 1554, when Busbequis, an Ambassador to Turkey, procured seeds from a garden near Constantinople. From that time forward the popularity of the plant increased rapidly. In 1591 specimens of Clusius' varieties stimulated interest in the plant in Holland, where the production of new varieties increased rapidly until it became a craze in 1634. From that date until 1637 the wildest speculation prevailed. Not only were enormous prices paid for individual bulbs, 13,000 florins (about $5,200) for a bulb of the variety *Semper Augustus*, but ownership was divided into shares, and many of the schemes known to the stock and bond market were in vogue, often without the existence of any bulbs at all. The government had at last to interfere but this was not until many families had been impoverished or even ruined financially. Since that time the popularity of the plant declined, but later reached the normal basis upon which it now rests, with its headquarters in Holland and Belgium. During the closing decade of the 19th century experimenters in the State of Washington have produced superior tulip and other bulbs, and will probably supply the American market.

The garden tulips are divided into four principal groups: selfs, in which the flowers are of only one color; roses, in which the petals show varying shades of red, scarlet and pink; bizarres, in which the petals have yellow bases or centres and are bordered more or less widely with orange, red, etc.; and bybloemens, dark-colored flowers — purple, maroon, brown, black, etc. In these various classes about 2,000 varieties are listed by the European bulb growers, and they are further divided into singles and doubles, and except the selfs are segregated into feathered and flamed, according as the colors are intermingled in narrow or broad stripes.

One of the most remarkable phenomena about tulips grown from seed is that after the plants began to produce blossoms for one or several years they «break»; that is, the colors and markings of the flowers change radically. A single-flowered self may become a double-flowered bizarre or rose, perhaps even showing no traces of the original tint. Owing to the length of time required to produce flowering bulbs from seed — three to seven years — this method of propagation is rarely practised except by originators of new varieties and by growers who supply small bulbs to fanciers and others. Named varieties are all propagated asexually, generally by offset bulbs which are usually produced freely. These do not «break» unless the progeny is obtained prior to the «breaking» of the parent bulb.

Tulip will grow in almost any garden soil, but will thrive best in well-drained friable loam of moderate texture and richness. The bulbs should be planted in mid-autumn four inches below the surface. During the winter, in the North they may be mulched with litter, evergreen boughs, etc., to keep the frost in the soil and prevent alternate freezing and thawing. In spring when the weather has become somewhat settled the mulch should be removed and the surface smoothed with a rake. After blossoming the leaves should be allowed to turn yellow before the plants are dug, if they are to be dug, in order to allow them to elaborate food for the next season's bloom. If desired they may be left in the ground for two or three years. When taken up they should be cleaned, the offsets removed, dried in the shade and stored in a cool dry place until planting time. For house and greenhouse use, the bulbs may be planted in flats or pots as soon as received from the seedmen, kept in a dark place until the roots are well produced and the tops begin to show; then they may be taken to a temperate room and gradually inured to both light and heat. After they have produced their blossoms they are usually thrown away because a fresh supply can be obtained so cheaply that the care usually required to «bring them around» again is considered wasted. However, they are sometimes planted in odd corners of gardens where some specimens will usually recover from the effects of the forcing. Consult Bailey, 'Standard Cyclopedia of Horticulture' (New York 1916); Solms-Laubach, 'Weizen und Tulpe und deren Geschichte' (Leipzig 1899).

TULIP-TREE, one of the handsomest and largest deciduous trees (*Liriodendron tulipifera*) in America, attaining its greatest dimensions in the Middle States, in deep, moist, loamy soils. It is remarkable for its absolutely straight, massive trunk, sometimes tapering from a base, 20 to 25 feet in girth, to a height of 150 feet. The bark is regularly ridged, but is of fine texture and ashen-hued. That of saplings is very smooth, grayish-green and mottled with gray. A tree grown in the open is of a symmetrical, pyramidal or spindle-like outline, with many diverging and upward sweeping branches. The foliage is very glossy and bright green, the leaves peculiar in form,

being nearly square, and three-lobed, the lateral lobes rounded at the base, the central one having a broadly-triangular notch taken out of its apex. They turn to a clear yellow in autumn, and the leaves, trembling on long petioles, have caused this tree to be confounded with the poplars, in popular nomenclature. When very young, the blade is bent down against its stem and is covered by two membranous boat-shaped stipules, which unite about the bud and do not separate and fall away until the tender leaf is able to endure the weather.

The tulip-tree is one of the magnolia family, and in June is covered with handsome flowers, which have suggested the generic name, meaning "lily-tree"; but the vernacular term seems more apt, since the six petals have the flaring, cup shape of the tulip. They are solitary, terminating the branchlets, and are yellowish-green outside, lined with orange, with a suggestion of a green star at the base. A ring of stamens stands inside, surrounding the column of carpels. The fruits persisting long after the leaves have fallen, are like long samaras, hung by slender stalks, on the cone-shaped receptacle, and overlap it like inverted shingles. During the winter they are torn away and drift hither and thither.

The heartwood is classed among light woods, is easily worked, has a compact fine grain, and takes a high polish; when perfectly seasoned, it is durable and resists insects' attacks, but is likely to warp and shrink if not well dried. The color may be either white or yellow, and the wood is known as white or yellow poplar, the latter variety being the better. At one time used greatly for house-building, furniture, wooden utensils and many other purposes, on account of its lightness and strength, it is also valuable for carriage panels. Indians were said to have wrought it into long canoes, so regular and light were the trunks. An infusion of the bark when added to an equal quality of dogwood is reckoned as a remedy for intermittent fevers, when alone as a substitute for cinchona and as a gentle cathartic. Many fossil species have been found, representatives of the *Liriodendron* type, of which it alone survives.

TULL, Jethro, English agriculturist: b. Basildon, Berkshire, 1674; d. near Hungerford, Berkshire, 21 Feb. 1741. He was educated at Oxford, and was called to the bar in 1699. He appears to have had political ambitions, but ill health compelled their abandonment and after an extended tour of Europe he settled on his estate and devoted himself to agriculture. In 1809 he removed to his farm near Hungerford which he christened "Prosperous Farm" and continued his experiments. He introduced the system of planting in rows and pulverizing the soil between them, but made the serious mistake of considering the finely pulverized earth and moisture sufficient for the growth of the plants and dispensed with fertilizing the soil, a system which involved him in serious losses. He invented the drill-plow and published 'New Horse-Hoeing Husbandry' (1733), a work which was long an authority in England.

TULLAHOMA, Tenn., city in Coffee County, on the Nashville, Chattanooga and Saint Louis Railroad, about 69 miles southeast of Nashville. It contains the Chautauqua grounds, the Pythian Home, the Fitzgerald and Clarke Preparatory School, the State Vocational School for Girls, the Cumberland, Pylant and Hurricane Springs. Its manufactures include buggies, golf sticks, overalls and tobacco products. Pop. about 4,000.

TULLAHOMA, tŭl-ą-hō'ma, or **MIDDLE TENNESSEE, CAMPAIGN.** When General Bragg after the battle of Stone River or Murfreesboro (q.v.) fell back from Murfreesboro he designed to hold the line of Elk River, but was directed to hold that of Duck River, north of which he disposed his forces; his infantry front extending from Wartrace on the right to Shelbyville on the left, with cavalry on the right at McMinnville and on the left at Columbia and Spring Hill. Polk's corps, on the left, held Shelbyville, which was well fortified, and a strong detachment was thrown forward about 10 miles to Guy's Gap. The greater part of Hardee's corps held Hoovel's, Liberty and Bell Buckle gaps, and part of it was at Tullahoma, 36 miles south of Murfreesboro, which was fortified and held as a depot of supplies. Bragg's position was covered by a range of high, rough, rocky hills, the principal routes passing southward from Murfreesboro toward Tullahoma and the line of his communications with Chattanooga, being the Manchester road through Hoover's Gap, the Wartrace road through Liberty and Bell Buckle gaps and the Shelbyville road through Guy's Gap, all of which were strongly held. His cavalry, under Generals Wheeler and Forrest, was very active, attacking posts and detachments in Rosecrans' rear and on his flanks, breaking railroads and capturing wagon trains and in every manner harassing him, and to prevent which Rosecrans was but feebly prepared, having a much inferior cavalry force in point of numbers.

Early in January 1863, the troops of the Army of the Cumberland, under General Rosecrans, were organized into three army corps, designated the 14th, 20th and 21st, commanded respectively by Gens. Geo. H. Thomas, A. McD. McCook and T. L. Crittenden. There was a reserve corps, under Gen. Gordon Granger, and a cavalry corps, commanded by Gen. D. S. Stanley. There were in the early months of 1863 many reconnaissances, which brought on several severe engagements. and the cavalry was kept busy by Wheeler and Forrest. Rosecrans was pushing his preparations for an active campaign and keeping up a fruitless appeal to the authorities at Washington for an increase of his cavalry force. By the middle of June he had decided upon a campaign to drive Bragg from middle Tennessee and fully informed that he was strongly intrenched at Shelbyville and Tullahoma determined to render these intrenchments useless by turning Bragg's right and moving on the bridge across Elk River in his rear, thus compelling his retreat or to give battle on open ground. He says: "To accomplish this it was necessary to make Bragg believe we could advance on him by the Shelbyville route, and to keep up the impression, if possible, until we had reached Manchester with the main body of the army. . . . The plan was, therefore, to move General Granger's command to Triune, and thus create the impression of our intention to advance on them by the Shelbyville and

Triune pikes, while cavalry movements and an infantry advance toward Woodbury would seem to be feints designed by us to deceive Bragg and conceal our supposed real designs on their left, where the topography and the roads presented comparatively slight obstacles and afforded great facilities for moving in force." Rosecrans had about 50,000 infantry, 6,800 cavalry and 3,000 artillery; Bragg 30,000 infantry, 14,000 cavalry and 2,250 artillery. The campaign was opened by Rosecrans on 23 June, when Mitchell's cavalry division moved from Triune, and drove Wheeler's cavalry back upon the infantry with sharp skirmishing at Eagleville, Rover and Unionville. At the same time General Granger, with part of his own corps and Brannan's division of Thomas', moved from Triune to Salem, and the rest of the army was ordered to be in readiness to march next morning with a good supply of rations. On the next morning McCook started from Murfreesboro, on the Shelbyville road, and then moved to the left for Liberty Gap, which was seized before night by R. W. Johnson's division, after a sharp skirmish with a part of Cleburne's division. Thomas advanced on the Manchester pike; Wilder's brigade of mounted infantry in advance drove some Confederate cavalry through Hoover's Gap to its southern extremity when it was fiercely attacked by infantry and held on until Thomas came up with infantry, when the Confederates withdrew, leaving Thomas in full possession of the gap. Two divisions of Crittenden's corps moved to Bradyville, near Woodbury. On the other flank Granger and Brannan advanced from Salem to Christiana, and Stanley, with a division of cavalry, moved through Salem and joined Mitchell at the intersection of the Salem and Christiana roads. During the day Mitchell had had a sharp encounter with Wheeler's cavalry at Middleton. Stanley, having driven Wheeler's cavalry back to Guy's Gap, on the 25th, joined Granger at Christiana. On the left Crittenden advanced to Holly Springs; Brannan joined Thomas at Hoover's Gap, and Rousseau's division closed up on Reynolds', which was skirmishing in advance of the gap. During the afternoon three brigades of Stewart's Confederate division attacked two brigades of Johnson's and one of Davis' at Liberty Gap, to regain it, under the impression that Rosecrans was intending to march his main body through it. The attack was repulsed with a Union loss of 231 killed and wounded; and a Confederate loss of over 400. On the 26th Thomas pushed the Confederates back to within five miles of Manchester; Crittenden followed Thomas; McCook remained at Liberty Gap and Granger at Christiana. Thomas had gained so much ground toward Manchester that it was now practicable to concentrate the whole army there and force Bragg to abandon his position or give battle outside his works, and the concentration began on the 27th. Early in the morning Thomas seized Manchester, capturing a few prisoners, and at midnight had concentrated his entire corps at that place, 12 miles from Tullahoma. McCook withdrew from Liberty Gap, and marching through Hoover's Gap followed Thomas. The steady advance of Rosecrans' columns on Bragg's right convinced the latter that it was impossible to hold the long line to Shelbyville, so, early on the morning of the 27th, Polk was withdrawn from that place to Tullahoma, Wheeler, with the cavalry, being left to cover his rear. Stanley's cavalry and Granger's corps advanced from Christiana, drove Wheeler from Guy's Gap and pursued him inside the intrenchments four miles north of Shelbyville, where Wheeler made a stand with Martin's division to cover Polk's wagon train then on the road from Shelbyville to Tullahoma. Wheeler was driven from the intrenchments by Minty's cavalry brigade and pursued into Shelbyville. He crossed Duck River and was about to burn the bridge when he was informed that Forrest, who had been ordered from Franklin to Tullahoma, was approaching with two brigades to join him, upon which he hurriedly recrossed to the north side of the river, with Martin, 500 men and two guns, and had scarcely crossed when the Union cavalry came charging right down the main street and toward the guns. These had been loaded with canister and were discharged when the Union cavalry were only a few paces from their muzzles. But the charging cavalry rode over Wheeler and his 500 men, took the guns and covered the entrance to the bridge. Wheeler ordered a charge, cut through a part of the thin Union line, dashed down the steep river bank and swam the stream. Wheeler, Martin and some of the men escaped, about 50 were killed or drowned, many were made prisoners. Forrest had turned back when near Shelbyville and making a detour of eight miles crossed the river and marched to Tullahoma. It was dark when the action closed and the Union troops bivouacked at Shelbyville. As Bragg had now been forced from his first line on the right and from Shelbyville on the left, Rosecrans directed his attention to force him from Tullahoma back beyond the Tennessee. Thomas began the movement. Early on the morning of the 28th Colonel Wilder, with his brigade of mounted infantry, started from Manchester to burn Elk River bridge and break the railroad south of Decherd, in the rear of Tullahoma, and to support the movement Col. J. Beatty's brigade marched to Hillsboro. The Elk River bridge was found too strongly guarded to warrant an attack and Wilder marched for Decherd, which was reached at 8 P.M. Wilder burned the depot and water-tank and had destroyed about 300 yards of the railroad, when he withdrew upon the approach of Confederate infantry. Next day he broke up the Tracy City Railroad, and then dividing his force advanced toward Anderson and Tantallon, on the railroad to Chattanooga. Both places were held in such force that he made no attack and uniting his command at University he returned to Manchester on the 30th. When Wilder moved out on the 28th Thomas threw two divisions in the direction of Tullahoma and next day there was a general movement on the place and on the night of the 30th the advance was within two miles of it; the three corps of Thomas, McCook and Crittenden closed up, and Stanley's cavalry had come over from Shelbyville and bivouacked at Manchester. The concentration was effected with great difficulty. When the campaign opened the weather was fair and the roads good, but on the second day a heavy rain set in which continued during the entire movement and the roads became almost impassable for artillery and the trains, making the operations exceedingly slow. On the 29th

Bragg was reinforced by General Buckner, with 4,000 men, from Knoxville, and he proposed to give Rosecrans battle at Tullahoma, but when his communications with Chattanooga were so seriously threatened, he concluded to withdraw, and on the night of 30 June abandoned Tullahoma and fell back beyond Elk River. Thomas advanced on the morning of 1 July and occupied Tullahoma, and Rosecrans ordered an immediate pursuit, but Bragg held the crossings of Elk River, the pursuit was abandoned and Bragg continued his retreat over the Cumberland Mountains and across the Tennessee River to Chattanooga, leaving middle Tennessee again in Union possession. The nine days' campaign was one of the most brilliant of the war. Rosecrans' loss was 84 killed, 473 wounded and 13 missing. Bragg's loss in killed and wounded is not known. Rosecrans reports that he left in his hands 1,634 prisoners and 11 guns. Consult 'Official Records' (Vol. XXIII); Van Horne, 'History of the Army of the Cumberland' (Vol. I); The Century Company's 'Battles and Leaders of the Civil War' (Vol. III).

E. A. CARMAN.

TULLOCH, tŭl'ŏk, **John,** Scottish educator and ecclesiastical writer: b. near Tibbermuir, Perthshire, 1 June 1823; d. Torquay, England, 13 Feb. 1886. After study at Saint Andrews he became assistant minister at Dundee (1844), and principal and professor of theology at Saint Mary's College, Saint Andrews, in 1854. He edited *Fraser* in 1879, and was dean of the Chapel Royal, London, in 1882. A broad theologian, and the founder of the Scottish Liberal Church party, he nevertheless championed orthodoxy, and opposed disestablishment. In 1872 he lectured in the United States. He published 'Leaders of the Reformation' (1859); 'English Puritanism and its Leaders' (1861); 'Beginning Life' (1862); 'The Christ of the Gospels and the Christ of Modern Criticism'; 'Lectures on Renan's Life of Jesus' (1864); 'Theology and Greek Philosophy in England in the 17th Century' (1872); 'Pascal' (1878); 'Movements in Religious Thought in Britain during the 19th Century' (1885); and several volumes of sermons. He gained the second Burnett prize of £600 for an essay 'On the Being and Attributes of God,' which was published under the title 'Theism: The Witness of Reason and Nature to an All-Wise and Beneficent Creator' (1855).

TULLUS HOSTILIUS, tŭl'ŭs hŏs-tĭl'ĭ-ŭs, king of Rome in succession to Numa Pompilius (672 B.C). He was a warlike monarch, in whose reign took place the combat of the Horatii and Curiatii. (See HORATII). He subdued and utterly destroyed Alba by treachery. He likewise conquered the Fidenates and Sabines. His death, after a reign of 33 years, is ascribed by some to lightning, by others to assassination by Ancus Martius, his successor.

TULSA, Okla., the county-seat of Tulsa County, situated on the Arkansas River in the heart of the Mid-Continent Field, of which it is the financial, commercial and transportation centre. Tulsa is known as "The Wonder City" and the oil capital of the world, there being more than 500 operating oil and refining companies located in the city. A survey of Tulsa shows that it has a greatly diversified industrial activity, giving employment to 14,640 men, with an annual pay-roll in excess of $20,000,000. Tulsa has eight large refineries, a number of iron works, boiler works, stove works, tool works, machine shops, glass factory, smelter and approximately 150 small and large industrial plants, and a number of wholesale and jobbing houses, several coal companies, 13 public service corporations. The city is served by the Atchison, Topeka and Santa Fé, the Midland Valley, the Missouri, Kansas and Texas and the Frisco railroads, with three local systems of street railways. Tulsa has a practically unlimited supply of natural gas, of cheap fuel oil and coal, which is being mined within a few miles of the city limits. The bank clearings in Tulsa for 1918 were $489,983,156, the clearings being the largest of any city in the State. Tulsa had, under the call of the comptroller of the currency on 4 March 1919, on deposit in the 10 local banks $51,427,337 and the bank clearings for the city average $1,500,000 per day. The building permits for Tulsa since 1 Jan. 1917 are $14,997,178, the permits for April 1919 being in excess of $650,000 and representing permits issued for 148 homes. Tulsa is a city of splendid homes costing from $3,000 to $150,000; of good substantial business houses and has a number of eight-story, 10-story, one 11-story and one 17-story office building. The elevation of Tulsa is 750 feet and the average rainfall 36 inches with a mean temperature of 60°. The city has a fine convention hall, seating 4,000 people; a new Y. M. C. A. building, costing a quarter of a million dollars; a Y. W. C. A. building, costing approximately the same amount; a splendid public library; a modern county courthouse; a fine municipal building; an imposing government post-office building, with numerous club buildings. There are 30 churches; 475 schoolrooms built largely on the unit system, with a high school costing $550,000 and $1,000,000 was recently voted for the extension of the educational facilities. The county is now spending $2,000,000 for permanent hard surfaced roadways under a recent bond issue. Stock-raising, dairying and diversified farming are successfully conducted in Tulsa County and the truck grower has wonderful opportunities presented along the valley lands of the Arkansas River. Tulsa is known as the millionaire city, the local Chamber of Commerce having one committee of 50 men with every member of it worth more than $1,000,000 and some of them worth more than $10,000,000, these fortunes having been made from the oil industry in the Mid-Continent Field. The city is the headquarters for oil field supplies for Kansas, Texas and Oklahoma and is the financial clearing point for the great oil transactions of the Mid-Continent Field. All of the fraternal organizations which are popular in the Southwest are represented; there are six noon day lunch clubs of civic societies; beautiful parks, paved boulevards and paved streets, stately homes and modern business establishments. In the late war the city gave more than 10,000 men to the war and war work through three volunteer military units and through the draft and recruiting offices. Tulsa subscribed for the Liberty Loans as follows: First, $5,685,000;

SECTION IN THE BUSINESS DISTRICT OF TULSA, OKLA.

second, $6,450,000; third, $4,623,400; fourth, $8,240,560; fifth, $5,300,000. There are seven newspapers and periodicals published in Tulsa. The Tulsa *World* and Tulsa *Times* are the morning papers; the Tulsa *Democrat* and the Tulsa *World* are the afternoon papers. The Tulsa *Spirit*, the official organ of the Chamber of Commerce and Allied Interests of Tulsa, is a monthly publication with a national circulation. The city is under the commission form of government, having a mayor and four commissioners. The police and fire departments are efficient and well organized, being provided with every modern equipment for the protection of life and property. From a population of 1,390 in 1900, the city had grown to 78,755 in 1918.

TUMACACORI MISSION NATIONAL MONUMENT. In southern Arizona, 45 miles south of Tucson on the Nogales branch of the Southern Pacific Railroad. The full name is Saint Joseph of Tumacacori. It was founded within a year or two of 1687 by Fathers Francisco Kino and J. M. Salvatieraz, Jesuit missionaries to the Indians. The building which is in the form of a Greek cross with basilica was built of adobe bricks, plastered with cement and coped with burnt brick. The roof was flat and covered with tiles. The basilica remains. It was near the old presidio of Tubac in a rich valley and was at one time an important centre. This mission and 10 acres surrounding it were donated to the government in 1918 and made into a national monument.

TUMAL, the name given by the Avars to the Kasikumuks (q.v.).

TUMBREL. See DUCKING-STOOL.

TUMERIC PAPER. See TEST-PAPERS.

TUMOR (Lat. *tumor,* from *tumeo,* to swell). Terms frequently used in the same sense are new growth, neoplasm, malignant disease. A neoplasm or tumor in the narrower sense is a new formation of tissue, apparently arising and developing independently, atypical in structure, inserted uselessly into the body, possessing no function of service to the organism and showing no typical termination to its growth. (Ziegler).

The frequency with which tumors occur, the resistlessness with which many of them carry their victims on to a painful death and our ignorance in regard to their true nature combine to render their study one of the most interesting and important departments of pathology. In spite of the enormous amount of research which has been devoted to this field we must admit that though the *histogenesis* or structure of tumors is now fairly well understood, their *pathogenesis* or underlying principle of causation is still shrouded in mystery. We have learned that the ultimate cells and tissues which make up the substance of these new growths are the same in type as those normally occurring in the body, and that each structural element of the tumor is derived from a pre-existing element of similar nature, but what was the force or stimulus which enabled these cells to break the laws of inter-relationship which ensure the normal development and function of each part of the body is still unknown. See CELL; DEVELOPMENT HYPOTHESIS; HEREDITY; HISTOLOGY.

It is this tendency to assume an independence of existence and to flourish in opposition to the physiological restraints to which normal cells are subject in their growth and function that characterizes tumors and forms the chief point of difference between them and certain inflammatory and other tissue proliferations. In short, a tumor is an overgrowth of tissues beginning locally, but frequently, by various methods of extension, invading near or remote regions, which is never of use to the body and frequently is directly hostile to it. The lower animals, particularly mammals, are subject to the same aberrancies of cell growth, and tumors comparable to those occurring in man are observed in all the vertebrates. Plants also exhibit analogous formations. See VETERINARY MEDICINE.

General Characters of Tumors.—As has been indicated, the integral structural units of tumors may always be traced back to normal types, and each class of new growths takes origin from corresponding normal tissues. Thus epithelial tumors spring from epithelial tissues, connective tumors from connective tissues, etc. Viewed as a whole a tumor is a true parasite, since it leads an independent existence, deriving nourishment from its host without in any way contributing to the latter's welfare. The processes of growth, nutrition and cellular reproduction go on in tumors much as in normal tissues and they are provided with a connective tissue framework, blood and lymphatic vessels and nerves to provide for their vital needs. Interference with nutrition or other causes lead to degenerative changes and necrosis, and inflammation, cicatrization, ulceration, etc., take place in their customary manner. A tumor may continue to increase indefinitely in size, or it may in some instances become quiescent in growth and remain without change for longer or shorter periods of time. The growth of the tumor goes on independently of the rest of the body and often is at its expense; thus a lipoma or fatty tumor may continue to extend in size even after the body's reserve of fat has become exhausted. Growth is effected by three different means: (1) By central or expansile growth due to increase of elements within the tumor, so that the surrounding tissues are pushed aside. This has been likened to the increase in size produced by inflating a rubber balloon. (2) By infiltration, that is, the outlying portions of the tumor push their way into the surrounding tissues as do the roots of a growing plant. (3) By metastasis. The importance of this method of growth lies in the fact that it represents the means of dissemination by which remote parts of the body may be invaded. The blood or lymph vessels are broken into and bits of tumor tissue travel to a greater or less distance till they lodge in some tissue or organ and form initial foci of secondary or daughter tumors. In carcinoma the adjoining lymphatic glands through their close connection with the lymph current are usually the first structures to be secondarily invaded. From a clinical standpoint it is usual to divide tumors into two great classes: (1) Malignant; (2) non-malignant. There is also a small group of neoplasms which stand between these two and are sometimes malignant and sometimes behave like benign growths. The malignant tumors (or what in popular parlance are called "cancers") embrace the carcinomata and sarcomata and possess certain invariable character-

istics: (1) Their growth is by infiltration and destruction of the surrounding tissues; (2) they form secondary growths by metastasis; (3) they are difficult to extirpate surgically and tend to recur locally; (4) they induce a general disturbance of health known as cachexia. By this is meant a condition of defective nutrition due wholly or in part to the demands on the body made by the growth of the tumor, to its interference with digestion or food absorption if situated in certain parts, as the œsophagus or stomach, to the loss of albuminous material through the constant discharge from ulcerating areas, to the absorption of deleterious substances arising from putrefactive changes in the tumor, to hemorrhage, to the pain and resulting loss of sleep, anxiety, etc. It is possible that the tumor itself produces a poison which contributes in producing cachexia, but portions of human carcinomata introduced into the tissues of experiment animals if free from bacterial contamination do not appear to exert any toxic effects.

The benign tumors, on the other hand, are distinguished by usually being encapsulated so that they can be easily extirpated through the absence of any tendency to form metastases. They are dangerous to life only through compression of important organs, but it must be remembered that their position may in this way give rise to most serious conditions. Many varieties are also extremely liable to become the seat of malignant degeneration.

Theories of Causation and the Occurrence of Tumors.— Comparatively little is yet known in regard to the actual causes of tumor formation. Many highly ingenious theories have been elaborated, but plausible as they may seem they are mere speculations and none of them can be said to be satisfactory from every point of view. Cohnheim in 1882 promulgated a doctrine which has many adherents and affords a rational explanation at least for congenital tumors and for many benign new growths. Briefly stated, his view is that during the development of the embryo (see EMBRYOLOGY) small clusters of cells become displaced from their normal surroundings and form little islets of tissue different in nature from their environment. These cells remain alive, but lie dormant until some stimulus stirs them into activity and they then form the nucleus for tumor formation. Having once started to proliferate they exhibit the intense vital energy of embryonal tissue and develop untrammeled by the restraints imposed upon normal cell growth. This theory has much in its favor, such as the tendency of many tumors to develop in regions which correspond to embryonal foldings, and to assume embryonal types of structure, but it is impossible to demonstrate any such displaced aggregations of cells, and clinical observations in many cases are strongly against it. A somewhat broader and more general view is taken by Ribbert, who believes that through some means, perhaps as the result of injuries or inflammation, numbers of healthy cells become cut off by bands of connective tissue and are thus isolated from the physiological restraints which ordinarily keep the cellular capacities within normal bounds. As a result of this liberty, excessive growth and perverted activity, in other words, tumor formation, occur. Hansemann denies that mere segregation of cell groups can have this result and accounts for the great intensification of vitality necessary by assuming a change in the individual cells, termed anaplasia, consisting in a loss of differentiation and increased capacity for independent existence. According to this writer two factors, anaplasia and a proliferative stimulus, are necessary for tumor formation. It will be seen that these theories leave much to be desired, but it is probable that the truth lies in this direction of cytological research and that as we gain a deeper insight into the physiology of the normal cell our understanding of these complex perversions of growth will be correspondingly increased.

Much has been written of late on the parasitic origin of tumors, particularly of carcinoma, and bacteria, yeasts and protozoa have all been described and figured in great detail as causative agents. None of these so-called cancer parasites has, however, been able to withstand the crucial tests of cultivation and of reproducing the tumors on inoculation into animals, and it has also been impossible so far to infect animals of one species with tumor tissue derived from another. Belief in the infectious nature of carcinoma is shared by very few observers at present, and it is probable that the instances in which carcinoma has occurred in people intimately associated, as husband and wife, are either due to coincidence or to direct transplantation of cancer cells. So-called "cancer houses" and cancer districts are described, but such observations are too fragmentary and unreliable to be taken as the basis for generalizations.

Climatic, racial and geographical features have been drawn into the discussion by some authors, as well as matters of diet; for example, habitual over-indulgence in meat. In connection with this latter point it is an interesting fact that carcinomata are said to be much less frequent in herbivorous than in carnivorous animals. On the other hand carcinoma is not uncommon among religious sects in the East that are strict vegetarians.

Injuries, both acute, such as blows and falls, and in the form of long-standing irritation, undoubtedly have some connection with tumor formation. Acute trauma is most often associated with tumors of the connective tissue group, and chronic trauma with carcinomata. Typical examples are found in the cases in which sarcoma follows bone injuries, and carcinoma of the lower lip is apparently produced by the constant irritation of pipe smoking or of a roughened tooth. Certain occupations which involve chronic irritation of the skin through chemicals, such as tar or paraffin products, also seem to predispose toward tumor formation. Too much importance must not be attached to this factor, however, for it has never been possible to produce tumors in animals experimentally in this way, and in the cases in which new growths have followed trauma there was probably some already existing predisposition.

Age.— The liability to different sorts of tumors varies very considerably with different periods of life. In childhood and in early adult life carcinomata are rarely seen and of the malignant tumors sarcoma predominates, while the reverse is the case after the age of 30. To this rule there are many exceptions, however. When young people do acquire carcinoma the

disease is always of extremely virulent type, whereas in the very aged its development is slower and in particular the formation of metasases is much less extensive.

Sex.— Carcinoma is much more frequent in women than in men and the organs of predilection also differ in the sexes. In men the tongue, lips and stomach are oftenest attacked, while in women the disease is most commonly seen in the breast or uterus.

Heredity.— The tendency of modern pathologists is to ascribe less and less importance to heredity as a cause of tumor formation. Statistics are particularly misleading in this regard and while it is undoubtedly true that in a considerable proportion of cancer cases more or less remote members of the same family have been similarly affected, a like inquiry into the antecedents of healthy persons would show approximately similar results. A celebrated case is that of Napoleon I — who, as well as his father and two sisters, died of carcinoma of the stomach. Carcinoma is a common disease and, therefore, appears frequently in the same family; sarcoma is rare and so has less appearance of hereditary transmission.

Increase of Malignant Disease.— The statistics of recent years show that throughout the world, but particularly in England, there seems to be a marked increase in the occurrence of carcinoma. Roswell Park says that if the ratio of increase in the number of cancer deaths in New York State continues unchanged for the next 10 years the mortality from this cause will be greater than that of pulmonary tuberculosis, smallpox and typhoid fever combined. These figures cannot be accepted without some reservation, however, for undoubtedly the diagnosis is now made in cases that were formerly unclassified, autopsies are more frequent and the causes of death are more definitely indicated in death certificates. Also through municipal sanitation, improved methods of medical treatment, more widespread dissemination of the laws of hygiene, etc., a greater number of people now live to reach the age when carcinoma is frequent. The increase seems to affect principally those of the upper ranks, in contradistinction to tuberculosis which spreads most actively among the proletariat.

In conclusion, it may be said that probably no one cause underlies the formation of all types of tumors, but that possibly widely differing factors may be concerned in the production of the different varieties.

Classification of Tumors.—Until our knowledge of the causes of tumors becomes more exact, a satisfactory classification is impossible. The so-called histogenetic classification based on embryological data is open to many objections, as well as various other systems proposed. The following table is taken from Delafield and Prudden's 'Handbook of Pathological Anatomy and Histology.'

Connective-Tissue Type.

Normal Tissue.	*Tumors.*
Fibrillar connective tissue.	Fibroma.
Mucous tissue.	Myxoma.
Embryonal connective tissue.	Sarcoma.
Endothelial cells.	Endothelioma.
Fat tissue.	Lipoma.
Cartilage.	Chondroma.
Bone.	Osteoma.
Neuralgia.	Glioma.

Muscle-Tissue Type — Myomata.

Normal Tissue.	*Tumors.*
Smooth muscle tissue.	Leiomyoma.
Striated muscle tissue.	Rhabdomyoma.

Nerve-Tissue Type — Neuromata.

Vascular-Tissue Type — Angiomata.

Normal Tissue.	*Tumors.*
Blood-vessels.	Angioma.
Lymph-vessels.	Lymphangioma.

Epithelial-Tissue Type.

Normal Tissue.	*Tumors.*
Glands.	Adenoma.
Various forms of epithelial cells, and associated tissues.	Carcinoma.

To these may be added the following two groups:

Teratomata and Cystomata.

It will be observed that the designation for each form is derived by adding the suffix *-oma* to the technical name of the corresponding tissue type, and for mixed tumors compound names are formed, as adeno-carcinoma, myxo-sarcoma, etc.

Different Varieties of Tumors.— *Malignant Tumors — Sarcoma.*— Sarcomata are tumors of the connective tissue group, composed of cells, embryonal in type, which are disproportionally numerous in comparison to the basement substance, so that the tumor as a whole is usually soft and pulpy in contradistinction to the stony hardness of carcinomata. They are characterized by extreme vascularity, the new formed vessels often being mere channels between the tumor cells, and the tendency to form metastases by means of the blood current rather than the lymphatics. Their cells may be of many varieties and the following chief types are recognized: (1) Large and small spindle celled; (2) large and small round celled; (3) giant celled; (4) melano sarcomata, which contain pigment, frequently arise from pigmented moles and are extremely malignant. Mixed tumors, such as osteo-sarcomata, angio-sarcomata, etc., frequently occur. Sarcomata may arise from bone, the brain and spinal cord, the breast, the kidney, uterus and lymph glands. They grow rapidly, owing to their vascular structure, are prone to necrotic changes and if situated on the surface of the body break down and ulcerate. Sarcoma is not common, is a disease of early life, rarely appearing after the age of 40, and frequently is a sequel of injury or inflammation. In many respects sarcoma behaves like a growth due to some parasitic infection.

Carcinoma.— Carcinomata, or cancer in the true sense, are tumors composed of a more or less dense connective tissue framework, holding in its meshes epithelial cells. These exhibit much diversity of type and arrangement, so that several classes are recognized. (1) Epithelioma. This is the form which commonly occurs on the skin, at the muco-cutaneous junctions, such as the lips, about the nose and eye, and on the mucous membranes covered with squamous epithelium, as the mouth, œsophagus and cervix of the uterus. On the face a slowly growing form known as Jacob's or rodent ulcers is sometimes seen which may last for years and is rarely fatal. On the skin or lip epithelioma begins as a warty protuberance which soon ulcer-

ates and gradually extends in size until a sore with hard irregular base and edges, and foul bloody discharge, is formed. (2) Cylindrical celled carcinomata. These occur in the stomach, intestines and uterus. (3) Carcinoma simplex. This displays great irregularity in the shape of its cells and is the commonest form attacking the internal organs. If the connective tissue is in excess, the dense, hard *scirrhus* carcinoma results; whereas if the cellular elements preponderate, the tumor is termed a *medullary* cancer or *carcinoma molle.*

About 80 per cent of the tumors of the female breast are carcinomata. The disease is rare before the age of 35, is most common between 45 and 55 and in women who have borne children. The negro race is much less susceptible. It begins as a hard nodular mass not painful to pressure, which soon becomes firmly fixed to the tissues and causes retraction of the nipple. The axillary lymph-glands are invaded early and can usually be felt as small hard nodules. In neglected cases the skin over the tumor ulcerates and there is a foul discharge. The arm becomes swollen and useless, and pain of neuralgic nature is usually present. The bones, liver, pleura and brain are often attacked secondarily.

Carcinoma is usually disseminated by the lymph stream and promptly invades the lymphatic glands. According to Birch-Hirschfeld the following are in order of frequency the organs most often primarily attacked: Uterus, external skin, female breast, stomach, rectum, œsophagus, ovary, testicle, external genitals, prostate and bladder, pancreas, kidney, intestine, bile ducts, liver, bronchi. It is a disease of mature life and is not often seen before the age of 30.

Intermediate Tumors.— *Adenoma.*— Adenomata correspond in general structure to normal glands, but either do not secrete or are unable to discharge the secretion through the gland ducts. They grow slowly, but may reach a large size, particularly if distended by accumulated secretion. In this case they are termed cyst-adenomata, and the oftentimes huge ovarian cysts belong to this class. Many goitres (q.v.) are adenomatous tumors. Adenomata are in themselves benign, but are prone to take on carcinomatous tendencies and then become very malignant. They occur in the breast, the ovary, the thyroid gland, the kidney, salivary glands, stomach, intestines and uterus.

Endothelioma.— This tumor springs from the cells lining the blood vessels and lymph spaces and has much in common with both the carcinomata and sarcomata. Endotheliomata differ greatly in their virulence, but at times behave much as do sarcomata. They occur in the membranes of the brain, the pleura and peritoneum, the salivary and lymph glands. Growths of the parotid gland are frequently of this type.

Benign Tumors.— *Fibroma.*—This is a growth composed of bundles of fibrillar connective tissue. Two main types, the hard and the soft, occur. Fibromata frequently appear in young adults and may arise in any part of the body containing connective tissue. They are often seen in the skin, mucous membranes, the breast, in fibrous membranes, nerves and the gums, and are often associated with other forms of tissues in complex tumors. They are usually well encapsulated and may be single or multiple. Ordinary warts and moles and some nasal polypi are fibromata. One form not infrequent in women arises in the subcutaneous tissue, gives rise to severe attacks of pain and is called painful subcutaneous tubercle. Keloid is a form occurring in scars, which is most common in negroes and is very hard to eradicate.

Myxoma.— This tumor is made up of tissue embryonic in type and called mucous tissue. Myxomata are soft and elastic, grow slowly and are usually considered benign, though they have a tendency to recur and sometimes undergo sarcomatous change. They frequently occur as polypi (see POLYPUS) in the nose, where they give rise to chronic catarrh, and are also found in glands such as the parotid and breast, the subcutaneous and submucous tissues and the sheath of nerves. Myxomatous tissue is often found in mixed tumors.

Lipoma.— Fatty tumors are among the commoner growths and are composed of lobules of fat held in a stroma of connective tissue. They are most often seen in middle life, and the skin of the back or shoulders is a favorite site. They may be multiple and sometimes occur as diffuse fatty enlargements about the neck. The yellowish patches often seen about the eyelids in old persons are a form of lipoma called *Xanthoma.*

Osteoma.— Osteomata are composed of bone and usually originate in bone, periosteum or cartilage, though they may spring from other types of connective tissue. They grow slowly, are benign and are often multiple. A special form known as odontoma or dentigerous cyst develops from the germ of the permanent teeth.

Chondroma.— This is most often met with in the young and is composed of hyaline and fibrocartilage. Chondromata may form from the long bones, the pelvis, cartilage or in glands like the parotid and testicle. In the latter situations they are especially apt to become sarcomatous. Chondroma is frequently preceded by rickets in infancy. The so-called "joint-mice" or floating cartilages in joints are often pedunculated or broken off chondromata.

Glioma.— Gliomata are tumors developing from the neuralgia or supporting tissue of the central nervous system. They are found in the brain, spinal cord and cranial nerves. Some forms, particularly those occurring in the retina during childhood, are closely allied to the sarcomata, and owing to its situation glioma is always a source of danger.

Myoma.— Two varieties of myomata are recognized: (1) Leiomyoma, composed of unstriped muscle cells and more or less fibrous tissue; (2) rhabdomyoma, which is rare, and contains striped muscle cells and spindle cells. Growths of the first class are found in the œsophagus, stomach and intestine, the skin, bladder and ovary. They are commonest, however, in the uterus and its male analogue, the prostate gland. In the former situation they form the so-called uterine fibroids which often attain large size and may menace health through hemorrhage or pressure on adjoining structures. The prostatic enlargement of old age is due to leiomyoma of the gland. Myomata are tumors of later life.

Neuroma.— Tumors composed of nerve tissue or true neuromata are rare, arise in middle

life and are apt to be accompanied by severe pain or paralysis. False neuromata are tumors developing in the connective tissue sheaths of the nerves and may be fibromata, myxomata, etc. Traumatic neuromata are frequently the cause of the painful stump following amputations.

Angioma.—Angiomata are of two sorts: (1) Hæmangioma, consisting of dilated blood-vessels, and (2) lymphangioma, composed of dilated lymph-vessels. The first type is subdivided into (*a*) capillary hæmangiomata and (*b*) cavernous angiomata. Capillary angiomata or nevi form the so-called mother's marks, port wine stains or strawberry marks with which infants sometimes come into the world. These are patches of distended cutaneous capillaries or venules, and if small can be obliterated by electrolysis. Larger ones are treated by excision. Cavernous angiomata are made up of large vessels and if on the surface of the body may form swellings of considerable size. Lymphangiomata are usually congenital, but may be acquired and vary in size as do the hæmangiomata. With both classes of angioma there is danger of rupture and serious hemorrhage or escape of lymph.

Cystomata.— These are benign tumors filled with fluid the result of the activity of the cells lining the cyst wall, which is the real new growth. Many forms of cystomata belong to the adenomata; others occurring about the neck are the result of faulty closure of embryonic openings and are called branchio-genetic cysts. Cysts due merely to accumulation of secretion through stoppage of the duct of a gland, as the sebaceous cysts of the skin ("wens"), or resulting from parasitic infection as the hydatid echinococcus cysts (see HYDATID), are not grouped with true tumors.

Teratomata.— These are tissue formations of embryonic origin which frequently exhibit great complexity of composition and contain such diverse structures as bone, teeth, skin, hair, cartilage, muscle, glands, etc. Cysts of this sort are called dermoids and are especially common in the ovary and regions where folds of the developing embryo come in contact, as at the orbital angles, the neck and the base of the spine. Theoretically, teratomata are to be classed with the malformations rather than with the tumors. See TERATOLOGY.

The Diagnosis of Tumors.—In dealing with conditions likely to lead to results of such gravity as are involved in tumor formation, prompt recognition of the nature of the case is of the utmost importance. If taken at a sufficiently early stage both carcinoma and sarcoma can be cured by operation and impending danger from benign growths be recognized and averted. Swellings and ulcerations about the face and especially the lips and tongue which do not promptly disappear are, in older people, most suspicious. The formation of hard masses in the female breast should also be called to the attention of the physician as soon as noticed, and excessive menstrual flow or hemorrhage between the periods in younger women suggest the possible existence of uterine fibro-myomata. A bloody or malodorous discharge subsequent to the menopause is very likely to be due to carcinoma of the uterus. Dyspepsia in older people together with loss of weight point toward malignant disease of the stomach, and indefinite abdominal pain, emaciation, obstinate constipation or alternating diarrhœa and constipation, especially if there be blood in the stools, are strongly suggestive of a new growth of the intestine. It cannot be too strongly emphasized that delay is fraught with the greatest danger and may make cure impossible or add immeasurably to the difficulties of the operation. In doubtful cases where tumors are accessible it is the custom of surgeons to excise small bits of tissue and submit them to microscopic examination to determine their nature. In obscure abdominal disorders an exploratory laparotomy may be the only means of establishing the diagnosis. The procedure itself is as free from danger as any surgical manipulation requiring a general anæsthetic can be, and if malignant disease is present it may be possible to eradicate it and save the patient from the miserable death which is otherwise inevitable.

The Treatment of Tumors.— In general it may be said that for most tumors the proper treatment lies in their removal when feasible at the earliest possible moment. Modern surgery has made possible operations which formerly were unheard of and the chances of the patient afflicted with malignant disease are constantly improving. The older surgeons operated to prolong life or to make existence more bearable till death came as a relief: the surgeon of today operates to cure. Large portions of the stomach are frequently excised for carcinoma, and many cures are reported. Intestinal resection makes the extirpation of new growths in this region possible, while the technique of uterine operations has been developed to such a degree that fibromyomata can be removed with comparatively little risk, and even carcinoma in this situation has lost some of its terrors. Malignant tumors of the breast are permanently cured in from 40 to 50 per cent of the cases, the success being due to the thoroughness with which modern operators remove the tissues under the breast and the enlarged glands in the axilla, and statistics are showing constant improvement in the operative results in all forms of malignant disease. See SURGERY.

Various other plans of treatment are employed to some extent. Inoperable sarcomata have been greatly benefited by injections of bacterial toxins, and in the use of various forms of light-rays from the violet end of the spectrum, the X-rays and in the emanations from radio-active substances we have promising adjuncts to surgery. See PHOTOTHERAPY; RADIUM THERAPY.

Caustics are rarely successful in the treatment of malignant tumors and their application is always painful and leaves disfiguring scars. Charlatans of various types diagnose all sorts of conditions as cancers and proceed to cure them with great *éclat;* when actual malignant growths are encountered by them the time lost in this way before the necessity for proper advice is realized usually costs the patient's life.

E., 'Textbook of Surgery' (3d ed., Philadelphia 1915); Delafield and Prudden, 'A Handbook of the Pathological Anatomy and Histology' (10th ed., New York 1914), which contains a full bibliography; Bland-Sutton, John, 'Tumors, Innocent and Malignant' (4th ed., Chicago 1906); Hertzler, A. E., 'Treatise on

Tumors' (Philadelphia 1912); Scudder, C. L., 'Tumors of the Jaws' (ib. 1912); Virchow, Rudolf, 'Die krankhaften Geschwülste' (Berlin 1900); Von Bergmann and Bull, 'A System of Practical Surgery' (New York 1904); Tillmann's 'A Text-book of Surgery' (New York 1901); White, C. P., 'Pathology of Growth: Tumors' (New York 1914).

TUMULUS, an ancient artificial mound, often of large size, raised usually over the tomb of some prominent person. The custom appears to have been universal in the early historic period. As it required the use only of earth, and of rude stones for a sepulchral chamber, it was the only feasible method by which races in a low state of development could commemorate their dead, the tumulus was continued after architecture had made some progress. In ancient as in modern times, where large numbers of dead were heaped together, and it was desired to honor them all, the tumulus was the only monument that could be conveniently provided. The vast grave at Salisbury, N. C., in which thousands of Union dead are interred, is a tumulus as much as any of the great burial mounds of the ancients. Similar constructions are even now being heaped on modern battlefields.

The Bible and Homer give examples of tumuli. They are found in North America, Mexico, Central and South America, in Great Britain and Scandinavia, in Asia and Africa. They are not in all instances burial mounds. The Bible, in Genesis, xxxi 44–55, relates the erection of a "heap," or tumulus, as evidence of an agreement as to boundary between Laban and Jacob. It is probable that some of the mounds were ancient forts. That at Silbury Hill, Wiltshire, England, 170 feet high, may not have been a sepulchre, and some of the American mounds were sacrificial, and others may have been places of defense. Indeed all three uses — sepulchral, sacrificial and defensive — may have been included in a mound. It is also certain that some tumuli are simply residential ruins, the crumbled remains of adobe dwellings, or, in the desert regions of Asia and Africa, sand heaps rising as the sole memorials of vanished and once populous cities. See MEGALITHIC MONUMENTS; MOUND-BUILDERS.

TUMUT, tū'mŭt, Australia, a town in New South Wales, southwest of Sydney. It is in a mountain valley 1,050 feet above sea-level, on the slope of a hillside on the south bank of the river Tumut, from which the town takes its name. The Tumut does not dry up like most Australian rivers, during the hot weather, but remains at continual high water mark owing to the melting snows of the neighboring mountains, the loftiest of which is Mount Kosciusko, the culminating point of the entire continent. The town has four banks, four churches, schools and a lecture hall. Pop. about 1,200.

TUN. The old form of spelling for ton. It is still used to some extent for a cask or vat of liquor. See TON.

TUNA. See TUNNY.

TUNA, a cactus. See PRICKLY PEAR.

TUNBRIDGE (tŭn'brĭj) **WELLS,** England, in Kent, a watering-place and market-town, 35 miles southeast of London. It occupies detached hills with fine views and picturesque surroundings. At the end of the fine parade, the "Pantiles," are medicinal springs, which have been honored by royal and distinguished patronage since the 17th century. The common contains 170 acres. The principal buildings are a church, public and society halls, convalescent home for children, mechanics' institute, Nevill's club and pumproom. Tunbridge ware, consisting of fancy inlaid work or mosaics, is sold extensively. The original town of Tunbridge (pop. about 13,000), a wool-trade centre, is four miles to the north. Pop. of Tunbridge Wells about 35,000.

TUNDRA, toon'drą, the Russian name for the extensive low-lying, swampy peat-mosses which compose a considerable part of the great Siberian plain and that of North Russia. From June till the middle of August the tundras are thawed to a small depth, and are seen covered with mosses and lichens, among which there are sprinkled a few flowering plants. Many furred animals, along with various migratory birds, resort to the tundras for the short summer season.

TUNGSTEN (Wolfram), a metallic element found in the minerals scheelite ($CaWO_4$), wolframite [$(FeMn)WO_4$], hübnerite ($MnWO_4$) and ferberite ($FeWO_4$). It occurs in veins and in placer (q.v.) deposits. The most important occurrence is the placer tungsten of Burma. Portugal is also an important producer. In the United States, the important occurrences are in Bowlder County, Colo., San Bernardino County, Cal., and in the Black Hills of South Dakota. The pure metal is obtained by the Goldschmitt process (see THERMIT), that is, by the reduction of tungstic acid by aluminum filings; also by reduction of the oxide by heating with charcoal in an electrice or regenerative gas furnace. It is malleable and hard enough to scratch glass. Not acted upon easily by mineral acids. Atomic weight, 183.6; symbol, W; specific gravity, 16.6. It forms a number of compounds, among which are the chlorides WCl_2, WCl_4, WCl_5, WCl_6, the oxide WO_3, and the acid $WO(OH)_4$. Tungsten is used extensively alloyed with other metals, as iron and aluminum, to which it imparts very desirable properties. Tungsten steel is very hard and tough, highly magnetic, not easily rusted and has the valuable properties of self-hardening. The alloy of tungsten and aluminum known as partinium is very light and tough and is used largely in automobile construction. It is also used in incandescent lamp filaments. See MINERAL PRODUCTION OF THE UNITED STATES.

TUNGUSES, toon-goo'sĕz, a leading branch of the Mongol division of the Mongol-Tatar family, small in numbers but extending over a vast area from the Pacific in the west to the Yenisei River in the east. The race is found along most of the seaboard from Korea and Kamchatka, where a war was being carried on in 1904 between Russia and Japan. The Manchus, who conquered China, and are the rulers of that empire, are of Tungus stock, and from the same source came, in the remoter past, a large part of the savage and half-savage hordes that swept over lower Asia and western Europe. The Tunguses are now a dwindling race. Their morals are good, and their religion is chiefly the aboriginal Shamanism, although

some have been converted to Christianity and Buddhism. Their name is said to be derived from a Chinese word signifying "people." The Tunguses on the higher Pacific Coast are called the Lamuts, or "sea-people," and those in the vicinity of the Amur and Korea are called by the Russians the Tazi. The Tunguses, exclusive of the Manchus, are estimated at about 80,000 in number, of whom about 15,000 are in the Amur Basin, and the others in Siberia. See MONGOLIAN RACE; SIBERIA; TUNGUSIC.

TUNGUSIC, a language spoken over hundreds of thousands of square miles of Asia, by the people known as Tunguses. Manchu is a dialect of this language. It is a Mongol tongue, of a low grade of development, having no verbs, and possessing no distinction of number and person in the predicative words. See TUNGUSES.

TUNGUSKA, rivers of Siberia. The three large rivers of Irkutsk, which unite to form the Yenisei are known as the Upper, Middle (or stony) and Lower Tunguska. They drain an area of about 800,000 square miles. The Upper and the Lower Tunguska are each rivers about 1,800 miles long, and they unite at Turukhansk, just south of the Arctic circle. The upper branch drains Lake Baikal. See SIBERIA.

TUNIC, an ancient form of garment in constant use among the Greeks; a sort of short-sleeved shirt. Among the Romans the tunic was an under garment worn by both sexes (under the *toga* and the *palla*), and was fastened by a girdle or belt about the waist. The woman's tunic was often long like the modern chemise. Soldiers often wore the tunic without the toga, as some workmen to-day wear a blouse. When ornamental, it sometimes became an article of ceremonial dress, as the purple-bordered *laticlavus* of senators. The Anglo-Saxons of the Middle Ages also wore a tunic, much like a skirt, and often tied at the waist. The term is also used ecclesiastically to denote a dress worn by the subdeacon, made originally of linen, reaching to the feet, and then of an inferior silk, and narrower than the dalmatic of the deacon, with shorter and tighter sleeves.

TUNICATA, or UROCHORDA, a class of animals of the phylum *Chordata* (q.v.), commonly represented by the Ascidians (q.v.) formerly much misunderstood. Since Kowalewsky's description in 1866 of the development of an ascidian, it has been clear that these animals, together with all the other tunicates, must be associated in the zoological system with Amphioxus and the true vertebrates. Most tunicates pass through a free-swimming, tadpole-like, larval stage (and a few remain permanently in this condition) which has in the tail or swimming organ a notochord and a tubular central nervous system, both of which develop in essentially the same manner as in other vertebrates. The fore part of the alimentary canal is perforated by pores or stigmatæ opening to the exterior and serves as a respiratory organ. After a short free-swimming period, the larva attaches itself in typical cases and the tail is gradually absorbed with its contained organs, so that both notochord and tubular nerve cord disappear, a remnant of the latter in the body becoming the ganglion of the adult. The *Tunicata* comprise three orders: The *Larvacea,* including forms of small size and simple structure, which retain the larval tail throughout life. *Appendicularia* is an example found abundantly among the surface fauna of our coasts. The *Thaliacea,* including almost exclusively free swimming pelagic forms which have no tail in the adult and seldom a tailed larvæ. They form compound colonies and exhibit an alternation of generations. *Salpa* (q.v.) is an example. The *Ascidiacea,* including usually fixed, simple or compound forms, with usually well-marked larvæ, but no tail in the adult state. *Molgula cynthia, Boltenia* and *Amaræcium* are common genera on our coasts. See ASCIDIAN. Consult Herdman, 'Challenger Reports,' Vols. VI and XIV, London (1882 and 1886); Verrill, 'Invertebrates of Vineyard Sound' (Washington 1874).

TUNING. See REED, FLUE AND STRINGED INSTRUMENTS, TEMPERAMENT, TUNING AND VOICING OF.

TUNING-FORK, *in music,* a piece of steel having two parallel forks or prongs of equal dimensions, constructed and tempered so as to give a definite note when caused to vibrate. Tuning-forks are small and easily carried in the pocket. They may be sounded by striking against any convenient solid object. Large tuning-forks are used for lectures on acoustics, fixed on sounding-boxes, and caused to vibrate with a resined hair-strung bow.

TUNIS, tū'nĭs (AFRIKIYA), North Africa one of the old Barbary States on the Mediterranean coast, formerly tributary to Turkey, and now a French protectorate, bounded on the north and east by the Mediterranean Sea, on the south by Tripoli and on the west by Algeria. It extends about 400 miles from north to south, 150 miles from east to west and has an area of 38,450 square miles. The coast is indented by the three large gulfs of Tunis, Hammamet and Gabes. It is bordered by a low, sandy and desert region in the east and by precipitous mountains in the north. The northern part of the country is a plateau, becoming very mountainous in the extreme north. The southern part is a flat steppe region, lying partly below sea-level, and containing large tracts of salt marsh. The principal river is the Mejirda, in the north. The northern mountains are covered with large oak forests, and contain very fertile valleys. The principal minerals exploited are salt, nitre and phosphates, iron, lead and mercury. Large numbers of cattle, sheep, camels and fine horses are raised. Agriculture is less developed, though climate and soil in the north are favorable. There is some vine and oil culture, and considerable fisheries along the coast, but the industries are not important. The principal commercial ports are Tunis-Goletta, Susa and Sfax. The chief exports are vegetables, oil, phosphates and mineral ores, esparto-grass, livestock and cattle products, sponges, dyes and fruits. The total value of exports in 1916 was $23,750,000, and of imports $26,850,000. The head of the immediate government is the native bey, who rules under French protection. The capital is Tunis. The population is of a very mixed character, containing, besides the Moors, traces of the ancient Numidian, Phœnician and Roman elements. The total population is about

1,906,000. In 1918 there were 48,000 French and 130,000 other foreigners, including 112,000 Italians. Tunis was a part of the ancient Carthaginian dominion, and afterward of the Roman province of Africa. In the latter part of the 7th century it was taken by the Arabs, and in 1575 it came under Turkish suzerainty. In 1881 France invaded Tunis under pretext of punishing the Krumir marauders. As a result of the invasion the bey was forced to sign the treaty making the state a French protectorate.

Education.— There are about 287 public schools, eight lycées and colleges and 23 private schools. There are 30,767 pupils of whom 18,731 are boys. Of all pupils, 7,025 are French, 9,639 Mussulman; 4,870 Jews, 9,639 Italian; 1,570 Maltese and 280 others. In the Great Mosque at Tunis there is a Mohammedan university. In the city are 86 and in the interior 1,214 Mussulman primary schools, some of which receive state-aid.

Government.— The government is carried on under the direction of the French Foreign Office, which has a special department for Tunisian affairs, under the control of a French Minister Resident-General, who is also Tunisian Minister of Foreign Affairs, and a ministry of 10 heads of departments, eight of whom are French. French tribunals take cognizance of cases between Europeans and between Europeans and Tunisians, and there are native courts for cases between natives.

Finance.— The 1916 revenues aggregated $12,843,245, made up from direct taxation $2,278,845, indirect taxation $3,878,180, monopolies (tobacco, etc.) $4,384,385, post office, telegraphs, etc., $607,095 and royalties, etc., $1,694,740. In the same year the disbursements amounted to $12,283,945, for the civil list the residency and district services, public debt charges, the various government departments and the army. The public debt is about $450,000,000.

Communications.— About 2,000,000 tons of shipping enter and clear annually at Tunisian ports. About 37,962 miles of good roads have been constructed within the last 30 years. There are in operation 1,535 miles of railway, 3,721 miles of telegraphs, 254 telegraph offices, which handle annually about 1,700,000 messages. There are 724 miles of urban telephone lines and interurban systems with 2,717 miles of wire. There are 456 post offices, which in 1916 handled 41,077,660 letters in the internal service, and 71,111,196 in the external service.

Defense.— There is an army of occupation maintained by France, and having an average strength of 17,000 to 18,000, with 600 officers. There are a few native regiments (*spahis*, etc.) included in this force. In the Great War 1914–18 about 35,000 Tunisian troops served under the tricolor in France.

Bibliography.— *Journal officiel Tunisien; Foreign Office Reports* (London annually); *Annuaire Statistique de Tunisie* (Paris); Besnier et alii, 'La Tunisie au début du XXe siècle' (Paris 1904); Bloesch, H., 'Tunis' (Berlin 1916); Geft, L., 'La Tunisie economique' (Paris 1910); Hesse-Wartegg, Chevalier de, 'Tunis, the Land and the People' (2d ed., London 1899); Lanessan, de, 'La Tunisie' (Paris 1917); Thomas, P., 'Essai d'une description géologique de la Tunisie' (Paris 1908); Vivian, H., 'Tunisia and the Modern Barbary Pirates' (London 1899).

TUNIS, North Africa, the capital of the French protectorate of Tunis, situated in the northeastern corner of the country, at the western extremity of a shallow salt lagoon connected with the Bay of Tunis by a narrow channel at the port of Goletta. A canal, six and one-half miles long and 22 feet deep, has been dredged through this lagoon to Tunis. There is a good water supply provided by rebuilding an ancient aqueduct. The interior of Tunis presents generally a labyrinth of narrow dirty streets; but great changes have taken place since the French occupation, a European quarter with fine buildings, including the French residency, the public offices, Roman Catholic cathedral, etc., having arisen. Besides the colleges, there are good hospitals and a large asylum for the aged, maintained by the Little Sisters of the Poor. Among the most interesting native buildings are the bey's palace and the mosques. The city has considerable manufactures of silk and woolen goods, shawls, mantles and jewelry. There is now regular steam communication with Europe and the ports of Algeria, and a railway runs to Algiers. The ruins of ancient Carthage lie about 10 miles to the northeast of Tunis, and may be reached by railway. Pop. about 164,606 Moslems, 43,000 Jews, 70,000 Italians, French, etc; total, 277,606.

TUNKERS. See DUNKARDS; GERMAN BAPTIST BRETHREN.

TUNKHANNOCK, Pa., county-seat of Wyoming County, on the Susquehanna River and the Tunkhannock Creek, and the Lehigh Railroad. It is 30 miles northwest of Wilkes-Barre. Lumbering is carried on extensively, and the chief industries are tanning, spool and tub factories, stave and planning mills and furnaces and machine shops. There also are witchhazel distilleries. Pop. about 1,800.

TUNNELS, Great Modern. The completion of the boring of the Simplon tunnel on 24 Feb. 1905, thus assuring of its being opened to travel during the latter part of that year, marked the culmination of one of the greatest events in civil engineering during the last decade, and the successful termination of the greatest tunnel boring enterprise of any age, ancient or modern.

At the present time, four great tunnels pierce the great Alpine barrier between northern and southern Europe. The Mont Cenis and the Saint Gotthard connect France and Italy; the Arlberg places Austria in communication with Italy, while the Simplon forms a direct connection between Italy and Switzerland, bringing Geneva and French Switzerland into closer communication with Milan and the Adriatic railways. It also shortens the distance from Calais to Milan by 95 miles, as compared with the Mont Cenis route, and by 80 miles over the route passing through the Saint Gotthard.

The feasibility of a transalpine tunnel was contemplated about the middle of the 19th century, and work was begun on the Mont Cenis tunnel in 1857, at a point near Modane in France, from which it passes under the elevation, Col de Frejus, about 18 miles west of Mont Cenis, and emerges into Italian territory

at a point near Bardonecchia, 24 miles from Susa. The exact length of the tunnel between portals is 7.6016 miles, but as the railway, instead of entering the tunnel at the portals, joins it through special curved sections at each end, the total length of the borings amounts to about eight miles. It was bored simultaneously from both ends on a rising gradient, with its summit at the middle point. The grade from Modane is about 1 in 2,000. The rock formation traversed as the boring advanced southward from Modane was characterized by carbonaceous schist 1.3027, quartz 0.2414, limestone 0.2210, and calcareous schist 2.0357 miles; while the entire distance traversed from the Bardonecchia end to the summit amounting to 3.800 miles, was through calcareous schist. The altitude of the tunnel is about 4,248 feet above sea-level, and 5,428 feet below the crest of the mountain. At the Modane end the tunnel is 25 feet 3½ inches wide at the bottom, 26 feet 2¾ inches at the point of maximum breadth; semi-circular in form, and 24 feet 7½ inches in height. At the Bardonecchia portal, an elliptical arch is introduced to resist the greater strain caused by the different inclination of the strata, and the height is 11¾ inches greater than that of the Modane section. The side walls are eight feet six inches in thickness throughout the entire length of the tunnel, and with the exception of 300 yards on the north side, are lined with brick and stone, while the side paths are paved with flagstones 20 inches in width. During the first three years, the operations consisted of hand labor exclusively, but in 1861 and 1862 power drills were installed at the Bardonecchia and Modane ends, respectively. The drills employed were designed by Sommeiller, the chief engineer. They were of the percussion type, the operative power being compressed air. Gas factories and machine shops were installed at each end. During the boring process, many springs were tapped, the water from which found an outlet through the tunnel. This water was finally utilized to furnish the power for the air compressors operating the drills — the Italian engineer profiting by the suggestion of the invention by Bartlett in 1855, of a rock drill operated by air compressed by a steam engine. The air compressing apparatus was installed at the Italian end, the compression approximating six atmospheres, derived from the hydraulic pressure from mountain streams and the water from the tapped springs. The same apparatus supplied fresh air at the rate of 2,000 cubic feet per minute, while the ventilation was accomplished partly by the atmospheric drills, and partly by special ventilating pipes eight inches in diameter, the blowers and exhausting bells being operated by powerful turbines. Gunpowder was exclusively used in the blasting operations, the charges being fired by a magneto-electric apparatus in front of a movable bulkhead, which was advanced as the work progressed, the detritus being subsequently removed by hand, by gangs of men 900 feet apart, working on scaffolds at various heights. The hauling was accomplished by horses and small trucks. The credit of the work belongs to the three Italian engineers, Sommeiller, Grandis and Grattoni, whose genius surmounted the many obstacles which daily confronted its advance. The boring of the tunnel was finished in 1870, and it was opened to traffic in 1872, equipped with a double-track railway and cost $1,100 per linear yard, a total expenditure of $15,000,000, and required 13½ years for the accomplishment of an engineering task, which was the greatest in its time. The entire undertaking was financed by the Sardinian government. It is an example of tunnel construction by the drift method.

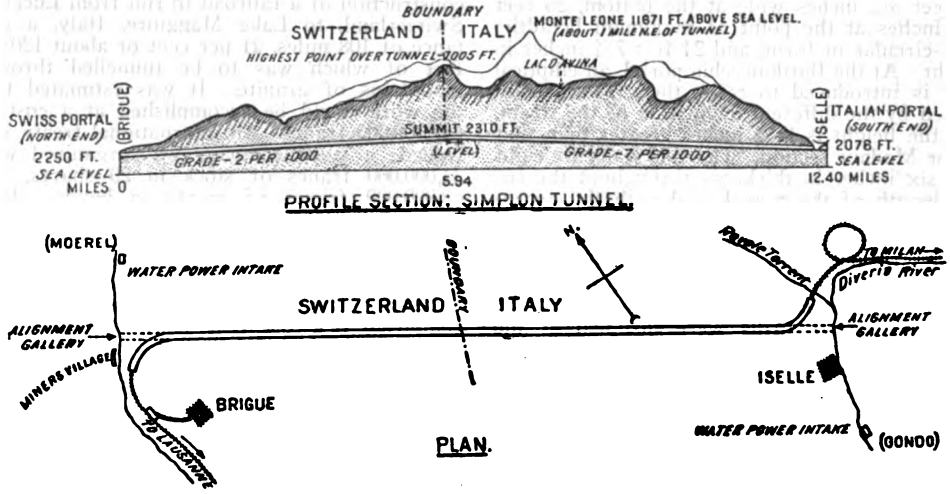
Immediately following the opening of the "Mont Cenis" for travel in 1872, a work of much greater magnitude was undertaken not only to make another connection beween France and Italy, but to connect the North Sea ports with those of the Mediterranean; those of Belgium, Holland and Germany, with Genoa; and the Valley of the Rhine with that of the Po. The enterprise was too great for private industry or capital, therefore, in 1871 Italy, Germany and Switzerland voted large subsidies for the construction of a railroad to run from Lucerne, Switzerland, to Lake Maggiore, Italy, a distance of 108 miles, 21 per cent or about 120,000 feet of which was to be tunnelled through mountains of granite. It was estimated that the work could be accomplished at a cost of 187,000,000 francs. An international treaty was signed; a stock company was organized with 34,000,000 francs of stock in 20 shares, and 68,000,000 francs of mortgage bonds. Italy gave 45,000,000 francs, and Germany and Switzerland each 20,000,000 francs. This estimate, however, was found to be too low by 102,000,000 francs, and caused a great many unnecessary delays in the work, which was finally completed at a cost of 289,000,000 francs ($57,800,000), of which $11,500,000 was expended on the Saint Gotthard tunnel alone, the location for which in spite of many undesirable topographical conditions was selected at the most central point of the Alpine range, on account of the directness of the route thus obtained. The northern portal is situated near the little village of Goeschenen in the canton of Uri, Switzerland, from which the axis of the tunnel passes through the range under the lofty peak known as Col de Saint Gotthard, and emerges from its southern portal near Airolo in the canton of Tessin, Italy, after traversing a direct distance of nine and one-quarter miles, and forms a part of the railway from Lucerne to Chiasso.

Unlike the case of its predecessor, the Mont Cenis, the tracing of its axis was beset by a great many difficulties, due to adverse topographical conditions. The axis of the Mont Cenis was traced under the mountains by means of three astronomical observatories, one being established at a high elevation and equipped with a telescope that revolved in the vertical plane passing through the axis of the tunnel. From this station the position of the other two observatories were determined toward the entrances, their telescopes placed in the same vertical plane, and the direction of the axis supplied to them whenever necessary. The direction of the Saint Gotthard was determined by careful triangulation; the fine topographic maps of Switzerland forming an important and valuable adjunct to the operations. Owing to the great elevation at which the tunnel was driven, that of the north and south portals being respectively 3,639 feet, and 3,757 feet above sea-

level, seven sets of helical or spiral tunnels, four on the Italian, between Giornico and Fiesso and three on the Swiss side, were constructed to bring the railway up to the great elevations of the portals. This system, designed by Hellwag, the engineer-in-chief, comprised a series of 100 tunnels in all, some of which are 6,000 feet or more in length, making the total distance tunneled slightly less than 23 miles. Under these conditions, the trains enter the foot of the mountains and by winding about through the spirals within its bowels, emerge along its sides a couple of hundred feet higher up at each lift until the entrance to the main tunnel is reached. The travelers are thus afforded successive views of the magnificent Alpine scenery from various altitudes, passing within a few hundred yards of Rutli, Bürglen, Altdorf and other spots made famous by William Tell, and

ally. The force of laborers numbered 3,500 all Italians, while the officers were Swiss and Germans. The men were paid from three to six francs per day of eight hours' work, and had to board themselves. Under these circumstances the poor food with which they supplied themselves contributed greatly toward the enormous death rate. Favre (Swiss) was the head of the firm of contractors. The cross section dimensions of the boring is similar to that of the Mont Cenis, and is lined throughout with masonry 18 to 20 inches in thickness. It is equipped with a double-track railway, and required nine and one-half years of labor for its construction, which was commenced in 1872 and completed in 1882.

The third great Alpine tunnel, the «Arlberg,» forms a part of the Austrian railway between Innsbruck and Bludenz in Tyrol, which con-



through the intricacies of the rugged Axenstrasse. Salient facts relative to the construction of this tremendous piece of engineering may be briefly stated as follows: The work was prosecuted under the Belgian system, main heading; rock drills being operated and ventilation accomplished by water power exclusively. At the Swiss end, 1,220 horse power was derived from the Reuss River by means of four horizontal impulse turbines, and at the Italian end, 1,220 horse power, from the combined heads of the Tessin and Tremola rivers, by means of six turbines of the same type. These turbines working in pairs, drove groups of Colladon air compressors, which supplied 1,000 cubic yards of air per hour at a compression of seven to eight atmospheres, equal to 100 horse power, delivered at the drills, which, when exhausted, equaled 8,000 cubic yards of fresh air per hour. Dynamite was exclusively used in the blasting operations, being considered cheaper and safer than nitroglycerine. At first the arrangements for ventilation were very inadequate, and combined with a lack of proper sanitary and hygienic regulations, resulted in a great loss of life. The application of the injector system of ventilation, invented by Signor Saccardo, engineer of Bologna, rectified these conditions materi-

nects westward with the Swiss railroads, and southward with those of Italy. It penetrates the Alpine watershed between the Rhine and the Danube, from Saint Anton to Langen, a distance of 10.25 kilometers, about six and one-third miles, its axis passing 1,594 feet under Arlberg Pass. The eastern and western portals are respectively 4,277 feet and 3,985 feet above sea-level, with the summit at an elevation of 4,301 feet. Its construction was begun in 1880 and completed in 1883, at a cost of $7,500,000. Passenger trains pass through the tunnel in about 25 minutes.

Many schemes to connect Switzerland and Italy by a railway near the Simplon Pass had been in contemplation for several years. In 1881 the Jura-Simplon Railway advanced the scheme of piercing the Alpine barrier by a tunnel, which entering the base of Monte Leone at a short distance above Brigue, situated on the Switzerland side, on the left bank of the Rhone, and passing under the lofty mountain range, would emerge at Iselle on the Italian side, the distance to be traversed being somewhat over 12 miles. Since the days of the Roman Empire, the Simplon Pass has been the trade route between Milan and the flourishing cities of the Valley of the Rhone. For more than 2,300 years it was the great highway of trade and travel

between southern and northwestern Europe. Over it, Hannibal led the conquering armies of Carthage, and, later, Cæsar his legions, when he laid the foundations of the Roman Empire. In modern times the Jura-Simplon Railway has run its trains along the same route, although laboring under the almost prohibitory difficulties of excessive grades and the long distance compelled by the ruggedness of the rock formation on the Swiss side of the frontier. The Swiss and Italian governments considered the scheme proposed by the Jura-Simplon Railway Company favorably and undertook its financing jointly. The Swiss government entrusted the work of construction to the Baugesellschaft fuer Simplon-tunnel, Brandt Brandau and Company extending to it a credit of $13,000,000, stipulating that the entire work should be completed in five and one-half years, the limiting date being stated as 21 May 1904. For each day that the work was finished prior to that date the company was to receive a premium of $1,000, and for each day of delay subsequent to that date it was to be fined a similar amount. The price named, however, was greatly exceeded, the actual cost finally amounting to $15,700,000; the additional payment and the extension of time for completion being agreed to by the governments interested, on national grounds as well as in due recognition of the many unexpected difficulties that confronted the contractors and caused unavoidable delays. For example, although the advancement of the tunnel averaged between 500 and 700 feet per month, an advance of only 50 feet was made during the first three months of 1902, the work being retarded by the tapping of many springs and by the occurrence of numerous rock-slips.

The first blast in the work of boring was fired 21 Nov. 1898, the operations being carried on simultaneously at both the Swiss and Italian ends. In order to avoid the excessive freight rates compelled by the expensive operation of the traffic over the inclines of the Saint Gotthard, as well as for the purpose of making it an express route operating fast-train service, the altitude of the tunnel was kept as low as possible, although it might have been driven at a much higher level with an enormous saving in the cost. The Swiss end has an altitude of 2,250 feet and the Italian end 2,076 feet above sea-level, while the summit of the tunnel, where the ascending gradients from each end meet, has an altitude of 2,310 feet.

This tunnel, unlike the other transalpine borings, which are single passages equipped with double tracks, consists of two parallel tubes or twin passages, each 16½ feet wide, separated by a distance of 55.7 feet between their axes, each passage being equipped with a single track, thus permitting of travel in both directions at the same time. It is straight throughout its entire length with the exception of a short curve at each extremity, so that the new railway running from Brigue and gently ascending the valley of the Rhone for a distance of one and one-fourth miles, enters the tunnel on a right curve of 1,050 feet radius. The straight portion of the tunnel begins at a distance of about 460 feet from the entrance, extends a distance of 12¼ miles, at an obtuse angle with the Rhone Valley in Switzerland and the Val Vedro in Italy, and emerges on a left curve of 1,311 feet radius, above the banks of the Diveria River, on the Italian side. It has rising gradients of two per 1,000 from the Swiss side and seven per 1,000 from the Italian entrance, the summit of the tunnel or the meeting point of the gradients being at a distance of 5.944 miles from Brigue, at an altitude of about 2,310 feet above the level of the sea, and about 7,000 feet below the crest of the mountain between the Furggenbaumhorn and the Wasenhorn. The two passages are connected by transverse galleries or cross-headings at intervals of 660 feet, thus facilitating ventilation and problems of transportation. At the summit the transverse gallery is excavated to double width and affords room for the central station located at that point.

The working force numbered 1,000 men, divided into three shifts on the eight-hour basis, so that the work was carried on continuously day and night during the entire period of over six years. These laborers were all Italians, the Swiss having no adaptability to the work of blasting rocks and removing debris, thousands of feet below the snow-capped mountain ranges or the verdant hills upon which they tended their herds and crops. This small army of workmen was comfortably located in well-arranged quarters which were erected across the river near the Swiss portal, and every necessary precaution was taken to protect their health and keep them in a fitting condition to prosecute their labors. The many fatalities consequent to a lack of these precautions in the construction of the Saint Gotthard afforded an example by which the Simplon management profited greatly. At the Swiss end they established a fine hospital with facilities for treating emergency and contagious cases. Sanitary and hygienic regulations were strictly enforced. When a shift of laborers was relieved and came out of the hot workings in the tunnel, each man was required to take a bath at once, before being exposed to the keen Alpine atmosphere, and he was required to hang his damp working clothes in a drying room, and put on another suit while he was off work. As the Simplon boring was executed at a depth ranging from 5,000 to 7,000 feet below the surface of the mountains, about 50 per cent deeper than had ever been required previously, the engineers were compelled to devise means to ameliorate the resulting conditions of torridity, in which the temperature frequently rose to 110° F. These conditions were modified by pumping cold water from the outside into the boring through pipes pierced with small holes, so that the water fell upon the laborers like a fine rain or drizzle, and through this liquid veil the fresh air was forced and cooled to a bearable temperature. The general refrigeration was effected by means of 34,118 feet of 9.96 inch piping from each end, connected to four refrigerating appliances of 71 heads and 11 jet sprays placed at intervals along the boring, so that the spray would bathe all the sides of the headings in the neighborhood of rock heated to a temperature by infiltration from hot springs, the waters of which were of a parboiling temperature and often exceeded 112° F. The plan of carrying away the hot water to some point where its effect would not cause the same local inconvenience was uniformly pursued, but only partially prevented the heating of the air, although the greatest care was

taken to insulate the pipes both from hot and cold radiations. Ventilation was accomplished with the aid of the auxiliary tunnel, No. 1. It is to be understood that of the twin passages, the one designated as No. 2 was completed first, that is, enlarged from the heading to its ultimate dimensions, passage No. 1, at first being carried on with much smaller dimensions, and forming an important adjunct in the system of ventilation. The compressed air for this purpose and for operating the compressed air locomotives was carried through tunnel No. 1, to the headings through pipes varying from 1.18 to 1.97 inches in diameter; air valves on the main at various points enabling the recharging of the locomotives. When the heading face was some distance in advance of one of the transverse galleries cool air was supplied to a nearby point through a light sheet-iron pipe carried immediately below the roof of the heading. At intervals a connection was formed between the hydraulic pressure main running along the floor of the heading, so that a jet of air was forced into the overhead pipe under a pressure of about 78 atmospheres, inducing a strong current in the pipe which was conducted right up to the face. The water was collected in and drained off a number of siphons placed at intervals along the air main. During the last two years of the work compressed air locomotives were exclusively used at the Swiss end as the use of horses for switching the spoil trucks at the headings was made impossible by the heat of the tunnel. An important feature of the entire work was the fact that no possible advantage that could be derived from transported hydraulic force was neglected. The water discharged from the tunnel from tapped hot springs and infiltrations amounting to 50 or 60 gallons per second was utilized to operate the ventilator turbines, as also the return water pumped into the tunnel for power to drive the rotary drills and for purposes of refrigeration.

The rock-boring work was accomplished with an hydraulic perforator, a machine consisting of a hollow steel stem, two and three-fourths-inches diameter, carrying on its end the three tempered cutting points. It was operated by a hydraulic engine with a pump pressure ranging from 80 to 120 atmospheres, representing an available force of 22,000 to 26,000 pounds. During operation water was constantly forced through the hollow stem, and while washing away the débris tended to keep the teeth cool. The teeth biting into the rock wore it away at the rate of about one-third an inch per revolution, the number of revolutions varying from four to eight per minute according to the hardness of the rock. From 10 to 12 machines were in operation at each end of the tunnel from the start. When the drills had penetrated to the depth of about five feet they were withdrawn, the dynamite was inserted and fired and the spoil cleared away.

Perhaps the greatest of all of the difficulties encountered in the prosecution of this work was the influxes of hot water, first on the Swiss and later on the Italian side. Professor Schardt, the official geologist, estimated that the tunnel discharged one billion cubic feet of water during its construction. At times the boiling springs tapped converted the boring into a veritable canal, forcing a suspension of operations for months at a time, until the water was gotten under control, pumped out and the walls of the tunnel sufficiently cooled by sprays of ice-water to allow the men to resume work. Even then they had to be sprinkled constantly with ice water to enable them to withstand the deadly temperatures. These conditions forced the abandonment of the operations on the Swiss side at a point about six miles distant from the entrance, the necessity for the suspension of operations being materially augmented by a landslide which occurred at Moerel, a point on the Rhone, a short distance above the intake of head-water which supplied the hydraulic force for the power station at Brigue. The work was then carried on from the Italian end and advanced regularly at the rate of about 16½ feet per day, until 6 Sept. 1904, when a gigantic boiling spring was tapped which discharged into the tunnel a stream of water with a temperature of 113° F. at the rate of 1,600 gallons per minute. The rock temperature was forced up to 108° F., and the work had to be stopped until a transverse gallery could be constructed to join the two southern passages so as to allow the hot water to flow out of the main passage through a lateral canal along its walls. The temperature was cooled by jets of ice cold water, and after a delay of three months, during which the work of enlargement was accomplished, the heading was pushed forward resulting in a junction of the northern and southern tunnels 24 Feb. 1905, allowing the immense volume of water which had accumulated in the headings of the abandoned north tunnels to flow down through the main south tunnel into the Diveria River.

The machinery installed at both ends of the tunnel was mainly of European manufacture. It consisted of four-stage high-lift centrifugal pumps and hydraulic turbines at the power stations, centrifugal pumps driven by Pelton wheels in the swamped portions of the tunnels; duplicate 12¼-foot ventilating fans, which will continue to serve all the requirements of the tunnel under operative conditions, driven by two 200 horse-power hydraulic turbines. High-pressure plunger pumps in connection with the hydraulic accumulators, each pair of pumps being driven by a Pelton wheel, supplied cold water to 16 Brandt hydraulic borers working at both ends of the tunnel, four at each heading face. The high-lift refrigerating centrifugal pumps were run in series at 950 revolutions per minute, under a pressure of 370 pounds per square inch and supplied water to the refrigerating plant at the rate of 18.21 gallons per second. The refrigerating conduit also furnished power for four ejector pumps and six portable fountain heads located in the traversing galleries. In the beginning steam locomotives were employed for hauling, and steam engines were kept in reserve to be used in case of the failure of the water power; but as the work advanced compressed air locomotives were used exclusively at both ends of the borings. The air compressors had a capacity of two and three cubic meters of free air per minute and compressed air into a reservoir of the tubular battery type. The machinery installations at both ends of the tunnel were identical.

A very clear idea of the difference in the amount of time and labor consumed in the bor-

ing of ancient and modern tunnels may be obtained by comparing the Roman tunnel bored for the purpose of draining Lake Fucino with the Simplon. The former, begun in the reign of Julius Cæsar, was completed during that of Claudius 52 A.D. It was three and one-half miles long and passed under the Palatine at a maximum depth of 400 feet. Its construction involved the sinking of 40 vertical shafts and many inclined galleries, requiring the labor of 30,000 men during a period of 11 years. It was the most celebrated work of its kind at that time and still remains in an almost perfect state of preservation.

On the other hand, the Simplon tunnel with its twin passages 12¼ miles in length, repreesening 24½ miles of boring, at a depth often exceeding one and one-quarter miles below the surface, required the labor of 1,000 men during a period of about six and one-half years. The Fucino tunnel has a normal cross section 10 feet high by 6 feet wide; with the appliances used in the work of the "Simplon" it could have been easily bored in six months.

Another important European tunnel was completed in 1916 despite the war. It is known as the Rove tunnel and runs from l'Estaque, France, to make way for a canal from Marseilles to the Rhone River. It is four and one-half miles long, 72 feet wide and 47 feet high, and it is wonderful that the French were able to complete it at such a time.

In 1906 work was begun on a tunnel under the Loetschen Pass from Bern to Brig, Switzerland. It is nine miles long and was opened in the summer of 1913. Other long Swiss tunnels are those at Côte d'Or, begun in 1915, and the Jura tunnel between Munster and Grenchen, the latter five and five-eigths miles.

The only American tunnel previous to 1900 comparable to the transalpine borings already described is the Hoosac tunnel on the line of the Fitchburg Railroad, between Troy, N. Y., and Greenfield, Mass. It is driven through a southern spur of the Green Mountain range, known as Hoosac Mountain, and is 25,037 feet (four and three-fourths) miles in length. Its construction was begun in 1855 and completed in 1873, the masonry work requiring several additional years. During this period the work was suspended many times on account of a lack of funds and the natural obstacles encountered. Where the rock is solid, it is 20 feet high and 24 feet wide, but wherever arching was necessary these dimensions are somewhat greater. The work was carried on by four headings, one from each end and two from an intermediate shaft 1,028 feet in depth; modern tunnel boring methods, involving the use of electricity, nitro-glycerine, air compressors and power rock drills and marking their first introduction in America. It has an ascending gradient of 26 4/10 to the mile, is equipped with a double railway track and cost a little less than $11,000,000. Slightly longer is the Rogers Pass tunnel (26,400 feet) on the Canadian Pacific Railway in the Selkirk Mountains of British Columbia. It is 24 by 29 feet, concrete lined. What will be the longest American tunnel is the Continental Divide, being cut under the Rockies for the Denver and Salt Lake Railroad, six and one-half miles in length. The longest up to the date of opening (1909) was the Gunnison in southwestern Colorado, six miles in length.

The lengths of some of the other important mountain tunnels in various parts of the world are as follows: the "Giovi" on the Genoa-Ronco Railway, 8,260 meters (about five and one-sixth miles); the "Marianopoli," on the railway from Catania to Palermo, in Sicily, 6,840 meters (about four and one-quarter miles); the "Sutro" in Nevada, 6,000 meters (about three and three-fourths miles); the "Standridge," between London and Birmingham, 4,970 meters (a little more than three miles); the "Nerthe," between Marseilles and Avignon, 4,620 meters (a little more than two and three-fourths miles); the "Pracchia Tunnel," on the main railway line between Florence and Bologna, through the Apennines, comprising 52 tunnels with heavy gradients — 25 per 1,000 throughout, the several tunnels varying in length from 3,000, 6,000 to 9,000 feet, characterized by very poor ventilation, which was finally improved by adopting the Saccardo system, which was here applied practically for the first time. The "Bilbo" in Italy, 4,240 meters (a little over two and one-half miles); the "Kaiser Wilhelm," on the Moselle Railway, near Kochem, 4,220 meters (it is the longest tunnel in Germany); the "Blaisy," on the railway from Paris to Lyons, 4,100 meters (two and one-half miles); the "Stampede," on the Northern Pacific Railway, 9,850 feet, and the "Cascade," on the Great Northern Railroad, 13,413 feet in length, through the Cascade Mountains in the State of Washington. The construction of the former was begun in 1886 and completed in 1888; that of the latter covering the period between 1897 and 1900, the cost of each being about $1,250,000. Both of these tunnels pierce the mountains at a considerable elevation, about 3,000 feet above sea-level, but are surpassed in this particular, and the technical difficulties of construction encountered, by those of the transandean railways, the most notable of which was opened in 1892, on the Peruvian Central Railway, running from Callao to the Pacific Ocean, thence by way of Lima to Oroya on the eastern slope of the Cordilleras. This line after passing the station Sureo on the Chalappa Viaduct at an elevation of 6,650 feet overcomes the great topographical difficulties of the Matacana Valley and passes through the tunnel, 3,596 feet long, at a height of 15,781 feet above sea-level — an elevation equal to that of Mont Blanc, the highest peak of the Alps — in a region of perpetual snow, 104 miles from Callao. Another one, 15,880 feet in length and forming a part of the railway between Buenos Ayres, Argentina and Santiago, Chile, pierces the Andean range at an elevation of 10,500 feet above the sea. In 1910 another transandean tunnel was completed, connecting Valparaiso and Buenos Ayres and cutting the mountains at an elevation of 10,000 feet. Australasia has but one remarkable tunnel, that at Otira, New Zealand, five miles in length.

The most notable of the many other examples of mountain tunnels are: the "Stone Mountain Tunnel," at Gibraltar, a series of galleries three miles long, pierced for cannon at intervals of 12 yards and having guns of large calibre already mounted in 1,000 of these embrasures. The "Joseph II Mining Adit," forming the main efflux gallery of the metal and

sulphur mines at Schemnitz, Hungary. It was begun in 1782, the time required for construction being estimated at 30 years and the cost at 1,215,000 florins. The progress of the work, however, suffered a great many delays and it was not completed until 1878, the total expenditure amounting to 4,599,000 florins. It is 9 feet 10 inches high, five feet two inches wide and is the longest mining tunnel in the world, having a length of 10¼ miles. The «Kojak,» forming a part of the Northwestern State Railway of India, about two and one-half miles long, and completed in 1891. The «Tequixquiac,» a boring 14 feet in diameter, driven through sandstone for the purpose of draining the Valley of Mexico. It is six miles long and cost $6,760,000. The drainage works designed to improve the sanitary condition of the City of Mexico and prevent the inundation of its streets, for long periods at a time, by the overflow from Lake Texcoco and the consequent loss of thousands of lives, were begun during the latter part of the 16th century. Up to 1789 the work was of an intermittent character, cost many thousands of lives and many millions of dollars. From 1789 to 1830 the effort was more sustained and systematic but, although $8,000,000 had been expended, and the city protected from the inundations, its position in the bottom of a basin without natural drainage, with the artificial drainage canal inadequate in depth owing to its being controlled by the level of the lake which was but slightly lower than that of the city, continued to keep it subject to virulent epidemics of malaria. The new works, gigantic in character and ranking with the greatest of modern engineering accomplishments, were begun in 1885 and completed in 1900, with a total expenditure of $20,000,000. These works consist of a complete sewerage system within the city; a system of sewers to control the overflow of the entire valley; a canal 43 miles long, connected with the sewerage system, at the Saint Lazaro gates, by which the sewage of the city, its waste waters and the waters of the valley are conducted to the tunnel, thence to a river emptying into the Gulf of Mexico.

The «Graveholz,» on the Bergen Railway in Norway, about three and one-third miles in length, and the Yanagase Zama forming a part of the Tsuruga-Nagahama Railway in Japan.

Two London river tunnels deserve mention. The Blackwell tunnel under the Thames is a mile and a quarter in length, but only 3,088 feet are under the river, 1,370 feet are roofed over and the remainder of the length is composed of the open-cut entrances. It was driven with a 28-foot shield and built of great cast-iron rings steadied with cement. The Rotherhithe under the Thames is about the same size.

New York River Tunnels.— This article would not be complete without reference to the great under-water tunnels constructed around Manhattan Island during the opening years of the century. The greater part of New York city lies on Manhattan Island and to afford easier railway communication from all sides a series of very difficult under-river tubes was planned and built. The four largest were built by the Pennsylvania Railroad Company, to bring its traffic into New York from Jersey City and to carry it over the East River to Long Island. The Hudson and Manhattan Railroad system built four under the Hudson for passenger communication between New Jersey and New York, affording an outlet for the passengers of the Lackawanna and Erie railways and also for Pennsylvania passengers from Newark and local points. The pair of Belmont tunnels was constructed to connect Long Island City with New York and open up Queens County to development. The Rapid Transit tunnels run from the Battery in Manhattan to Joralemon street, Brooklyn. Two other pairs of tunnels are under construction to join Manhattan and Brooklyn. No other great city was ever so thoroughly honeycombed by tunnels. See NEW YORK CITY; TUNNELS, RIVER AND LAKE.

Bibliography.— For further detailed information consult Drinker, 'Tunneling' (New York 1874); Legoux, 'De l'emploi du bouclier dans la Construction des souterraines' (Paris 1897); La Dame, 'Les grands tunnels des Alpes et du Jura' (Paris 1889); Danino, 'Gallerie della traversata dell' Appenino, nella linea Foglio' (Rome and Naples 1875); Prelini, 'Tunneling' (New York 1901); Simms, 'Practical Tunneling' (New York 1896); also the following works describing tunnels: Von Rosenburg, 'The Vorburg Tunnel' (New York 1887); Walker, 'The Severn Tunnel' (London 1888); Burr, 'Tunneling Under the Hudson River' (New York 1885); Sutro, 'The Sutro Tunnel' (New York 1887); Cochrane, 'Modern Industrial Progress' (Philadelphia. 1905); Stauffer, D. M., 'Modern Tunnel Practice' (New York 1911); Brunton and Davis, 'Modern Tunneling' (1914). See SUBWAYS; TUNNELS AND TUNNELING.

TUNNELS, River and Lake. Hudson-Manhattan Tunnels.— These are frequently termed the McAdoo tunnels. They consist of two separate sections of sub-aqueous tubes: (1) The twin tubes which run from the Hoboken, N. J., terminus of the Delaware, Lackawanna and Western Railroad crossing the Hudson River to below Christopher street, New York City, and running to 6th avenue, thence uptown to 32d street. (2) A pair of tunnels driven from the terminal of the Pennsylvania Railroad in Jersey City across the Hudson, entering New York City at Cortland street.

Haskins Tunnel.— The early history of the up-town twin-tunnels under the Hudson River is a tragic one. D. C. Haskins, a westerner of wealth, conceived the idea that the Hudson River could be crossed by a tunnel formed by boring in the bed of silt deep below the surface, maintaining an air pressure in the heading equal to the hydrostatic head outside and retaining the excavated space by insertion of a series of iron rings as fast as the boring progressed. Work was commenced in 1874 from the New Jersey side; it was the first attempt to tunnel the Hudson River. A shaft was sunk to 54 feet below mean high water, an air lock was built and the regular tunneling began with an air pressure of about 18 pounds at the shaft, increasing to 36 pounds at 1,600 feet distance. After carrying this north heading a quarter of a mile, the south tunnel was started. Then the New York end was commenced with sinking a timber caisson to a depth of 56 feet below high water. Blow-outs occurred with flooding and letting in of silt, which ended in a serious blow-out in 1880, cutting off the escape of the

excavating crew and drowning 20, thereby ending operations. In 1888 S. Pearson and Son of England took up the contract, and the shield method of driving was used, but financial troubles closed out operations till 1902, when the plant and franchise were acquired by the New York and New Jersey Railroad Company, who renewed the effort. In 1905 the Hudson Company obtained the tunnel interests and the operation became part of what is known as the McAdoo System.

McAdoo Tunnels.— With the amalgamation of the New Jersey Railroad Company and the Hudson-Manhattan Railroad Company in 1903, the McAdoo System started in operation. Leaving out consideration of the great terminal and other works, the great tunneling feat alone is featured here. The overcoming of the many very difficult engineering problems was placed under the management of Charles M. Jacobs and J. Vipond Davies, and they determined on the employment of compressed air as a medium for operating drills, shields and all mechanism used in construction. On the Jersey City side the former shield service was used with certain necessary changes, such as heavy hood or apron to protect the workers. Pressure of 33 pounds was carried, as the upper stratum of the tunnel was of silt. Blow-outs were closed with clay blankets supplied from scows waiting in readiness. The shield was driven by hydraulic jacks with 2,500 tons aggregate thrust to make passage through the silt, thus making excavation unnecessary. A rock reef at one time was struck that reached 16 feet above the bottom of the space to be tunneled, the upper part being of clay so fluid as to slip into the pockets of the shield. Gigantic blow-pipes supplied with fuel from tanks of kerosene were used to bake the clay to sufficient hardness as to permit the excavators to work on the rock beneath. The tunnel diameter of 15 feet 3 inches was lined with cast-iron plates bolted together in circular section. The greatest engineering feat in this great undertaking was the construction of the tunnels at the junction of the Christopher street, 9th street and 6th avenue, New York City. At this point two tunnels run east under 9th street and two north under 6th avenue. Overhead here were the surface car lines of the Metropolitan Street Railway, and above this the Elevated railroad, both in operation. An arch, to accommodate two tubes approaching from the south and four tubes diverging east and north had to be constructed with 68 feet maximum width, and the soil was a "running sand." The enormous difficulty was overcome by constructing two iron-lined temporary tunnels and the side walls being built in. Then, through openings on top of the tunnels, heavy false work was constructed strong enough to permit springing the arch. The temporary tunnels were then eliminated. Any accidental disturbance of the timbering meant that the surface lines and Elevated structure must fall into the excavation. Tunnels from Jersey City to Morton street, New York City, started 1874, opened for traffic 1908, consisting of two single-track tubes 5,000 feet long with minimum diameter 15 feet 3 inches. The two down tunnels connecting Jersey City with Cortland, Church and Fulton streets, New York City, were commenced in 1905 and opened for traffic operation in 1909. These consist of two tubes 5,950 feet long and 15 feet 3 inches inside diameter. As to the land sections of the Hudson-Manhattan tunnels, one connects, by two single-track tubes, the Hoboken terminal with the Jersey City Pennsylvania Railroad station, running parallel with the Hudson River. This was completed in 1911. Another land subway connection runs from Morton and Christopher streets to connect with 33d street, running along 6th avenue. This was opened to the public in 1910 and was constructed with shield to 12th street, then cut-and-cover to 33d street.

Cleveland Water Works Tunnels.— This tunnel is under Lake Erie and is a three-mile sub-aqueous tunnel driven by hydrualic shield and lined with concrete blocks. The character of the soft ground permitted a speed of 886 feet in one heading. The soil met with was stiff clay, free from runs. But accumulations of marsh-gas made hazards of explosions equal to those in coal-mining, and necessitated coal-mine methods of precaution. The land heading carried the longest continuous compressed-air section recorded — 14,000 feet finally. Irregularities in advancing the shield (due to inadequate survey force) took the workers 180 feet out of alignment and out of grade line 6 feet above and below. When the two headings were approaching to about 1,500 feet of each other an expert survey was made and a "reverse curve" course was made to get the junction. The tunnel diameter is 10 feet inside, its length 16,088 feet and it runs 100 to 110 feet below the level of the lake with a gradient of about 10 feet. There is a roof crust of 50 to 70 feet between tunnel and lake bottom. The clay, though stiff, did not permit working without air pressure and 20 pounds was the average carried. The shield used was a simple riveted-steel double ring structure free from interior partitions and diaphragm. It was furnished with a cast steel cutting edge of usual type and was without hood. Its length in all was 15 feet 1 inch with diameter 12 feet 2⅛ inches. A dozen jacks with 9-inch plungers drove it forward using 1,500 to 3,000 pounds pressure per square inch. The work started with excavation by means of a rotary cutting machine, which was, however, discarded in favor of hand work for half the tunnel because of changed character of the soil. The chief innovation in this tunnel is the block lining substituting bricks used in other Cleveland intake tunnels. The blocks used were the Parmley variety of patent concrete for the first 2,500 feet of land-heading, then a block designed by the city's own engineers. The latter did away with the cast-iron segments customary, thereby reducing cost. The lining is 11½ inches thick. The headings met in December 1916.

Astoria Gas Tunnel.— This New York tunnel is 4,262 feet long. It extends from the Astoria plant of the Astoria Heat, Light and Power Company, opposite Hell Gate to the 132d street distributing station in the Bronx. It is run at a depth of 225 feet. The Astoria shaft is 34 feet 6 inches in diameter, 279 feet 9 inches deep, while the Bronx shaft has 26 feet diameter and is 233 feet deep. The total length of tunnel with shafts is 5,171.79 feet. It has a D-shaped cross section with bottom slightly

concaved; the excavated section was 19 feet 9 inches wide and 21 feet high. Shafts and tunneling are lined with concrete from 18 inches to 36 inches thick. The lining in the tunnel is reinforced with steel rods where bad ground is met. Inside cross section of completed tunnel is 16 feet 9 inches wide and 18 feet high. The stratification met with was Fordham gneiss at terminals and Inwood dolomite between. Ground was broken 12 Sept. 1910, and tunnel was finished in 1914. It carries two 72-inch gas mains and is provided for two more. In removing the remaining 122-foot bench to finish the excavating, in July 1913, a great rush of water was struck. The serious difficulty was overcome by covering the entire west side of the exposed bench by a series of concrete bulkheads and buttresses. But a rush of water near an emergency bulkhead that had been erected flooded the tunnel. Grouting till 8,850 bags of cement had been injected at a pressure of 400 per square inch sealed the leak, when the tunnel was pumped out after a delay of 102 days.

Detroit River Tunnel.— This tunnel was projected to carry the main line of the Michigan Central Railroad under the Detroit River across to Winsor, Can. Its sub-aqueous section is a twin tube 2,625 feet in length extending from a shaft back of the dock line on the Canadian side to one similarly situated on the Detroit shore. The Detroit side approach is a double track parallel to the main lines for 1,540 feet to the portal of a twin-arch approach tunnel 2,135 feet in length. This latter has a 2 per cent grade under yards and tracks. The Canadian approach contains 2,900 feet of open cut and 3,600 feet of twin-arch tunnel all on 1.5 per cent grade. The two sub-aqueous tubes are circular with a diameter of 20 feet. They have a continuous ⅜-inch steel plate shell 23 feet 4 inches in diameter enclosing a lining of 1:2:4 concrete, 20 inches thick. This concrete is reinforced by 1-inch longitudinal rods 18 inches apart on centres in a concentric circle. A concrete mass 1:3:6, 55 feet 8 inches wide at top and 30 feet 10 inches deep surrounds the tubes. This produces a continuous monolithic tunnel of two tubes having a diameter of 20 feet. The method of construction consisted of dredging a trench in the river's clay bed. The twin steel shells, which were constructed on the shore in 11 bulkheaded sections were floated to position and sunk separately, then connected by special joints. The concrete coating was deposited through tremies from a scow filling a form surrounding the shell sections. The water was next pumped out from each section and the 20-inch concrete lining was placed while other sections were being sunk. This process eliminated working in compressed air and has given much satisfaction. The sections of tubes are reinforced every 12 feet by vertical transverse diaphragms of ⅜-inch plates, stiffened at the diagonals and outer edges with 3½ by 3½-inch flange angles. Each section of the tubes received a 5-foot deep temporary bulkhead at each end before floating, affording a 10-foot space between the sunken sections and a manhole admitted a diver from the outside. The twin-tube sections were constructed on ways at the Great Lakes Engineering Company's shipyard 40 miles from their destination. They weighed about 550 tons and had a length of 262.5 feet. One section for closing was 64.5 feet long and weighed about 130 tons. The sections were towed by tugs from shipyard to tunnel site, requiring about 12 hours each. The trench in the river had a 48-foot bottom and a depth of from 22 to 40 feet. The first tube section was sunk 3 Oct. 1907, and the last during the fall of 1909.

Catskill Aqueduct.— This is a tunnel construction for supplying New York City with water conveyed from the Catskill Mountains. It is claimed by many experts as the most stupendous engineering project ever completed, even including the Panama Canal. It carries the water from the mountains to Staten Island a distance of 120 miles, and adds a capacity of 375,000,000 gallons per day to the New York City supply, and reserves a supply sufficient for a series of years of drought. The tunnel taps the great artificial Ashokan Lake which is fed by the Esopus Creek. It extends 92 miles from the reservoir to the northern boundary of New York City and continues 35 miles within the city limits, including the branch to the borough of Queens, Kensico storage reservoir, Staten Island, etc. The water supply is on a gravity system, free from pumping. The conduit of which the aqueduct consists is made up of several types, plain Portland cement concrete constructed in trenches then covered with earth; grade tunneling, pressure tunnels and steel-pipe syphons. Of the first is 55 miles construction having horseshoe section 17 feet high by 17 feet wide inside, composed of concrete without steel reinforcement and covered with earth embankment. Being the least expensive type this was used as much as the conditions permitted. Of grade tunnels there are 24 (14 miles in all) horseshoe shape, 17 feet high, 13 feet 4 inches wide. To cross broad, deep valleys circular tunnels were driven in the rock (where suitable) and lined with concrete. There are seven pressure tunnels of a total of 17 miles and a diameter of 14 feet. The connection of the pressure tunnels with the adjacent aqueduct portions is made (with one exception) by shafts. This exception is the Bryn Mawr steel-pipe siphon and Yonkers pressure tunnel. The tunnel through the city is also a pressure tunnel 18 miles long. For cleaning, repairs, etc., drainage shafts are furnished each pressure tunnel to unwater the same. The Hudson River is crossed in a tunnel excavated through granite 1,114 feet below sea-level connecting with a shaft at Storm King Mountain on the west bank and another shaft at Breakneck Mountain on the eastern bank of the river. Where the rock is insufficiently sound in valleys steel-pipe syphons were used instead of pressure tunnels. The pipes were constructed of 7 1-16-inch to ¾-inch steel plates rivetted together. The inside is lined with two inches of cement-mortar, and the tunnel is enveloped with concrete and covered with an earth embankment. There are 14 of the siphons with an aggregation of six miles. The cost of the Catskill water supply system, when completed, including surveys, real-estate, construction, engineering, general supervision and all items except interest on bonds will be $177,000,000, which will include the Schoharie addition.

New York Rapid Transit Tunnels.— The East River tunnels consist of four twin-tube tunnels, as follows:

1. *Old Slip Tunnel.*— From Manhattan to

Clark street, Brooklyn. This creates the Brooklyn connection for the "Seventh Avenue-Broadway" or west side line of the Interborough Rapid Transit Company's system. The bore between shafts is 3,799 feet long, with the land tunnel on the Manhattan side 355 feet long and that on the Brooklyn side 1,750 feet long. These tubes afford a single track totaling 11,800 linear feet. On the Manhattan side the tunnels passed through a section 975 feet long consisting of mica-schist in bottom and sand in the top of the tunnel. Under the centre of the river they passed through gneiss for a length of 470 feet. The rest of the tunneling was through soft material, mostly sand and fine gravel, with bowlders on the Brooklyn side. At the lowest point the tops of tubes are 71 feet below mean high water. But in places the natural cover over the tubes is *nil*. Here the former experiences with clay blanketing proved invaluable. Clay was dumped from the river surface to provide the necessary cover. Clay blanket process was used elsewhere to prevent "blow-outs." The lining consisted of standard bolted cast-iron rings 26 inches wide. Outside diameter of tunnel is 17 feet 6 inches. In rock inside diameter of iron is 16 feet 4 inches and a net clear diameter after concrete lining of 15 feet 4 inches. In soft ground heavier iron is used, giving 16 feet inside diameter of iron, and the net clear diameter of tunnel is 15 feet. In *rock*, the clear space outside the iron lining was packed with stone and grouted with Portland cement. In *soft ground*, fine gravel and grout were forced out by compressed air to fill the void left by the passage of the shield. The shield was worked in compressed air under a maximum pressure of 37½ pounds. Work commenced January 1915, and tunnels were opened to traffic April 1919. Cost was $6,300,000, including the station in Clark street, Brooklyn. The chief difficulty encountered was in tunneling almost directly under the foundations of buildings in Clark street, Brooklyn, in loose sand and gravel. This was successfully overcome by careful breasting of the face, and by blowing gravel and cement grout under high pressure to fill the voids behind the tail of the shield. This stopped all "settling," henceforth, of contiguous buildings.

2. *Whitehall Street, Manhattan, to Montague Street, Brooklyn.*—This tunnel will connect the Brooklyn Rapid Transit system on 4th avenue, Brooklyn, with the lower Broadway (Manhattan) line of the same company, now in operation. The length of this tunnel between shafts is 4,290 feet, the land tunnel, Brooklyn side, being 1,700 feet long. There are two "spurs" running into these tubes from the foot of Broad street, Manhattan (700 feet long), to provide for a future subway in that street. This tunnel affords a total single track of 13,735 linear feet. The tunneling was driven in mica-schist on the Manhattan side to a point 1,750 feet from the Manhattan shaft. The rest of the tunneling was in sand and gravel except for a reef of gneiss in the centre of the river, about 400 feet long. At the lowest point the tops of tubes are 75 feet below mean high water. Natural "cover" in the river in soft ground ran from 6 to 25 feet, but a clay blanket was used, when the tunnel was in soft ground, as a precautionary measure throughout. Standard bolted cast-iron, 26 inches wide, rings were used as lining. Outside diameter of iron was 17 feet 2 inches and 18 feet. The latter was always used when a shield was employed. Inside diameter of iron was 18 inches less in earth and 14 inches less in rock. Clear diameter after placing concrete lining is in all cases one foot less than inside diameter of iron lining. Outside the iron lining the same system of packing voids was used as in the Old Slip tunnel (see above). The excavation was carried forward by the medium of shield and compressed air; maximum pressure was 34½ pounds. Work commenced October 1914, and is nearly complete. Estimated cost is $5,750,000. In the course of the work the same difficulties were encountered as in the case of the Old Slip tunnel.

3. *Sixtieth Street, Manhattan, Tunnel to Borough of Queens.*—This tunnel will connect the Interborough Rapid Transit Company's elevated system in Queens, over which the Brooklyn Rapid Transit Company has operating rights, with the Brooklyn Rapid Transit subway under lower Broadway (Manhattan), now in operation. Length of tunnel from 2d avenue, Manhattan shaft is 1,364 feet. From Manhattan shaft to Blackwell's Island shaft is 1,610 feet, and from Blackwell's Island shaft to Long Island City portal is 1,740 feet. The Long Island City approach is in cut-and-cover and elevated construction and 2,607 feet in length. This twin tunnel affords 14,642 linear feet of single track. The tubes run through 1,800 feet of mica-schist from 2d avenue to the edge of the river on the Manhattan side, then through 700 feet of sand under the west channel of the East River, then through 1,200 feet of gneiss under Blackwell's Island, then through 600 feet of soft ground under the east channel of the East River, then through 400 feet of gneiss to the portal in Long Island City. At the lowest point (which occurs in the west channel) the tops of tubes are 98 feet below mean high water. At this point the tubes emerge from the natural river bottom, and tunneling had to be carried out through an artificial clay blanket 45 feet thick. Standard heavy. cast-iron lining was used only where shield was used, i.e., in soft ground or unsound rock. The iron rings are of the same type as in the above-described Whitehall street tunnel. In sound rock a circular concrete lining 13 inches thick was used, leaving a net maximum clear diameter of 15 feet. Where light iron lining was used (in unsound rock), the clear space outside was packed with stone and grouted with Portland cement (as in former cases). In soft ground only enough grout was used to fill the space left at the sides of the tunnel to prevent flattening; no structural weight being overhead in soft ground portions, filling or grouting was unnecessary. The maximum pressure used in shield work was 48 pounds. Work commenced August 1916 and was completed June 1919, but is not yet open to traffic; the cost was $4,230,000. The chief difficulty was the very high air pressure. This involved, at one time, 16 shifts daily. The men worked two 45-minute periods in the high pressure with a 5-hour interval.

4. *East Fourteenth Street, Manhattan, to North Seventh Street, Williamsburg.*—This tunnel connects the Brooklyn Rapid Transit Company's lines in Williamsburg (Brooklyn)

and East New York with a subway extending west under 14th street to 6th avenue, Manhattan, with provisions for transfer of passengers to the Brooklyn Rapid Transit subway on lower Broadway, now in operation. Its length between shafts is 3,437 feet. The Manhattan land tunnel is 1,627 feet, and that on the Brooklyn side is 2,025 feet. These twin tubes afford a single track 14,178 linear feet long. The land headings are entirely in soft ground, and the shield method with compressed air was used. The river tunnel proper (between shafts) will be in rock for about 2,300 feet and in sand and gravel for the rest of the distance —about 1,140 feet. At the lowest point the tops of the tubes are 97 feet below mean high water. The cover is ample except under the main ship channel near the Brooklyn side, where the tops of the tunnels emerge from the natural river bed, and there a clay blanket is used. The type of lining is same as described for Whitehall street tunnel (see above). About 1,100 feet of tube in sound rock will have no iron lining, but will be lined with a circular concrete lining 13 inches thick. Minimum clear inside diameter will be 15 feet. Filling of voids will be done on the same process as described in the case of Old Slip tunnel. Excavation is by shield in compressed air in soft ground; in rock without compressed air. Maximum pressure employed was 39 pounds. Work commenced August 1916 and is not completed. Land headings and soft ground shield excavation are complete from both shafts, and the headings in rock near the middle of the river were joined August 1919. Cost will be about $6,000,000. No unusual difficulties have been encountered.*

Harlem River Tunnels.— These connect the Lexington avenue subway with its extension northward into the Bronx. Its construction was carried out in substantially the same system as the Detroit River, Michigan Central tunnel described above. It consists of constructing steel tube sections; floating them to site; sinking into excavated river-bed trench; adding concrete outer covering through tremies. The metal sections are next unwatered and inner concrete lining added. This system eliminates working in compressed air, except in the few cases where divers' work is needed. This tunnel consists of four tubes rigidly fastened together by diaphragms. It was sunk in five sections, four of these sections being 220 feet long each and one 200 feet, or a total length of 1,080 feet. The diaphragms were spaced 15 feet and 7 inches apart and formed convenient pockets for placing the surrounding concrete. In the matter of joints a butt joint was used instead of the overlapping joints used in the Detroit work. Stiffening angles, which were used in the Detroit tunnels, were here placed outside. This saved much timber. This was a much easier engineering work than the Detroit tunnels, the distance being but 600 feet between the river bulkheads, and the top of the tunnel is only 7 feet lower than the original river bed. The Harlem River tunnels are 16 feet 6 inches in diameter inside the concrete lining, the interior walls having flat sides. The width of the finished structure is 76 feet and the height 24 feet 6 inches, including the surrounding concrete. The last section of tubing was sunk in September 1914.

The engineering of the New York subway tunnels was carried out under the direction of the Public Service Commission for the First District, State of New York. Mr. Alfred Craven was Chief Engineer during the inception of these projects and is still active as consulting engineer. Mr. D. L. Turner became Chief Engineer April 1917. Mr. Clifford M. Holland was in direct charge of the work as engineer of the tunnel division. For bibliography see under TUNNELS, GREAT MODERN.

TUNNELS AND TUNNELING. A tunnel may be considered an underground or sub-surface passage of any form of cross-section most suitable for the purpose of construction or for the purposes to be served after construction. It is ordinarily supposed to be constructed without disturbing the natural material over it or around it, although in some modern engineering works true tunnels are constructed by first removing the overlying material by open excavation if on land, or by dredging if under water, then constructing the tunnels by suitable means and refilling over the completed structure. Tunnels are of all sizes as well as shapes of cross-section and may be horizontal or inclined; indeed, a shaft may be considered a vertical tunnel. When tunnels are small and built ahead of the main structure or for subordinate purposes, as in mining, they are called headings or adits. Obviously, tunnels may be constructed for a great variety of purposes. They are commonly employed for railroad purposes, for the passage of foot and vehicular traffic under rivers as in the city of Chicago, for sub-surface transit purposes in large cities as in the city of London, to form aqueducts in great water supply systems, as for the city of New York with the 31-mile Croton aqueduct tunnel, for sewer purposes, and for serving other public conveniences in modern communities.

Ancient History.— The art of tunnel building is one of the oldest of engineering procedures. The ancient Egyptians built extensive tunnels for tombs and temples, and nearly or quite the same thing was done in ancient India. The ancient Assyrians constructed a tunnel under the Euphrates River, after having diverted its waters to another channel, the cross-section of which was 12 feet wide by 15 feet high. They also built other tunnels. The ancient tunnels were probably invariably built in rock or other hard material in which there was not sufficient water to give material trouble; there is no record of a true sub-aqueous tunnel being built in ancient times. Methods adapted to tunnel excavations through soft material saturated with water have been developed only in comparatively recent times. The old Romans were by far the greatest engineers of ancient times and they excelled all earlier peoples in their tunnel constructions as they did in all other constructions. The "fire-setting" method of tunneling was due to them as was also the method of sinking vertical shafts at different points on a tunnel line to afford a greater number of points of attack

* Above stated costs are for finished structure without track and equipment except ducts on either side, embedded in concrete benches both sides of tubes, to carry electric cables,

on the work. They built fires in their tunnels against the rock to be excavated, and, after heating it to the highest practicable temperature, suddenly chilled it by pouring water on it and taking advantage of the resulting softening, cracking and disintegration. They were also aware of the advantage of using vinegar instead of water in this method of tunneling through calcareous rocks, thus taking advantage of chemical action as well as disintegration by alternate heating and chilling. Probably the longest of the old Roman tunnels was that built to drain Lake Fucino; it was designed to have a section 6 feet by 10 feet. Forty shafts as well as inclined galleries were sunk for the construction of this tunnel 3½ miles long. The deepest shaft was about 400 feet. Most of the Roman tunnels were small, but they occasionally built large ones, like that for the highway in the Posilipo Hills between Naples and Pozzuoli, 3,000 feet long and 25 feet wide at the centre. The entrances are 75 feet wide and at the centre the height is 22 feet. Its general form, therefore, approximates the frustra of two cones with their small bases joined. This was for the purpose of concentrating the light in the central or less illumined portion.

In the Middle Ages.— Obviously the construction of ancient tunnels was excessively slow as well as laborious, although drills, chisels and even saws, fitted with hard cutting stones like corundum for teeth, were used even by the early Egyptians. Hammers and wedges were also employed. The first application of gunpowder of importance was probably at Malpas, France, in 1679–81, in the construction of the tunnel on the line of the Languedoc Canal, 510 feet long, 22 feet wide and 29 feet high. The first stimulating demand for modern tunnel construction of any great amount began with the construction of canals in France and England during the last half of the 17th century, and all of those tunnels were either in rock or dry hard ground. It was not until after 1800 that tunneling through sand and wet ground was undertaken in sufficient magnitude to be regarded as a branch of engineering construction. A tunnel for the Saint Quentin Canal in France was built through soft soil in 1803. The width of this tunnel was 24 feet, and timbering including struts and planking was used to support the walls and sides prior to constructing the masonry lining. From the earliest times the necessity of lining tunnels with masonry was recognized and it was done wherever the material was of such a weak and uncertain character as to make its self-sustaining qualities doubtful.

Modern Tunnels.— The greatest stimulus of all to the construction of tunnels was given when the construction of railroads began. From that time until the present, tunnel works of great magnitude, including those through sub-aqueous material, have been constantly constructed. Among the earliest of these were two tunnels built on the line of the Liverpool and Manchester Railway in England. The first tunnel of any kind built in the United States was that known as the Auburn Tunnel near Auburn, Pa., built in 1818–21 by the Schuylkill Navigation Company for the water transportation of coal. This tunnel was several hundred feet long and was about 22 feet high by about 15 feet wide. The first railroad tunnel in the United States was also in Pennsylvania on the Allegheny Portage Railroad and was built 1831–33. It was 901 feet long, 25 feet wide and 21 feet high. What may be properly termed epoch-making tunnel structures in the United States and in Europe are the Hoosac Tunnel in Massachusetts and the Mont Cenis Tunnel which pierces the Alps between Piedmont and Savoy. These are termed epoch-making structures because the exigencies of their construction first brought into use power-drills and high explosives, the two great modern agents in rapid and economical rock tunnel construction. The Hoosac Tunnel was built between 1854 and 1876, the progress of the work having been interrupted over long periods. Its total length is about 4¼ miles and it is a double-track tunnel. The Mont Cenis Tunnel was built between 1857 and 1872 and has a length of 7.6 miles. This is a single-track tunnel. The beginning of the work on the Hoosac Tunnel was quickly followed by the commencement of the double-track Erie Tunnel through Bergen Hill, near Hoboken, N. J. This tunnel was built 1855–61 and has a length of nearly 4,400 feet. Its greatest height is 21 feet and its width 28 feet. Among the more prominent tunnels of this country driven through rock, there may be mentioned the Croton Aqueduct Tunnel, 31 miles long with a horseshoe cross-section in general 13.53 feet high and 13.6 feet wide. The Niagara Falls Power Tunnel, 6,700 feet long, has a horseshoe section 19 feet by 21 feet. The single-track Cascade Tunnel on the Northern Pacific Railway, built in 1886–88, is 9,850 feet long. It is 16.5 feet wide and 22 feet high and is lined with masonry.

General Methods of Operation.—The more simple methods of excavating tunnels may evidently be employed for rock and firm earth or other materials relatively dry. In such cases it is customary to divide the cross-section of the tunnel into a number of parts and excavate them in such order as will be most conducive to economy and speed of completion. This division of the section into those parts successively excavated is illustrated by Figs. 1, 2 and 3. In each of those figures the numbers show the order of excavating the different portions, the part 1 being the first removed in each case. Fig. 1 shows the sequence of removal followed

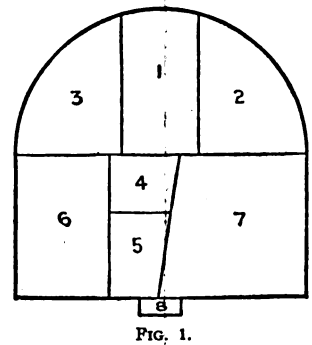


FIG. 1.

in the Saint Gotthard Tunnel, while Fig. 2 exhibits that followed in the Mont Cenis Tunnel; Fig. 3 illustrates the order of excavation in the "German method" of tunneling. If the first part, numbered 1 in the figures, is in the top

of the tunnel it is called a heading, but if it is at the bottom of the section it is called a drift. The heading or drift being first driven, the full tunnel section is reached by enlargement in the order or sequence shown. The usual width of heading is about 8 feet, although it may be but 6 feet. The height is about 7 feet. These dimensions give room for two men to work. Driving the heading is the most difficult and expensive operation of the tunnel excavation. These headings are sometimes driven 1,000 to 2,000 feet ahead of the full section, although that is not common. The alignment of the heading, which is also the alignment of the completed tunnel section, is transferred with great accuracy from the surface, either at the ends of the tunnel or down through shafts by various and well-known methods of engineering surveying. Shafts are the vertical passages sunk from the surface along the centre line of the tunnel or at a

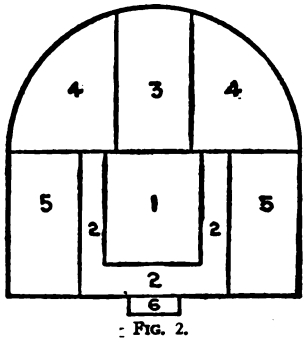

FIG. 2.

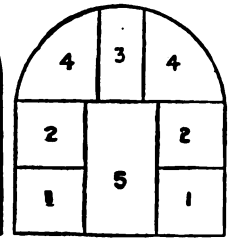

FIG. 3.

short distance on one side of that centre line for the purpose of attacking the excavation at as great a number of points as possible. They enable the work to be extended both ways from the point where the shaft is sunk and also form points at which the excavated materials are raised from the tunnel; they also permit material for lining or other purposes to be lowered into the excavation and put in place. Central shafts are usually employed, although French engineers frequently adopt side shafts having their axes 30 to 40 feet on one side of the centre line of the tunnel. At the present time power elevators are used in shafts for raising and lowering men and material. When the shafts are left open and lined where necessary, they become permanent features of the completed structures, affording ventilation. Where shafts are filled after the work is completed they are called temporary shafts, and they may be circular in section as is usually the case where they are lined, or they may be rectangular, their sides being braced with timber to prevent material falling in. Central shafts are more convenient than side shafts. If water flows into the tunnel excavation or is found in shaft sinking, it must usually be pumped to the surface. Tunnels are usually classified in relation to the material in which they are driven, such as tunnels in hard rock, in loose soil, in quicksand, cut-and-cover tunnels, sub-aqueous tunnels. On the whole, hard rock is probably the safest material in which to drive a tunnel and it gives the least difficulty. This is true chiefly in view of the effective explosives and covenient power-drills and other machinery now available for the purposes of excavation. Rock tunnels may be driven by using either a heading or a drift, depending upon the local circumstances in choosing the method. Tunnels in soil may involve serious difficulties if the soil is saturated with water. The excavation may be first made near the top, that is, near the soffit (the Belgian method); or along the perimeter (German method); or in two halves entirely independent of each other (the Italian method); or, finally, the whole section together (the English and Austrian methods). The Belgian method is more frequently employed in Europe. After excavating the material under the soffit the arched roof of the tunnel is constructed and supported on either side of the excavation until the lower part of the material is removed, when the necessary side and bottom lining is completed. In the German method two drifts are driven, one on either side of the lower portion of the section, as shown in Fig. 3, then others are

2 Harlem River Tunnel (Lexington Avenue Line). Section of tubes being towed into position for sinking — showing the four temporary buoyancy cylinders

opened above them until the completed perimeter except the lower central portion, which is then termed the "bench" (see Fig. 7), has been exposed. The masonry lining is then completed above the bottom. After removing the central portion of the material the invert or bottom of the masonry lining is put in place. The Italian method is more expensive than the others and is not often followed, but the English method is employed by excavating lengths from 10 to 25 feet, the masonry invert lining being completed first, then the side walls, and the top arch last. Tunnels in quicksand must be driven by methods applicable to soft soil saturated with water. Cut-and-cover tunnels have been more used for subways in cities than for other purposes. The most notable cases of these latter tunnels are the recently completed subways in the city of New York and the Boston subway, although a considerable portion of the latter was built without removing the material over the top of the finished arch. Sub-aqueous tunnels are the most difficult of all to build and require the employment of special methods and appliances which will be described later on.

Excavation.— The statement on the preceding page shows the general character of excavation for thetion for the different kinds of tunnels to which allusion has been made. It is taken from 'Tunneling' by Charles Prelini, C. E.

The Timbering of Tunnels.— As excavations are made for tunnels not only in rock, but also frequently in soft material, it is necessary to support the sides and top of the excavation to prevent material falling in, and this support is usually given by timber struts and planking, called either lagging or poling boards, suitably disposed concurrently with the excavation. As round sticks are more economical than sawed timber they are usually employed for this purpose. Methods of putting this timber in place vary largely with the methods of excavation employed and the sequence in which various portions of the tunnel are excavated. If the material is reasonably self-sustaining, as clay and much firm earth as well as most rock, the entire excavation may be completed closely in front of the timbering already in place if it is not desired to follow the excavation immediately with the masonry lining. In rock tunneling the masonry lining may usually be completed, where needed, immediately following the excavation without much or any timbering. In soft material, however, it is usually necessary to use timber supports, even for the first excavation, in the heading or drift. In fact, it is commonly necessary to insert poling boards, as they are called, ahead of the actual excavation, as shown in Figs. 4 and 5. The poling boards are inserted over the crown bar or top horizontal round stick of the bracing and under the block on which one end of the previous poling board rests, thus enabling the soft material to be excavated at the front part of the heading without the newly exposed material falling down. After the heading or drift is thus excavated and timbered. other portions of the cross-section are excavated concurrently with placing the supporting timbers, so that when the entire section is excavated there will be a complete system of supporting struts and cross timbers with the poling boards or lagging resting directly against the soft material of the sides and roof. These supporting timbers are so placed as to permit small dump or tram cars to be used for carrying out the excavated material. Obviously, the precise method of using poling boards will depend upon the manner or sequence in which the different portions of the excavation are completed and the kind of material found. It is equally evident that the poling boards and lagging may be used lengthwise of the tunnel or transversely, as shown in Figs. 4 and 5, the former necessitating the excavation of the least amount of material and being preferable in most cases. After thus completing the excavation and timbering, the masonry lining may be put in place, the timbering being removed as fast as the masonry progresses. The lagging and poling boards usually remain undisturbed back of the masonry lining. The timber which has been removed when the masonry is laid may be repeatedly used, not more than about 20 per cent of it usually being destroyed in any one use.

The Lining of Tunnels.— Reference has already been made to the masonry lining of tunnels. This lining may be constituted of almost any grade of suitable masonry, in accordance with its durability, strength and facility of being put in place. The kind of lining masonry is determined largely by the convenience and economy of the local supply. If the tunnel is in saturated water-bearing material the static head or pressure on the lining may be very great, and the thickness of masonry must be sufficient to carry that water pressure. Occasionally also there may be some little motion of the rock through which the tunnel is driven. In such cases the masonry lining must be of sufficient thickness to resist that movement. While no general rule can be given, the thickness of masonry lining may be from 1 to 4 or 5 feet, the least thickness being suitable for rock not very liable to fall and the greater thickness for such soft material as wet clay and sand and in cases where the static pressure of the saturating water may be very great. In some special locations for temporary purposes timber lining has been used, but it is not ordinarily employed for permanent work. Iron lining has also been employed under certain special conditions, but it is not often used for other than those methods of driving tunnels through soft material with the aid of the pneumatic process and the shield, the circular cast-iron lining being put in place immediately behind the shield. This cast-iron lining is made in sections with flanges for joints and for stiffening purposes which when put in place form a complete circle. These sections are sometimes not more than 2 feet by 4 feet, while in other cases they may be as much as 5 feet or 6 feet square. In all cases they are cast so as to form complete circular cylinders when put in place and bolted together.

The Pilot Method of Tunneling.— This method has not been extensively employed. It was introduced in 1880 by Anderson of Anderson and Barr, who used the method in the construction of the main relief sewer tunnel in Brooklyn, N. Y., in 1891. About 700 linear feet of this sewer has a diameter of 15 feet, 4,700 linear feet has a diameter of 14 feet, and 3,940 linear feet has a diameter of 12 feet, making

9,340 linear feet in all. The material penetrated was mostly sand and gravel, some of it being wet. The principal feature of the method is a wrought-iron cylinder of one-fourth inch plate and 6 feet in diameter, the axis of which corresponds with the axis of the tunnel. This

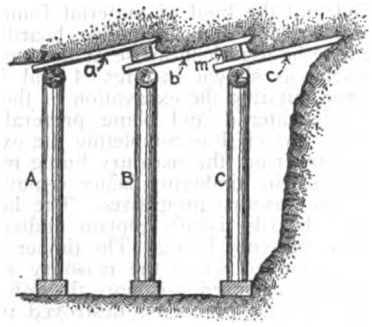

FIG. 4.

small 6-foot heading or pilot is the first portion of the tunnel excavated. The front end of the pilot was carried about 30 feet ahead of the completed tunnel section, allowing a 10-foot length of four-ring brick masonry lining to be put in place, while 15 to 20 feet of the pilot rested in unexcavated material. As fast as excavation was made at the front end of the pilot, plates were taken off the rear end which projected into the finished work and put in place at the front end. In this manner the pilot was carried ahead as fast as excavation could be made. In this case the pilot was built of one-fourth inch iron plates carrying 3-inch by 3-inch angles on their edges. The excavation then made around the outside of the pilot was closely followed by radial struts with one end supported against the pilot and the other end carrying iron plates and lagging to protect the exposed face of the excavation. Iron plates were used over the crown of the finished excavation, but were not carried down on the sides, although they could be so extended if desired. In this manner the complete tunnel was successfully excavated and the material held back until the brick lining used in this case was in place. All work was done at ordinary atmospheric pressure. No other large work has been completed by this method, although it possesses advantages for many localities.

Baltimore Belt Line Tunnel.—This double-track tunnel is a part of the double-track line of railway in the city of Baltimore, Md., built for the Baltimore and Ohio and Western Maryland railroads. It was driven through a great variety of materials, some of which were soft and saturated with water and gave much trouble. Rock was penetrated in some places and in others clay so hard and tough as to require blasting for its removal. For the greater part of its length, however, this tunnel was driven through soft material, some of which carried so much water that it was with difficulty that the work could be prosecuted without danger of serious settlements at the surface above it. In one case the settlement caused the destruction of a large building. The general plan of operations was that of the German method. Drifts along the sides of the tunnel were first driven, thus providing for the drainage of the upper part of the material to be removed. Portions of the side walls were built in these drifts and subsequently extended upward to the elevation of the springing line of the arch. The top heading was then driven and the adjacent side portions were immediately thereafter removed, thus completing the excavation to the full width of the upper half of the section. All these drifts and other excavated portions were heavily timbered and strutted so as to protect the exposed surface to the greatest possible extent. The illustrations show the method of strutting or bracing and the use of the poling boards employed. (Figs. 6 and 7). In laying up the arch of the tunnel both iron and timber centres were employed. As is shown in the illustrations the masonry of the arch and side walls was laid up inside of the exterior line of round struts and the poling boards outside of them. The voids outside of the tunnel masonry were filled with rubble masonry so that no vacant spaces were left unfilled. The lining of the arch in general consisted of five rings of brick work, but where the soil was unusually soft eight rings were employed. The large amount of water in the material under the tunnel caused considerable difficulty in building the invert. Enclosures, however, of short sheet piling transversely across the tunnel were formed, within which the material was excavated and the foundation course of concrete 8 inches thick was laid. On this concrete foundation the brick invert was placed. One of the unique features of this work was the 6-inch perforated pipes which were inserted radially about 10 feet into the soft wet material surrounding the upper part of the tunnel where it was deemed feasible to resort to this procedure. Through these perforated pipes thin Portland cement, mortar or grout was forced into the surrounding soft material, so that when the Portland cement set a solid stiff mass of material was produced instead of the saturated and easily flowing natural material. The bottom side drifts and the masonry walls built in them were ordinarily carried about 20 feet ahead of the arch, although at times this work was as much as 90 feet in advance. The arch was usually built in complete transverse sections about 18 feet in length.

General Features of Method Used in Quicksand.—The construction of the Baltimore Belt Line Tunnel illustrates some of the general features of method suitable for use in quicksands and other soft materials. Quicksands are simply fine sand mixed to some extent with fine clayey matter and saturated usually with running water. All wet material is soft, and in tunneling through such material the first effort is to drain that part of the excavation as effectively as possible. This is accomplished by driving either a centre bottom drift or, as in the Baltimore Belt Line Tunnel, two bottom side drifts, all of which are well calculated to drain the material above them. If the water does not flow away from these drifts by gravity it may be led into sumps and removed from them by pumping. After this draining is accomplished the remaining material is taken out by some method such as those already described, timber bracing or

strutting being introduced concurrently with the excavation. Poling boards are constantly used to keep the material from falling into the excavation and the joints between them are frequently packed with hay or material of similar character so as to permit water to enter without bringing with it the soft material. The masonry lining is then put in place as already described in connection with the Baltimore Belt Line Tunnel, frequently leaving the exterior line of strutting and the poling boards in place. The hardening of soft material may also be produced in other ways than by injecting Portland cement grout, as by freezing or by stock ramming.

Sub-aqueous Tunnels.— All the preceding methods of tunneling described pertain to tunnels not driven below open water, although the material which they penetrate may be fully saturated with water. The most difficult tunneling is that which must be carried on at considerable depths below the surface of free water above the work. In such cases the water finds its way through either porous material or through crevices or fissures in the overlying rock so that both the completed tunnel and the work in progress are subjected to a water pressure represented by the static head of the water above them. Occasionally in rock tunneling under such conditions or in stiff clay, water may flow in upon the work in quantities not too great to make its removal by pumping feasible. Whenever, however, water enters too freely for such procedures, compressed air must be used to keep the water out, the pressure of air being determined by the depth of the work below the water surface. When tunneling is prosecuted under these conditions a «shield» is ordinarily used, as will be described further on. An instance illustrating the method to be followed in sub-aqueous rock tunneling will first be given.

The Severn Tunnel.—This tunnel, a double-track tunnel, a little less than 4½ miles long, was built under the river Severn in the southwestern portion of England between 1873 and

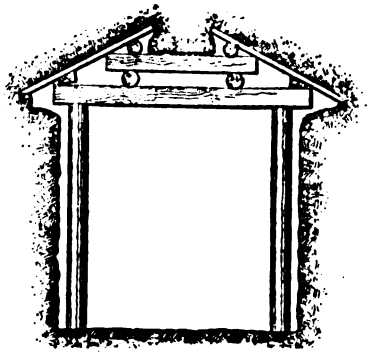

FIG. 5.

1886. Although this tunnel was built largely through rock, for a short distance the material penetrated was gravel. The bed of the river at the tunnel site is composed of strata of conglomerate limestone, carboniferous beds, marl, gravel and sand. The least thickness of the natural cover over the tunnel is 30 feet of marl on the English side of the river. At the deepest part of the river channel the thickness of the sandstone over the tunnel is about 45 feet. The entire tunnel is lined with vitrified brick work 2¼ to 3 feet thick, laid in Portland cement, the invert having a thickness of 1½ to 3 feet. Much water was encountered in the prosecution of this work which produced grave difficulties. Indeed, at one time the entire work was flooded for a period of 13 months. The water gave much trouble at other times, breaking through in large volumes, but in no other instance was the work suspended on account of the water for a period of more than a few weeks. Pumps were employed to raise the water through a side heading connecting with a shaft 29 feet in diameter. The greatest amount of water raised concurrently by all the pumping stations was about 27,000,000 gallons in 24 hours, although the total pumping capacity provided was equivalent to about 66,000,000 gallons in 24 hours. The ventilation of this tunnel, which is a matter of great importance on account of its length, is accomplished by a fan 40 feet in diameter in one of the shafts, making 43 revolutions per minute and drawing out 447,000 cubic feet of air per minute to an 18-foot shaft near to the work.

Tunneling by the Use of a Shield.— The method which has been employed more than any other for sub-aqueous tunneling in soft

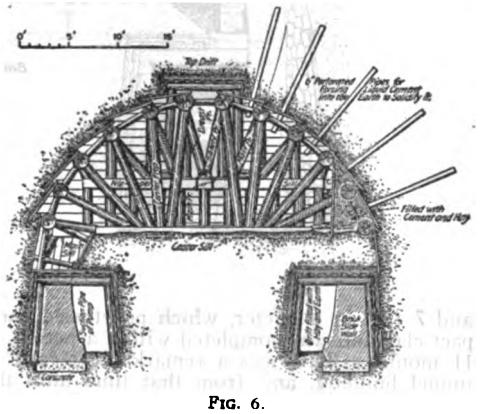

FIG. 6.

materials is that which it is believed was first devised and applied by the great French-English engineer, Sir M. I. Brunel. Brunel was born in France in 1769, spent six years in the United States, then went to England and became one of the greatest civil engineers of Great Britain, where he died in 1849. He secured his first patent covering the use of a shield for sub-aqueous tunneling in 1818. He first employed a shield in the effort to build a tunnel under the Thames River at London in 1823. His first shield was found to be too weak in actual service and had to be replaced by another and somewhat larger one designed by and built under the direction of Brunel himself. This shield was rectangular in transverse section, 37 feet 6 inches wide by 22 feet 3 inches high, and by the use of it two parallel tunnels of horseshoe shape were built, each being 13 feet 9 inches wide and 16 feet 4 inches high, the two being separated from each other by a wall 4 feet thick. This dividing wall was not continuous, but was pierced by arch openings, each about 4-feet span about every 20 feet. The total structure built of brick work was 38 feet wide over all and 22 feet high. The tunnel

was finished in 1843, making the total time of construction, including all stoppages and delays, 20 years. Another English engineer, Peter W. Barlow, patented in England in 1865 a method of sub-aqueous tunneling by the use of a circular shield with a cylinder cast-iron lining for the completed tunnel. After 1869 he was associated with the English engineer, James Henry Greathead (1844–96), in the construction of the tunnel under the Tower of London, 1,350 feet long and 7 feet in diameter, which penetrated compact clay and was completed within a period of 11 months. This was a remarkable record in tunnel building, and from that time until the present numbers of tunnels in soft material under water have been constructed on what is commonly known as the Greathead system, which simply means the use of a cylindrical or circular shield, developed from Brunel's original plan and subsequently perfected by Greathead. The use of the shield has made it possible to construct tunnels under rivers at depths below the surface of the water as great as the effect of compressed air on laborers will permit, it being a matter of comparative indifference how soft the material may be, except that the softer or more easily flowing the material the more carefully must the work be executed. The shield is composed of a cylindrical shell usually constructed at the present time of steel plates and angles or other shapes with a heavy braced diaphragm placed at right angles to the axis of the shell. This diaphragm is of heavy steel plate and shape construction. It may have a number of openings in it closed by doors or other suitable devices. These openings in the diaphragm permit laborers to excavate the material immediately in front of the shield. If the tunnel is a large one the openings may have platforms in front of them, on which laborers stand in order to make the desired excavation through the openings themselves. If the material being penetrated is very soft and porous an inrush of water may take place even when compressed air is used, and the diaphragm must be strong enough to resist the resulting pressure. It may be, and usually is, heavily braced with plates and angles, both vertical and horizontal. The illustrations show how complicated its construction may be. The cylindrical shell in which the diaphragm is located may extend from one to 10 or 12 feet in front of the diaphragm and from 6 or 8 to 26 or 27 feet behind it. The tunnel lining, usually of cast iron from one inch to two inches in thickness and possibly lined with masonry, is constructed within the rear or tail of the cylindrical shell, so that the latter always overlaps by two or three to four or five feet the finished lining of the tunnel, thus preventing any material or water falling into the completed work. Obviously as the workmen excavate the material in front of the shield, pass it through the diaphragm and take it out in the rear, the shield must be moved forward so as to bring its front end again up to the face of the excavation. As these shields are very heavy masses of steel, weighing sometimes 40 to 80 tons or more, and as the friction of the surrounding material on the sides of the shell must be overcome, a heavy force is needed to make the movement. This force is usually supplied by hydraulic jacks so devised and placed around the circumference of the diaphragm as to push against the completed iron lining of the tunnel. These jacks have cylinders six inches or more in diameter and are actuated with water or other liquid at a pressure of 1,000 to 3,000 or 4,000 pounds per square inch. A shield about 21.5 feet in diame-

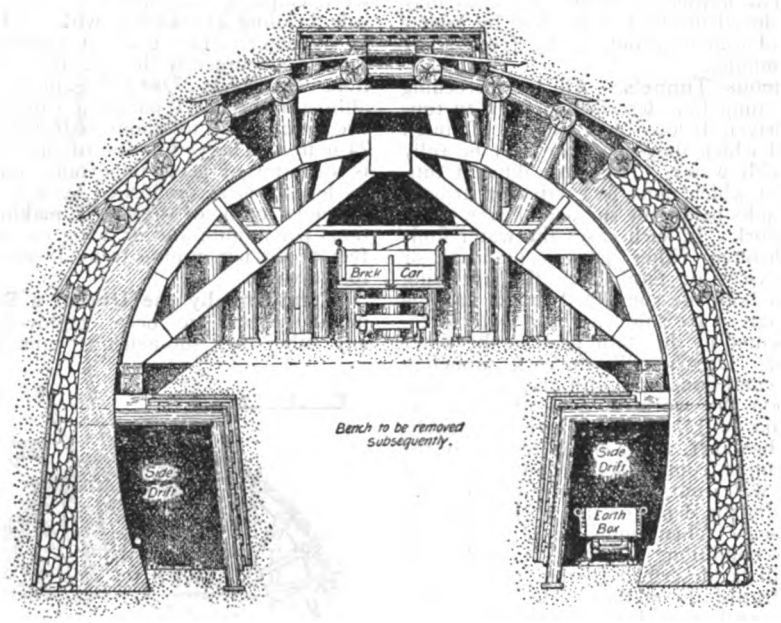

FIG. 7.

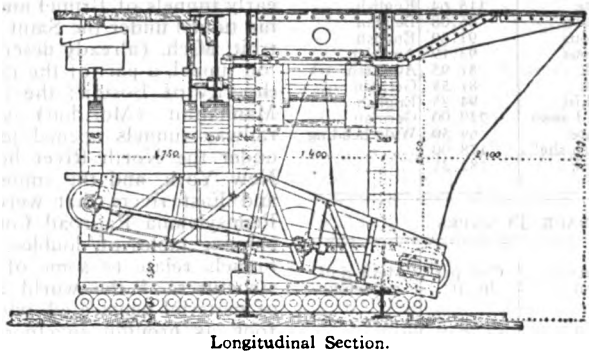
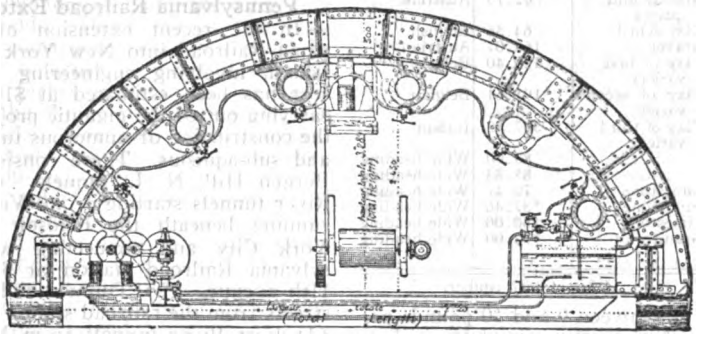
ter was used in the construction of the Sarnia tunnel under the Saint Clair River above Detroit, Mich. This shield was moved by 24 hydraulic jacks, as shown in the illustration, each having a capacity of 125 tons and so placed as to press directly upon the cast-iron tunnel lining behind it. By such means the shield may be pushed ahead as fast as the excavation is made and the tunnel lining completed behind it.

The Saint Clair River tunnel is a single-track railroad tunnel built in 1890–91 by the Grand Trunk Railroad. The total length of the tunnel is 6,000 feet, made up of 1,162 feet on the United States side of the river, 844 feet on the Canada side of the river, and 2,310 feet under the Saint Clair River. It is built through the clay underlying the river and has a clear inside diameter of 19 feet 10 inches, the cast-iron shell being two inches thick and having an outside diameter of 21 feet. The cast-iron shell is lined with six inches of brick and cement. The shield was 15 feet 3 inches long and required from 450 to 2,000 tons to move it during construction. The maximum daily progress through the clay was 15.3 feet. The average monthly progress was 230.4 feet from the American side and 219 feet from the Canadian side.

The transverse section of a shield may be circular, elliptical, or any other shape; it may even be rectangular, as in the case of Brunel's Thames tunnel. The shield for the Clichy sewer tunnel in Paris was elliptical in outline. Again, if the material is not too soft, the shield may be segmental only, that is, comprising but a part of the outline of the full shield, usually the upper part. The shield for the use of the East Boston tunnel recently constructed was segmental and was used for the roof of the tunnel only, as is also shown in the illustrations. The front portion of the cylindrical shell, consisting of the front portion of the shield as a whole, may be vizor-shaped if material is not too soft. In such a case the upper part of the fresh excavation is protected by the vizor extension of the shield. Where the material is stiff enough to hold itself up for a short time the front extension of the shell is not needed.



Longitudinal Section.



Cross Section.

FIG. 8.

It is thus seen that the purpose of the shield is to prevent the inrush of water and soft material while excavation is being made, the diaphragm of the shield acting as a bulkhead and the openings in it being so devised as to be quickly closed if necessary. The extension of the shield in front of the diaphragm is designed to prevent the falling or flowing in of the exposed face of the new excavation. The extension of the shell back from the diaphragm is designed to afford opportunity for putting in place the finished tunnel lining, whether of cast iron or of steel plates lined with masonry. Where the material is saturated with water it is usually necessary to use compressed air in connection with the shield. The intensity of this air pressure is determined by the depth of the tunnel below the surface of the water above it. A greater intensity of pressure is needed for the material at the bottom of the tunnel than at the top, but as the pressure required for the

bottom must in general be used, there will be danger of "blow-outs" at the top, requiring great caution in soft material. With a diameter of shield of 22 feet the pressure at the bottom of the excavation may exceed the water pressure at the top by between 9 and 10 pounds per square inch. Such inequalities tend to produce either a "blow-out" at the top of the heading or an inrush of water and soft material at the bottom. The following table was compiled by Mons. R. Le Gouez and shows the dimensions of the cylindrical shells of some of the principal shields used in tunneling through soft material up to the present time.

The friction on the outside of the shell of the shield against the surrounding material may be over 1,000 pounds per square foot or much less than that. The amount of nominal hydraulic jack power required may be roughly taken at 4,000 to 6,000 pounds to every square foot of frictional surface on the outside of the shell of the shield.

Some of the principal later tunnels constructed by the aid of shields, in addition to the early tunnels of Brunel and others, are the Sarnia tunnel under the Saint Clair River, near Detroit, Mich. (already described); the East Boston tunnel, a part of the rapid transit system of the city of Boston; the two parallel Hudson-Manhattan (McAdoo) single track electric railway tunnels opened to the public in 1908, under the North River between Hoboken and New York, and the tunnels under the North and East rivers that were constructed by the Pennsylvania Railroad Company. The accompanying tables of double-track and single-track tunnels relate to some of the principal tunnel structures of the world and give the quality of material penetrated, with the cost per linear foot, as brought together by Charles Prelini, C.E., in his 'Tunneling.'

Pennsylvania Railroad Extension Tunnels. —In the recent extension of the Pennsylvania Railroad into New York City and Long Island, involving engineering enterprises, the cost has been estimated at $100,000,000. The carrying out of the gigantic project necessitated the construction of numerous tunnels, both land and sub-aqueous. These consist of: (1) The Bergen Hill, N. J., tunnels. (2) The North River tunnels starting from Weehawken, N. J., running beneath the Hudson River to New York City and connecting with the Pennsylvania Railroad station at 33d street, near 11th avenue. (3) Tunnels under 33d and 32d streets from the railroad station to First avenue. (4) East River tunnels from Manhattan shaft of New York City side of the river, running under East River to Long Island shaft and Long Island City.

DOUBLE-TRACK TUNNELS.

Bergen Hill Tunnels.— These consist of two parallel single-track, concrete-lined tunnels 5,920 feet long between portals. The boring through Bergen Hill was largely in trap rock (diabase), partly in sandstone. Some of the former was so extraordinarily hard as to require 10 hours to drill a 10-foot hole in the heading with a number 34 slugger drill at 90 pounds air pressure. Work started May 1905 and completed May 1908. Height of the tunnel inside is 16 feet 2 inches from the top of track rail to crown. The tunnel is lined with concrete variably, according to the soils to be supported. The water proofing is of six-ply felt and seven layers of pitch. Bench walls at either side of tunnel carry conduits for telephone, telegraph, etc.

North River Tunnels.— These extend from 10th avenue, New York City, to the large shaft at Weehawken, N. J., crossing under the Hudson River. They consist of two single-track tubes lined with cast-iron rings, and have an outside diameter of 23 feet, and 21 feet 2 inches inside diameter. The subaqueous portion is 6,128 feet long. Work was started April 1904 and completed 1910. The Weehawken shaft was a large piece of work being over the tunnels and including both. Difficulties occurred from the treacherous nature of the rock, which hindered work till it was lined its entire length with concrete. The tunnels under the river were driven with shields. The floors of two platforms were so constructed that they could be extended 2 feet 9 inches in front of the cutting edge or 8 inches in front of the hood. The motion to the sliding platforms was given by hydraulic jacks. The land tunnels consist of 977 feet of double tunnel on the New York City side and 230 feet on the New Jersey side. The Manhattan end (from 11th avenue to 32d street) is very complicated, having in its 977 feet nine different styles of cross section caused by a curve; for the curve is effected *in straight lengths* not curves. Parts of the land tunnels were shield driven but other parts were open-cut work and ordinary land tunneling, as great variation was found in the nature of the material met with; some soft ground caused some cut-and-cover work. The cast-iron rings of the tube are bolted together through holes in flanges. After lining with concrete the inside diameter of the tube is 19 feet, but after laying the flat bed there is left 16 feet 7 inches from top of rails to soffit of arch. The concrete lining is reinforced with steel rods. Excavating was done under an average air pressure of 25 pounds when air pressure was needed.

Cross Town Tunnels.— These extend easterly from the Terminal Station to permanent shafts east of First avenue under 32d and 33d streets. For an average of 350 feet west from the First avenue shafts there are four tunnels in sound, fairly dry rock which was drilled and blasted, but this Hudson schist varied considerably physically and an ancient water-course was struck causing difficulties. Sand also caused much trouble in spots. Some open-cut work on 32d and 33d streets caused much underpinning of houses. On Sixth avenue the Elevated Railroad was underpinned to rock. Concrete lining is used on these twin tunnels. These two-track tunnels have their crown about 60 feet below street surface. In the three-track tunnel heavy brick arching was used for tunnel lining and concrete for roof of open-cut work. These tunnels were completed March 1909, but roadway restoration required further time.

East River Tunnels.— These connect the cross-town tunnels, by tunnels beneath the East River, with Long Island City. They consist of four single-track, cast-iron and concrete lined tubes with an outside diameter of 23 feet, starting from two permanent shafts on the east side of the river. Each tunnel is about 6,000 feet long, 3,900 feet of which is between the shafts each side of the river and 2,000 feet in Long Island City. The work was finished in exactly five years. The East avenue heading needed at start 15 pounds air pressure for soft ground and considerable water; then rock permitted discontinuance. A shield was soon brought into use but found impracticable except for a short distance under the Long Island passenger station. Solid rock excavating was done with bottom-heading-and break-up or with top-heading-and-bench methods; soft ground in top of rock tunnel was excavated in normal air by mining-and-timbering method. In some parts of this work water was struck and tunneling was done in compressed air *without a shield* by building the iron lining up to face of the full-sized excavation, then top-heading a hole for about 10 feet in advance about 3 feet wide by 4 or 5 feet high, then timbering. A permanent shaft was constructed on the Manhattan side over each pair of tunnels. The four river tunnels between the Manhattan-Long Island City shafts were constructed with shields working both ends at once. One difficulty overcome was that caused by the small depth of roof at the deepest part of the river (at the Manhattan pier-head line) and consisting of fine sand. Safer cover to protect against blow-outs was given by adding blankets of clay on the river bed seven to ten feet thick. Air pressure carried in soft ground work were from 30 to 34 pounds ranging up to 37 pounds in tunnels B and D at Manhattan and up to 42 pounds for short periods to remove broken plates. The chief difficulty was in soft sand allowing the shield to settle, thereby breaking plates in the bottom of the rings. Blow-outs of such severity occurred as to stir up the bed of the river sufficiently to necessitate shutting down work for three weeks to allow the river bed to consolidate and permit further work. Standard cast-iron tunnel lining was used, giving 23 feet outside diameter with rings 30 inches wide, 11 segments and a key to each ring. Inside diameter of tubes is 21 feet 2 inches. There are 1½-inch thick webs in the central portion; flanges are 11 inches deep. In passing from rock to soft ground cast-steel rings were added as reinforcement for a short stretch. The iron tube is line with concrete. For Bibliography see under TUNNELS, GREAT MODERN.

WILLIAM H. BURR,
Professor of Civil Engineering, Columbia University.

TUNNY, or **HORSE MACKEREL**, a large, brilliant and valuable fish of the mackerel family (*Thunnus thynnus*), which occurs in shoals in almost all the seas of the warmer and temperate parts of Europe, Asia, Africa and

America, but is not equally common in every season or in all parts of the seas which it frequents. Immense numbers enter the Mediterranean by the Straits of Gibraltar in May and June and immediately divide, one part following the shores of Europe and the other those of Africa, in search of a place to deposit their spawn. The fishery is one of the most important in the Mediterranean, especially about Sardinia. At the approach of winter the fish retires to deep water. It often, besides, wanders widely and has acquired many local names, as albacore, horse-mackerel, etc. It is not uncommon in the Pacific off Santa Catalina, where it is known as the tuna, and is angled for from small launches that run out to sea. Large examples, and they sometimes attain a weight of 1,500 pounds, fight so determinedly for freedom that many hours are often consumed in mastering them. Tuna are caught off the Atlantic Coast, especially about Block Island during the months of August and September. At times they readily take artificial bait, being fished for by trawling. The large Wilson spoon or squids are used; the larger fish are harpooned. Although readily sold when captured and much relished there is no regular fishery for the tunny in the United States. See MACKEREL.

TUPAC AMARU II, the name assumed by a Spanish-Peruvian adventurer: b. Tinta, 1740; d. 10 Sept. 1780. His name was José Gabriel Condorcanqui and his mother was the daughter of the last of the Incas. He was killed on the failure of an uprising which he had planned.

TUPAIA, or BANXRING. See TREE-SHREW.

TUPELO, Miss., town, county-seat of Lee County, on the Old Town Creek and on the Mobile and Ohio and the Kansas City, Memphis and Birmingham railroads, 100 miles southeast of Memphis, Tenn. It is in an agricultural and stock-raising region. The water supply is obtained from about 40 artesian wells. The chief industrial establishments are cotton presses, cotton-gins, flour mills, spoke factories, furniture factories, brickyards and machine shops. The two banks have a combined capital of $100,000. It has a high school and graded schools. Pop. about 3,881.

TUPELO, one of the several American trees of the genus *Nyssa,* family *Cornaceæ. Nyssa* is found also in Eastern Asia. There are swamp-loving trees, with alternate, entire, or nearly entire leaves, and regular, small, greenish flowers in capitate clusters, the fertile blossoms sometimes solitary, on slender axillary stalks, and appearing with the foliage. The drupe is more or less oval, with a compressed stone. *Nyssa sylvatica* is the sour gum, or pepperidge, growing farther north than the other species, and more apt to be found away from water, and made conspicuous in autumn by the scarlet of its foliage and by the dark-blue fruits, which are a valuable food for migrating robins. When leafless it is still noticeable, for the picturesque growth of its limbs, sometimes in round heads, often horizontal, as if the many knotty branches lay in strata. The bark is rough and gray. The wood is of a light color, but with a twisted grain, which makes it difficult to work. This unwillingness to split, however, makes it desirable for beetle-heads, ox-yokes, hubs of wheels, bowls, etc. Tupelo is durable when completely immersed in water, especially if salt, and is, therefore, of value for ships' keels; but it will not stand alternation of moisture and dryness. The southern mountaineers value it for "chaw-sticks,"—small pieces of the stem, chewed into brushes with which they may dip up snuff. In consequence of its erratic growth and fibre, sour-gum trees were debarred as evidence in boundary disputes, in cases where some time had elapsed after blazing trees, as shown by the condition of the scar. *Nyssa ogeche,* called the Ogeechee lime, from the stream of that name, which is said to be about its northern limit, is an inhabitant of southern river-swamps liable to inundations. Its young branches have a silvery gray back, and the short petioled oval leaves are whitish pubescent beneath, when young, and are about six inches long. It becomes a large tree of handsome but somewhat peculiar habit. The fruit is of the size and shape of an olive (which caused the French in Mississippi to call this tupelo "the olive"), but is scarlet, and of an agreeable acid flavor. It is preserved in sugar. The wood is of little account, being soft, and the roots of one variety are so light that buoys for fishermen's nets were made out of them. *Nyssa aquatica* is the large tupelo, or "cotton" gum, so called because tomentose in all its more youthful parts.

TUPELO, Battle of. In March 1864, Gen. N. B. Forrest, at the head of a large force of Confederate mounted infantry, advanced from Mississippi and made a raid through West Tennessee to Paducah, Ky. Upon his return he assaulted and captured Fort Pillow (q.v.) on 12 April. General Sturgis set out from Memphis to pursue him, and was badly defeated by Forrest, at Guntown (q.v.), 10 June, and pursued back to Memphis. On 5 July Gen. A. J. Smith, with Colonel Grierson's cavalry division, two infantry divisions of Gen. J. A. Mower and Col. D. Moore, of the 16th corps, and a brigade of colored troops, under Col. E. Bouton, in all about 14,000 men—11,000 infantry and 3,000 cavalry—and 24 guns, left La Grange, Tenn., to march southward against Forrest, then reported in the vicinity of Tupelo, Miss. On the evening of the 7th one of Grierson's cavalry brigades, when near Ripley, attacked a Confederate cavalry force of 500 men, under Lieutenant-Colonel Hyams, driving it back and inflicting a loss of 35 killed and wounded, with a loss to itself of four wounded. Smith moved on through Ripley, crossed the Tallahatchie River at New Albany on the 9th and on the 10th encamped about five miles north of Pontotoc. Next morning the march was resumed and Pontotoc was found occupied by McCulloch's cavalry brigade, supported by a brigade on a hill immediately south. The Seventh Kansas cavalry were deployed as skirmishers and, supported by a brigade of infantry, advanced and drove in the Confederate skirmishers and at the same time Grierson's cavalry, gaining the east side of the town, attacked the Confederates in flank and drove them from the place and the hill beyond, leaving several dead and wounded. Gen. S. D. Lee joined Forrest and assumed command of all the Confederate forces. Smith remained at Pontotoc on the 12th and a reconnoissance developed the fact that the main

Confederate force was about nine miles south on the Okolona road, on the opposite side of a low, swampy bottom, through which ran two creeks, a position which he did not deem prudent to attack, and upon which he demonstrated only. Early in the morning of the 13th he marched out of the town eastward for Tupelo, 18 miles distant, on the Mobile and Ohio Railroad. General Lee, informed of Smith's movement, ordered it checked before the railroad was reached. Forrest, with a brigade and a regiment, made successive attacks upon the rear, which was covered by Bouton's colored brigade and the Seventh Kansas cavalry, but was repulsed and kept back, and Buford's and Chalmers' divisions attacked the train in flank, causing the destruction of a few wagons, but were driven back by Mower's division, which captured some prisoners and a battle-flag. At dark Smith camped at Harrisburg, a mile from Tupelo, in good position on a knoll almost clear of trees, beyond which was a growth of timber. Mower's division was drawn up on the right of the Pontotoc road, on which the army had marched, and Moore's division on the left of the road, with Bouton's colored brigade on the extreme left. Meanwhile Grierson's cavalry division had occupied Tupelo, proceeded to destroy the railroad and was then disposed on both flanks of the infantry. Early in the morning of the 14th Lee ordered Forrest to attack Smith's left, and at 7.30 A.M. Forrest, having dismounted his entire command, made an impetuous charge, with four brigades in line, supported by Chalmers' division and Lyons' brigade. The assault fell upon Moore's division and the left of Mower's, but failed to shake either, although four successive attempts were made. Between the assaults Forrest's artillery was very active, but was effectively replied to by two Union batteries, whose fire was so annoying that a brigade charged them but was repulsed. After a hard struggle of one and one-half hours Forrest withdrew from Moore's front, leaving many dead and wounded. He now marched to the left, crossed the Pontotoc road and advanced in three lines against Mower, whose men reserved their fire, until the charging lines, closed in mass, were quite near; then they opened upon them with musketry and canister, driving them back in disorder; but they rallied and renewed the attack. For over two hours the battle raged on Mower's front; then he ordered his division to advance, which it did, capturing many prisoners and driving Forrest from the field about noon. The afternoon was spent caring for the wounded of both armies and burying the dead. About 9 o'clock in the evening Forrest made an attack upon the extreme left of the Union line, including Bouton's colored brigade. The attack was easily repulsed. At an early hour of the 15th Forrest's men advanced from the cover of the woods in front of Mower's division; Mower charged them and they fled to their horses and rode away. Meanwhile another advance was made on the extreme left, held by Bouton's brigade. For two hours there was sharp artillery firing, when Forrest, under cover of his guns, came forward, but was met by a counter-charge, led by Smith, which broke Forrest's line and sent it in retreat. It was now past noon. Smith's ammunition had run low and he had a scant supply of rations. Grierson had destroyed some miles of railroad and after the last repulse of Forrest Smith moved slowly northward about five miles and went into camp for the night at Old Town Creek. The men were settling themselves for a rest when shells from the rear fell and burst among them. Bell's brigade, with a battery, had closely followed the column and attacked; Mower turned upon them; Crossland's brigade came up and joined Bell; but both were repulsed by Mower with severe loss and fell back upon McCulloch's brigade, which held ground. McCulloch was desperately wounded, Forrest was wounded and some prominent officers were killed. Smith resumed his march next morning, followed for two days by two brigades of Forrest's cavalry and reached Memphis on the 23d. Smith had about 14,000 men engaged and his losses, from the 11th to the 15th, were 77 killed, 559 wounded and 38 missing. The Confederate troops engaged numbered about 6,600; their losses, as reported by Forrest, were 210 killed and 1,116 wounded. Consult 'Official Records' (Vol. XXXIX); Wyeth, 'Life of Gen. N. B. Forrest'; The Century Company's 'Battles and Leaders of the Civil War' (Vol. IV).

E. A. CARMAN.

TUPÍAN STOCK. The chief linguistic stock of South America and in its corrupted form the trade medium throughout the Amazon region. The Tupian tribes held the greater portion of the territory when the Portuguese took possession of Brazil and as a rule were superior to the other aborigines. They practised agriculture and were experts in many arts. Their houses were for the most part communal. The Tupían languages have been extensively cultivated. Consult Adam, Lucien, 'Matériaux pour servir à l'etablissement d'une grammaire comparée des dialectes de la famille Tupí' (Paris 1896).

TUPPER, tŭp'ẽr, SIR **Charles,** Canadian statesman: b. Amherst, Nova Scotia, 2 July 1821; d. in England, 1915. He was graduated from Edinburgh University in 1843 with the degree of M.D.; began the practice of medicine in his native town and in 1867–70 was president of the Canadian Medical Association. He entered political life in 1855 when elected as a Conservative to the Nova Scotia assembly and there became a leader of his party in the adoption of a more progressive policy, became provincial secretary in 1857 and in 1864 Premier of Nova Scotia. He took a leading part in bringing about the union of the Canadian provinces and in the organization of the Dominion government, attending the Charlottetown and Quebec conferences and the final conference at London. In 1867 he was elected to the Canadian House of Commons, representing his constituency there from 1867 to 1884, from 1887 to 1888 and from 1896 to 1900. He was president of the Privy Council in 1870–72, Minister of Inland Revenue in 1872 and Minister of Customs in 1873. The Conservative government being defeated in the last-named year, he became one of the principal organizers and leaders of the opposition and brought before Parliament the plan of moderate protection for home industries, subsequently adopted by a Conservative administration. On the return of his party to power in 1878 he entered the government as Minister of Public Works

and in 1879 organized and became first Minister of the Department of Railways and Canals; in this office he greatly assisted the construction of the Canadian Pacific Railway. In 1884 he went to London as High Commissioner of Canada, returning for a time in 1887–88 to become Minister of Finance, but resigned that office in 1888 and resumed his position in London. In 1896 he again returned to Canada to enter the ministry and was Secretary of State until April, when he became Premier; but his party was defeated in June of that year and he was chosen leader of the opposition in the House. He lost his seat at the election of 1900 and retired from public life. In 1887 he was one of the plenipotentiaries to the fisheries conference at Washington, which resulted in the treaty settling the fisheries dispute. In 1879 he was knighted and in 1888 made a baronet. Consult his 'Recollections of Sixty Years' (Toronto 1914); Sanders, E. M., 'The Life and Letters of the Right Honorable Sir Charles Tupper' (1916).

TUPPER, Sir Charles Hibbert, Canadian statesman, son of Sir Charles Tupper (q.v.): b. Amherst, Nova Scotia, 3 Aug. 1855. He was educated at McGill and Harvard universities, taking the degree of LL.B. at the latter in 1876. In 1878 he was admitted to the bar and began the practice of law at Halifax, later practising in British Columbia. He was elected to the Canadian House in 1882 and re-elected in 1883, 1887, 1891 and 1896. He entered the Conservative government as Minister of Marine and Finance in 1888, holding that office till 1894. In 1895 he was Minister of Justice and Attorney-General and for a short time in 1896 solicitor-general. As Minister of Marine, he obtained the passage of several acts providing for the safety of ships and seamen; as Minister of Justice he dealt ably with the Manitoba school question. In 1893 he represented Great Britain in the Bering Sea arbitration tribunal at Paris; in the same year he was knighted. He retired in 1904.

TUPPER, Martin Farquhar, English poet: b. London, 17 July 1810; d. Albury, 29 Nov. 1889. He was graduated at Christ Church, Oxford, in 1832; studied at Lincoln's Inn; was called to the bar in 1835, but never practised, and in 1838 published the original edition of his 'Proverbial Philosophy.' This he expanded into four series (1839–76). The earlier of these went through about 60 editions. By 1881 the work had reached the sale of 1,000,000 copies in America. The readers of it were either those whose ridicule made Tupper synonymous with the egregiously commonplace or those who calmly absorbed the strange effusion with convictions that the author "had eclipsed Solomon." It was summarily treated by reviewers, parodied widely and cleverly and for the years of its popular success remained a favorite butt of the critics. Remarks regarding him may be found in 'Passages from the English Note-Books' of Hawthorne (1870). His other writings, such as 'War Ballads' (1854) and 'Rides and Reveries of Mr. Æsop Smith' (1857), were less conspicuous. In 1851 and 1876 he visited the United States. Consult the autobiographical 'My Life as an Author' (1886).

TUPPER LAKE, N. Y., an Adirondack village in Franklin County, on the northern branch of the New York Central Railroad, about 108 miles northeast of Utica. Its chief industry is lumbering. Pop. about 3,200.

TURA, too'rä, or **TOORA,** Siberia, a tributary of the Tobol, 78 miles west of Tobolsk. Its length is 300 miles.

TURANDOT, an oriental fantasy in verse by the Venetian dramatist, Carlo Gozzi (q.v.), was th fourth of his *Fiabe* (those odd nursery-tale plays) and was produced in Venice, 22 Jan. 1762. To confute the criticisms of his adversaries, that the *Fiabe* owed their success to utilization of magic metamorphoses and scenic mechanism, Gozzi replied with a work from which the supernatural element and complicated stage devices were eliminated. The theme is the familiar Persian tale of the cruel princess averse to matrimony who compels her royal suitors to solve three riddles or to suffer death. This bald subject, already known to European literature from the 'Gesta Romanorum,' becomes amplified in Gozzi's hands into a five act tragi-comedy by the addition of a secondary plot, the love of the enslaved Princess Adelma for the princely hero, Calaf. Gozzi, with his customary anachronisms, places the scene in Pekin and transfers there under the guise of court officials the stock Italian masks, Pantalone, Brighella, Truffaldino and Tartaglia, whose Venetian humor gives the comic contrast to the serious plot. Turandot, the daughter of the gentle Emperor Altoum, has successfully eluded all suitors till Calaf solves the three enigmas. Excepting the third and fourth acts which are cluttered with seraglio bickerings and the insertion of the secondary action, beautiful in the handling of the confession of Adelma's love, the drama maintains its interest remarkably well. Calaf is strikingly poetic in his unswervable love and his detached romantic intensity. His faithful follower, Barach, is a well-drawn type of loyal devotion and self-sacrifice.

Lacking the essentially local appeal of the other *Fiabe,* 'Turandot' was frequently translated into other languages, notably German, and obtained a success far beyond its repute in Italy. Schiller's version for the Weimar stage (1802) surpasses the original in poetic form and pathetic sentiment. The beautiful incidental music of Ferruccio Busoni (1906), the recent translation of Karl Vollmœller (1911), attest to its vitality in Germany. In January 1913 a three-act adaptation from Vollmœller's rendering was played at the Saint James' Theatre, London. This singular favor among foreign nations serves to contrast with the almost complete extinction of the work in Italy. It is true that 'Turandot,' like the other *Fiabe,* was written for a transitory purpose in the conflict between the older dramatic forms and the newer art of Goldoni. The defects of the *fiabesque* drama are less apparent in 'Turandot'; the style, so wretchedly slipshod and full of Venetian colloquialisms elsewhere, rises here to higher flights. Nevertheless, Gozzi in his own country has received scant credit for the merits of this quaint work. Consult Magrini, G. B., 'I tempi; la vita e gli scritti di Carlo Gozzi' (Benevento 1883); Masi, Ernesto, 'Le Fiabe di Carlo Gozzi' (Bologna 1884); Symonds, J. A., 'The Memoirs of Carlo Gozzi' (London 1890); Bithell, Jethro, 'Turan-

dot, Princess of China' (an adaptation in three acts from the German, London 1913).

ALFRED G. PANARONI.

TURANIAN, a designation applied to the so-called agglutinative family of languages — that is, languages in which no proper inflection exists, but in which pronouns are made to adhere to the root of the verb to form the conjugation and prepositions to substantives to form the declension. There must be no proper incorporation between the root and the adhering word; the two must simply lie side by side, agglutinated or "glued" together, but one must not modify the form of the other. The Turanian languages are agglutinative, while the Aryan and Semitic languages are inflectional, and the term Turanian is made to include every language of America, Asia and Europe that is not Aryan or Semitic, with the exception of Chinese and its related dialects. (See CHINESE LANGUAGE AND LITERATURE). Max Müller divides the Turanian languages into two great divisions, the Northern and the Southern. In the Northern he includes five classes, the Tungusic, Mongolic, Turkic, Finnic and Samoyedic. He divides the Southern into four, the Tamulic or Dravidian languages of the Dekkan, the dialects of Bhotan and Tibet, the Taic of Siam and the Malayic of the Malay and Polynesian islands. He groups under these nine classes 116 dialects, to which others add Acadian, the Basque and North American tongues. There is serious doubt among philologists as to whether the agglutinative languages should be classed as a group, under a family designation and Peile, in his work on 'Philology,' published in 1877, expresses the view that "these languages are much too different to give any ground at all for believing that they all belong to the same family." See ETYMOLOGY; LANGUAGE; PHILOLOGY; SCIENCE OF LANGUAGE; SPEECH.

TURATI, Filippo, Italian Socialist: b. at Como, 1857. On graduating in the law at Bologna in 1877 he was appointed counsellor from the province of Milan and later was elected a member of the Chamber of Deputies. He served as editor of *La critica sociale* (1891–1903), the Socialist organ, and became leader of the Italian Socialists until temporarily deposed in 1904 by Enrico Ferri. He was, however, returned to power in 1910 on his reformist policy by the Milan congress.

TURBAN, a distinctive covering for the head, consisting of a long cloth wound around, sometimes enclosing a cap or tarboosh worn by most nations in the Orient and of very various forms in different nations and different classes in the same nation. In Moslem countries the style of the turban frequently indicates the position or rank of the wearer. The Turkish sultan's turban contains three heron's feathers, with many diamonds and other precious stones. The grand vizier has two heron's feathers; other officers but one.

TURBAN-SHELL, a top-shell (q.v.), of the genus *Turbo,* so-called from its fancied resemblance to a Moorish turban; it is one of the commonest shells in the stock of every dealer in trinkets, polished to show its nacreous underlayers or fashioned into some ornament.

TURBELLARIA, the whirl-worms; a class of free-swimming platyhelminthes, characterized by the ciliated epidermis containing rhabdites, a delicate body and usually also a muscular protrusible pharynx. They were named by Ehrenberg in 1831 on account of the microscopic whirlpools produced in the surrounding water by the constant vibration of their epidermal cilia. Some of these forms are minute and resemble infusoria; such are the *Rhabdocœlida* (q.v.). With the exception of certain rare parasitic forms all *Turbellaria* are carnivorous; they overpower the prey, perhaps by the peculiar cutaneous structures (rhabdites) already noted and then suck out the substance of the victim by means of the pharynx. The *Turbellaria* include three orders, based primarily upon the character of the alimentary canal, namely, (1) *Polycladida,* in which the intestinal branches are numerous, radiating from a common cavity above the pharynx; all are marine. (2) *Tricladida,* in which the intestine has three main branches, extending one anteriad and two posteriad from the pharynx. (3) *Rhabdocœlida,* in which the alimentary canal is straight and simple or at most slightly lobed. Almost all species are hermaphroditic, although in many male and female organs are in activity at successive periods rather than synchronously. The reproductive system is always complex. In many instances sperm masses are introduced into the body of a second individual by subcutaneous injection, being implanted in the skin at any point and compelled thus to make their way through the tissues to the proper location.

TURBERVILLE, or **TUBERVILLE, George,** British poet: b. Dorsetshire, about 1530; d. about 1610. He was educated at New College, Oxford, and became a Fellow in 1561 but left without a degree and studied law in London. He went to Russia in 1568 with Thomas Randolph, English Ambassador, and of his latter days nothing is known. He wrote pleasing verses and translated from the Latin and the Italian. Selections from his poems may be found in 'Early English Poetry' (edited by Fitzgibbon, London 1887).

TURBINE, literally that which spins or whirls around; *in mechanics,* a wheel which rotates by the aid of flowing water, air or steam and thus furnishes motive power for machinery. Although the steam-turbine is as old as the Christian civilization it is only within the last half century that it has been fully developed. The ordinary turbine with which we are most familiar is the horizontal water wheel made to rotate by the escape of water through orifices, under the influence of pressure derived from a fall.

Water-Turbine.— There are three recognized types of the water-turbine, (1) the radial; (2) axial; (3) combined or mixed-flow. Turbine wheels are made in various sizes from five to seven feet in diameter, with still larger sizes for extraordinary purposes. Perhaps the most powerful water-turbines in the world are those installed in 1894–95 for utilizing the power of Niagara Falls (q.v.). The supply of water to the turbine is regulated by a gate or gates, which can partially or entirely close the orifice where the water enters or leaves. The speed of a turbine is regulated by opening and closing the gate which admits the water. Where the

power used fluctuates, the speed will fluctuate unless some method is adopted to adapt the power developed to the power utilized. This is usually done by means of a governor, which is so devised that when little power is being used the resulting increase in speed will actuate it to close partly the gate, and when much power is being used, the decrease in speed will actuate it to open the gate wider.

High and Low Pressure.— Turbines are divided into high and low pressure, the former being relatively small, revolving at a high speed, driven by elevated heads of water. The low-pressure turbines are relatively larger, contain a larger volume and run at a lower rate. In the Black Forest, Germany, turbines are running with heads of 72 and 354 feet, and having diameters of 20 and 13 inches, respectively. Low-pressure turbines perform excellent duty with large volumes of water having only nine inches head.

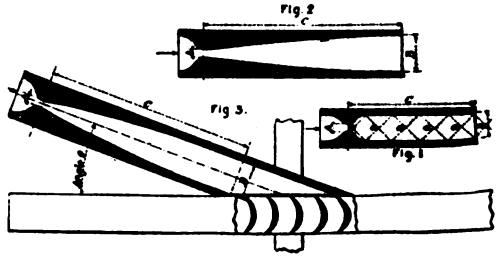
The Radial Turbine.— In radial turbines the water in passing through the wheel flows in a direction at right angles to the axis of rotation or approximately radially. The water may flow inward from the circumference to the centre or outward from the centre toward the circumference. The best-known type of the inward flow is the Francis turbine, and of the outward flow the Fourneyron turbine.

The Axial Turbine, or parallel flow as it is sometimes called, is one in which the water flows through in a direction generally parallel with the axis of rotation. The water may flow from the top downward or from the bottom upward. The best known type of the downward flow is the Jonval turbine.

The Combined Turbine, or mixed flow, is any combination of the radial or axial; that is, the water may flow inward and up or down or outward and up or down. Still another classification is made to distinguish reaction turbines from impulse turbines. In the reaction turbine all parts are filled with moving water, while in the impulse turbine the buckets or other parts are only partly occupied by the water passing over them, the atmosphere having access to the remaining space. A reaction turbine is driven by the dynamic pressure of the water, which may be under a certain static pressure, due to the fact that the inflow takes place under pressure, since the wheel is always filled with water. In the impulse turbine the inflow takes place freely against air pressure only. Most turbines are built on the reaction principle. For a more detailed description of water turbine see HYDRAULICS; WATER-WHEEL.

The Steam-Turbine.— The earliest known steam-turbine was that invented by Hero which is described in an Alexandrian manuscript of about 120 B.C. This was not a practical invention, however, being merely a toy. Little progress was made in the turbine up to the 17th century. Branca made an impulse steam-turbine in 1624, and Edward Somerset followed with a device in 1650. The French engineer Tournaire is entitled to particular mention as having in 1853 indicated the capabilities of the steam-turbine. But the general introduction of the steam-turbine since 1890 is due to the Swedish engineer De Laval and to C. A. Parsons. Thus it is acknowledged that the progress of the steam-turbine is wholly modern and mainly recent. Only after evolution of the modern mathematical sciences could its action be understood and the machine be properly designed; only after modern tools and methods of mechanical construction had become refined could it be built in safe and economical forms. The influence of the Héro toy or Alexandrian invention upon modern engineering is shown to have been of great value. The Hero idea lay dormant during nearly 2,000 years which elapsed between the days of Greek philosophy and modern, practically applied, science.

Modern Development.— Steam-turbines are heat engines, converting the calorific energy of the steam into directly-available mechanical energy. From another point of view they are

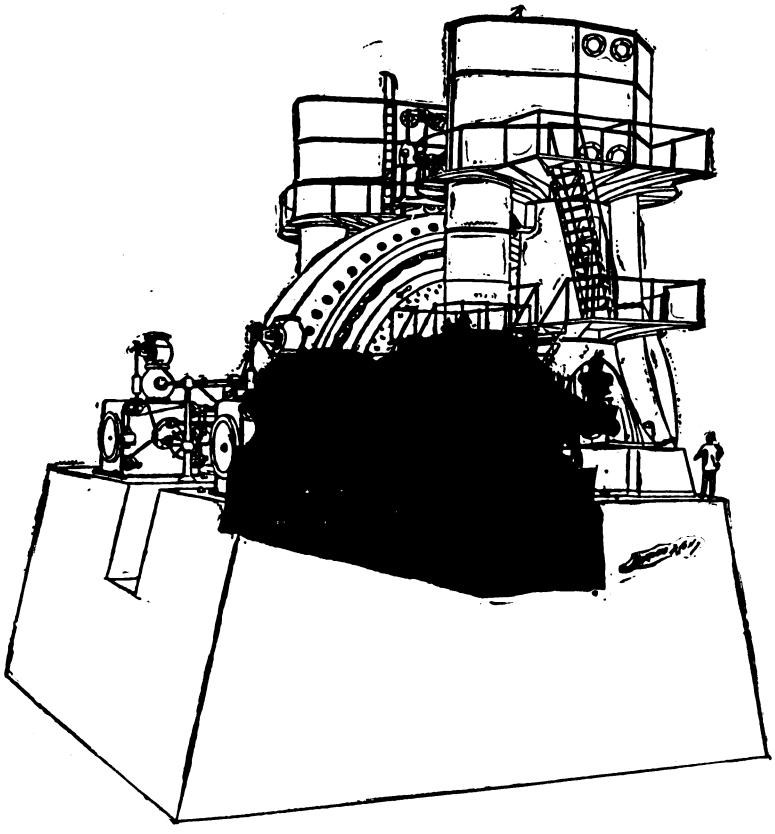


Turbine Jets.

analogous to hydraulic turbines, and in design, construction and operation are controlled by the same ultimate principles. To-day the turbine is more nearly a "perfect steam-engine" than any other known type, so far as its design and construction are concerned. As in the case of hydraulic turbines the steam-turbine is divided into classes; the two principal ones being action and reaction turbines; and each of these classes is subdivided accordingly as the turbine is composed of a single wheel or of several wheels, traversed successively by the steam in course of expansion. Among reaction turbines (compared in hydraulics to the Jonval turbine) of which, as multiple machines, the prototype is the Parsons turbine, the steam is only partially expanded in the distribution and acquires its full expansion in the movable wheel. The steam, therefore, acts on the blades at once by its pressure and its velocity. In the action turbine, the steam only acts on the movable wheels by its velocity. Each wheel revolves in a casing in which the pressure is uniform. Action turbines revolve at a less velocity than reaction turbines. There are now recognized three ways of utilizing steam for the transformation of heat into useful work: (1) By directing a jet of steam on all movable objects, such as the blades of fans, or, in reaction wheels, by allowing the steam passage itself to revolve; (2) by condensing steam in a cylinder and allowing the external atmospheric pressure to force a piston inward; (3) by cutting off slices of high-pressure steam and expanding in the cylinders of the modern reciprocating engine. The present-day steam-turbine designer, however, is merely concerned with the first and oldest method.

The Impulse Steam-Turbine.— The simplest possible steam impulse turbine must consist essentially of a fixed nozzle guiding a jet of steam upon vanes arranged at a periphery of a rotating wheel in a very similar way to the buckets of the water-wheel; but to turn this

wheel efficiently it is necessary not only to make the nozzle of suitable dimensions and shape for the work to be done, but to form the vanes or buckets of the wheel so that they make the best possible use of the steam as delivered from the nozzle. The function of the nozzle is to convert the whole available energy of the steam into mass velocity in the required direction. It should, therefore, be designed so as to expand the steam to the same pressure as that of the wheel chamber before the delivery on the vanes. If the nozzle is improperly formed, either the expansion will not be complete and the jet will burst into a cloud at the orifice, or eddy currents will be set up within the nozzle itself and retardation of flow will be the result. To arrive at the best shape of steam nozzle, the ratio of expansion required should be first decided and the area of entrance — A in Fig. 1 — should bear a relation to the orifice, B, in direct proportion to the increased volume of steam when expanded. The curve of nozzle walls is calculated to allow gradual expansion, until maximum velocity, due to initial pressure energy, is attained. Fig. 1 shows an example of what is found to take place in an incorrectly shaped nozzle. The steam particles rebound from the walls as shown by the dotted lines, and meeting at *a a a a* form points of greatest pressure. Turning again to Fig. 2, if the length, C, is too great, there will be retardation of flow due to the skin friction, and if C is too short the steam will not have time to expand completely. The area at A, then, depends on the quantity of steam to be passed; the area, B, on final pressure required, and the length, C, on the velocity of flow due to the difference between initial and final pressures. The best shape for wheel vane faces is undoubtedly as nearly a semi-circle as is permitted by the angle of the nozzle in Fig. 3. This angle is usually about 20 degrees, which is nearly the maximum possible. While being of sufficient area to reverse the direction of current without shock or eddy, these vanes should be short, so as to minimize skin friction, and the edges should be sharp to avoid blanketing the nozzle. The most efficient mean speed of vanes is just under half the velocity of the steam current, thus leaving the exhausted molecules relatively motionless. For this reason single disc turbines must revolve at enormous speed and be geared down for driving ordinary machinery. For example, a 10-inch De Laval turbine working at 70 pounds' pressure revolves 14,000 times per minute.

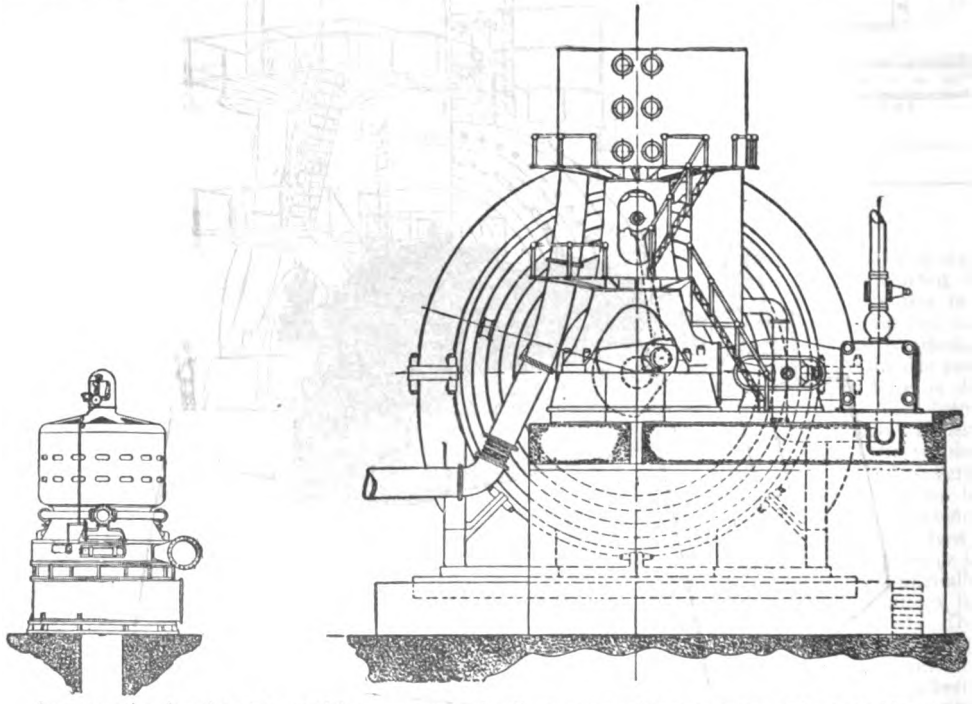


Comparative sizes of Turbine and Reciprocating Engines. (This outline shows a familiar type of vertical reciprocating engine, enclosing a Parsons turbine-generator unit of the same capacity).

The Multiple-Step Plan.— Geared motors are avoided by most engineers, and so the multiple-step steam-turbine was devised as a means for reducing the speed of rotation and driving machinery direct. This idea was first developed

by C. A. Parsons during 1884–87. The earliest Parsons parallel flow turbine was a collection of zigzag nozzles whose walls were formed by projecting rings of blades intermeshing and so arranged that the "zigs" were fixed to the inner circumference of a stationary hollow cylinder and the "zags" to the outer circumference of a rotable cylinder. The modern Parsons turbines from which such notably economical steaming results have been obtained differ from the earliest — apart from improvements in mechanical and constructional detail — only in the alteration of the contour of the steam passages or nozzles from a zigzag to a sinuous shape. Instead of turning sharp corners the steam now traverses flowing curves and the cross-sectional area of steam channels increases in nearly exact proportion to the growing volume of steam as it expands to the exhaust pressure, the collective areas at each stage fulfilling more closely the conditions for a perfect nozzle, as previously mentioned. But as expansion takes place both within fixed and moving blades, as the whole passage is one continuous nozzle, the clearances and workmanship must be of the finest to minimize leakage, which in the earlier machines caused serious trouble.

Professor Curtis of New York has designed large steam-turbines which follow Parsons' very closely in theory, but are differently worked out mechanically. Few revolving discs of comparatively large diameter are arranged, and the fixed steam nozzles only play upon part of their periphery, in some cases only two nozzles being employed on the first disc. Provision is made for altering the nozzle areas according to load by opening or closing their tapered walls, thus to a certain extent permitting correct maintenance of expansion ratios for varying steam pressures and loads. Professor Curtis argues that his arrangement of a few large nozzles and wheels in series lessens the percentage of waste through spilling of steam. In order to reduce the revolutions per minute as far as possible, Mr. Parsons appears to advocate a large number of turbines in series of small diameter, while Professor Curtis believes in few wheels of large diameter. Prof. A. Rateau of Paris has worked out a multiple step impulse steam-turbine, consisting of a number of Pelton or Laval wheels arranged in series on a shaft, each wheel revolving in a separate chamber. Distributing nozzles convey the steam to the wheel vanes, and the whole of the expansion is accomplished within the fixed nozzles. The steam leaves the chambers at almost the same pressure at which it enters, the wheel vanes merely receiving the impulse due to the velocity of the particles; there is, therefore, in this case no tendency to leakage and no necessity for clearance.



A comparative elevation of a 5,000 kilowatt steam-engine direct-connected to a generator, and a 5,000 kilowatt Curtis steam-turbine connected to a generator, showing economy of space.

The Dow Turbine.— The turbine invented by Dow is an inward-flow wheel with concentric sets of guides and vanes in series, and is said to have attained 35,000 revolutions per minute, working regularly at 25,000, consuming 45 pounds of steam per horse power per hour. The Dow turbine, as built for work in connection with the Howell torpedo, gives an average of about 11 horse power in coming up to speed in regular working, at 60 pounds steam-pressure, and weighs from 100 to 150 pounds, or not far from 13 pounds per horse power. Its fly-wheel rim attains a speed of nearly seven miles

a minute at 10,000 revolutions per minute. The designer estimates its power at 150 pounds steam-pressure and the same speed at 40 horse power, or one horse power to three and seventy-five hundredths pounds weight, and states that this may be still further reduced to the extraordinary minimum of two and one-half pounds weight per horse power, a figure within the estimated allowable maximum for use in aeronautic work. These engines have been successfully employed in driving electric machinery and in "spinning" the "fly" of the Howell torpedo. For alternating currents, this system possesses the peculiar advantage of permitting a "dynamo" to be employed having but two poles. In the United States the substitution of the Dow turbine for the system previously in use for spinning torpedoes has brought down the weight and volume of machinery from the earlier minimum of 360 pounds and three cubic feet per machine to 55 pounds and one cubic foot.

The Tesla Turbine.— About 1910 Nicola Tesla exhibited a remarkable 100 horse-power engine, so light that an ordinary man could hold it at arm's length. It was a steam turbine utilizing a new principle. He made a wheel of parallel circular plates about three-sixteenths inches apart and boxed it in, with apartments at the centre and the periphery. Admitting steam at the periphery in a tangential position, the steam rotated the plates by side friction, and continuing around in reducing spirals continued to give out its propelling face as its speed reduced. Thus it was doing the work of a multiple expansion engine with uniquely simple apparatus. The spent steam escaped at the centre. Though most wonderful in theory, this machine has not become commercially useful. See STEAM; STEAM-ENGINE.

TURBINE NAVIGATION. The application of steam-turbines (see TURBINE) to torpedo boats, destroyers and cruisers is to be anticipated from their unique capacity for developing great power and high speed with light and compact machinery. The conditions in a fast passenger steamer are favorable to the economical application of steam-turbines, and in such steamers the smoothness of their running will be a strong recommendation. C. A. Parsons, who has made remarkable developments in the steam-turbine, claims many advantages for the marine turbine engine. Among these many advantages he gives the following: (1) increased speed; (2) increased economy of steam; (3) increased carrying power of vessel; (4) increased facilities for navigating shallow waters; (5) increased stability of vessel; (6) increased safety of machinery for war purposes; (7) reduced weight of machinery; (8) reduced space occupied by machinery; (9) reduced initial cost; (10) reduced cost of attendance on machinery; (11) diminished cost of upkeep of machinery; (12) largely reduced vibration; (13) reduced size and weight of screw propellers and shafting. It may be said, generally speaking, that the larger scale on which the engines are made, the simpler is the construction, the higher the steam efficiency and the lower the speed of rotation.

The Turbinia Experiments.— In 1894 the steam-turbine had developed to such an extent that a syndicate was formed to apply the turbine to marine work, and a vessel, appropriately named the *Turbinia,* was built to develop high speed and to secure determinative measures of the value of steam-turbines in driving the screw-propeller. The first outcome of the experiment on the *Turbinia* was the discovery of a previously unsuspected cause of inefficiency at high speeds of rotation of the screw such as were adopted in this construction — "cavitation" by centrifugal action about the screw, which worked in a self-created cave in the midst of the water, throwing out the water faster than it could flow into the space by the action of gravity, even reinforced by the often still more active tendency to fill the vacuum thus caused. It was only when the speed of rotations of the screws had been reduced to 2,000 revolutions per minute, and after they were set in series of three on the same shaft, that the little boat made her famous run and attained a speed of 32¾ knots an hour, and later of 34½. The trials of the *Turbinia* were reported as follows:

"The mechanical friction of the turbines is particularly small, and the work spent on friction is not materially increased by increasing the range of expansion. This allows the steam to be profitably expanded much farther than would be useful or even practical in an engine of an ordinary kind. Apart from questions of friction the addition of weight and bulk to allow for this extended expansion would be enormous in the ordinary engine; in the turbine it is very moderate. Steam is expanded nearly 200-fold in the *Turbinia* and this is accomplished with engines which are much lighter than reciprocating engines of the same power, although in these the expansion would be much less complete. Rough weather was met with in some of the trials, but the *Turbinia* proved to be a good sea boat. The machinery worked with perfect smoothness, the screws did not race and the bearings remained perfectly cool throughout. From first to last during the whole of the trials, there was no hitch whatever or difficulty of any kind in the action of the turbine. Some 20 were made under various conditions as to speed, the range of speeds tested extending from 6¾ knots to 32¾ knots. Two successive runs on the measured mile in opposite directions in smooth water and at the slack of the tide gave the following data:

TRIAL OF TURBINIA.

Time on the mile, first trial, 109½ sec.; second trial, 110 sec.
Corresponding speed in knots, first trial, 32.79; second trial, 32.73.
Mean speed in knots, 32.76.
Revolutions per minute, of high pressure and intermediate shaft, 2,230.
Revolutions per minute of low-pressure shaft, 2,000.
Steam pressure in boiler by gauge, 210 pounds per square inch.
Steam pressure on admission to high-pressure turbine, 157 pounds per square inch.
Greatest pressure in stokehold by water gauge, 7½ inch.

The speed reached during this trial, 32.76 knots, in the mean was the highest recorded for any vessel. It is greatly in excess of the speed hitherto reached for a boat so small as the *Turbinia.* It is clear that the exceptional speed developed in the *Turbinia* has been achieved without sacrifice to economy, and that the substitution of turbines driving high-speed screws in place of reciprocating engines driving

screws of much more moderate speed is not attended with increased consumption of steam so far as fast running is concerned."

The Viper Destroyer.— The success of the *Turbinia* led to the construction in 1899 of a naval "torpedo-boat destroyer," *Viper*, and this craft, only 210 feet in length, of 375 tons displacement, developing 11,000 horse power, on 15,000 square feet of heating and 376 feet of grate surface, in water-tube boilers, with steam at 175 pounds by gauge; at 1,050 revolutions of the turbines, made over 37 knots, above 43 miles an hour. The contract speed was 35 knots. The turbines were two high and two low pressure, each driving a separate shaft carrying two propellers. The turbines were 35 and 50 inches in diameter. No vibration was produced by the engines, and the engine-room was so quiet that it was hardly possible to realize the presence of engines developing over 10,000 horse power. Here, as in all craft of the sort, the extraordinary performance in power production, once all is understood, is that of the boilers; that of a horse power for each one and one-half square feet of heating surface, and from each square foot of grate about 30 net horse power. This is probably the most extraordinary phenomenon in this or any other example of marine engineering. For warships of the destroyer class the absolute maximum of possible speed is the first thing to be desired, and the expenditure necessary to secure the extra speed is a matter of comparatively small importance.

The Turbine Passenger-Steamship.— In 1901 the turbine for passenger steamships was first adopted on the *King Edward VII*, a passenger steamer of a type in common use on the Clyde, built by William Denny Brothers of Dumbarton, Scotland. The builders, the Parsons Turbine Company and a captain of long experience in the Clyde passenger trade and the steamers by which it is carried, were all equally interested in the venture. To insure that accurate data on which the performance of the turbine might be obtained, the *King Edward* was modeled as nearly as possible of the same size and same general design as the paddle steamer *Duchess of Hamilton*, one of the crack steamers running on the route for which the *King Edward* was designed. The latter is, however, of slighter greater draft and more displacement. The weight of the motors, condensers, steam pipes, auxiliaries connected with the propelling machinery, shafting, propellers, etc., is 66 tons; which works out at about half the weight per indicated horse power of the engines required for paddle steamers of the same type. Another advantage secured to the boat by the adoption of the turbine engines is increased deck space for passengers.

Steam is raised in a double-ended Scotch boiler of the ordinary type, 20 feet long by 16 feet 6 inches in diameter. There are four furnaces at each end, made to work under forced draft with closed stokehold. For purposes of comparison, the capacity of the boiler under these conditions might be set down roughly at about 3,000 indicated horse power. It is, however, in the steam-turbine — the first engine to realize the dream of a perfect steam-driven rotary engine — that the chief interest in the craft is centred. The principle of the turbine is fortunately simple enough to make it easy of explanation. Inside the cylinder to which the steam from the boiler is led is a drum or hollow shaft studded with row upon row of blades or vanes, all set at an angle to the flow of the steam as the sails of a windmill are set to the breeze. It is apparent that the rush of steam deflected from its course by the first row of blades would not reach the next in such a directtion as would allow it to do its work effectively. To meet this difficulty there are, between each row of the working blades, a row of guide-blades fixed to the inside of the cylinder casing and set at the reverse angle. These blades are stationary and their sole purpose is to again alter the direction of the flow of the steam and bring it back to the straight course from end to end of the cylinder before it meets the next succeeding row of working blades. The tops of the revolving blades reach nearly to the outer casing of the cylinder and the stationary blades project inward until they almost scrape the revolving shaft or drum. A series of turbine wheels on one shaft are thus constituted, each one complete in itself, like a parallel-flow water-turbine; but, unlike a water-turbine, the steam, after performing its work in each turbine, passes on to the next, preserving its longitudinal velocity without shock, gradually falling in pressure on passing through each row of blades, and gradually expanding. There is no rubbing friction and no wearing parts except the bearings on which the main shaft or drum revolves.

Following are the net results of the comparative trials:

	Duchess of Hamilton	King Edward
Coal,	1,758 tons, 13 cwt.	1,429 tons, 16 cwt.
Mileage,	15,604	12,116
Miles per ton,	8.87	8.47
Number of days run,	111	79
Daily average consumption	15 tons, 17 cwt.	18 tons, 2 cwt.
Average speed,	16¼ knots.	18¼ knots.

The success of the *King Edward* was so pronounced that arrangements were at once made to construct other vessels of the same type, to be engined also with the steam-turbine. Larger and yet larger ocean-going vessels are being built and equipped with turbine engines, which have demonstrated their many advantages. See also STEAM VESSELS; STEAM-ENGINES

GARDINER D. HISCOX, M.E.

TURBIT, a breed of domestic pigeons, having a small flattened head and very short beak, a crest and a ruffled breast. The colors are various, but usually the body is white and the wings are colored.

TURBOT, a European flounder (*Rhombus maximus*), brown and speckled in color and usually weighing about 10 pounds, and exceptionally as much as 40 pounds, which is famous as a delicacy. It inhabits rather shallow waters in the Mediterranean and in the Atlantic, but is rare northward of Scotland. Like the other flatfishes it lies on the bottom concealed by sand with which it covers itself partly and seizes such small fish as approach, displaying much activity in their pursuit. It spawns during the spring and early summer and full-grown females deposit between 5,000,000 and

10,000,000 eggs. In the early stages of development the eggs are buoyant, but later sink to the bottom. The turbot is an important food-fish and much esteemed in England and on the Continent. Some are taken on hand-lines, but the bulk of the supply comes from the trawl-fishery in the English Channel. The nearest representative of the turbot on our Atlantic Coast is the window-pane flounder (*R. maculatus*), so called on account of its rhomboidal shape and a slight translucency, but this has very little value as a food-fish.

TURCHIN, tėr'chin, **John Basil** (IVAN VASILEVITCH TURCHININOFF), Russian-American soldier: b. province of Don, Russia, 30 Jan. 1822; d. Anna, Ill., 19 June 1901. After his graduation at the Artillery School, Saint Petersburg, in 1841, he entered the service as ensign, participated in the Hungarian campaign and afterward was graduated in 1852 at the military academy for officers of the general staff. After the Crimean War, in which he attained the rank of colonel of the Imperial Guards, he removed to the United States and adopted the profession of civil engineering. When the Civil War broke out he was commissioned colonel of the 19th Illinois volunteers and came to command a brigade under General Buell in Tennessee. He proposed a plan that proved successful in the capture of Huntsville and in recognition of this service he was made brigadier-general. After the war he returned to his profession as civil engineer. In 1873 he founded in Washington County, Ill., the Polish society of Radom. He contributed to scientific and military periodicals and wrote 'Military Rambles' and 'The Campaign and Battle of Chickamauga.'

TURCO-ITALIAN WAR 1911-12. Ever since the occupation by France of Algeria and Tunis in 1882, Italian statesmen had been more or less preoccupied with the question of Tripoli and Cyrenaica, the last remnants of Turkish dominion in Africa. On the northern coast of the Black Continent, that strip which belongs to Egypt was to all intents and purposes already British, though nominally still under Turkish suzerainty; French Algeria and Tunis stretched westward almost to Gibraltar, to the borders of Morocco. Only Tripoli and Cyrenaica were Turkish, wedged in between British and French boundaries. All that Italy possessed outside the homeland was a matter of 185,000 square miles on the east coast of Africa — Eritrea and Italian Somaliland, and the tiny concession at Tientsin, China. Her efforts to found an over-seas empire had not met with success; continually instigated by Bismarck to launch out in colonial enterprises wherever she might risk a collision with France or Great Britain, Italy had come to grief at Adowa in 1896. But she had coveted Tripoli long before the Abyssinian disaster. In 1890 Premier Crispi wrote privately to Lord Salisbury: "If we had Tripoli, Bizerta would no longer be a menace for Italy nor for Great Britain." It was suspicion of France, fostered by Bismarck, that had led Italy into what became known as the Triple Alliance; but that suspicion had died out in time and given place to a *rapprochement* between the two Latin nations. Bismarck had persistently refused to extend the Alliance to the Mediterranean, where Italy's chief interests lay. At the time Crispi wrote about Tripoli to Lord Salisbury, France and England were avowed enemies, hence Italy's aspirations had to follow the British statesman's advice, namely, to wait. Crispi fell in 1891, and the occupation of Tripoli waited for 20 years. The accession of M. Delcassé to the French Foreign Office in 1898 changed the history of Europe. He settled the Fashoda crisis with England, arranged a treaty of commerce with Italy and inaugurated that Mediterranean policy which led to the Anglo-French Entente, secured British establishment in Egypt, the French protectorate over Morocco and secret acquiescence (in 1901) to the Italian seizure of Tripoli. About 1902 Italy began to adopt a policy of "peaceful penetration" in Tripoli and Cyrenaica by founding a number of undertakings, commercial and industrial, throughout the territories. The Bank of Rome provided the capital to build grain elevators, electrical works, factories, etc., gradually securing a kind of mortgage on the province that might, if necessary, provide an opportunity for armed intervention. It was only a question of time that such opportunity should arise, for the Turkish authorities placed every possible obstacle in the path of economic development and made the most strenuous efforts to thwart the Italian ventures. All the undertakings languished, the invested capital remained unproductive and bankruptcy loomed on the horizon. Early in 1911 the manager of the Bank of Rome informed his government that he was preparing to enter into negotiations with an English and a German group of financiers, driven thereto in the interests of the shareholders (*Revue des deux Mondes,* 1 June 1912).

According to M. René Pinon, this undesirable prospect greatly contributed to the determination of the Italian government to intervene by force of arms if other measures should fail. There was another consideration that made it incumbent for Italy to hasten matters to a crisis. Germany, one of her partners in the Triple Alliance, was preparing to forestall her in the move on Tripoli, with the intention of acquiring a coaling station on the North African Coast. Public opinion in Italy was ripe for a military adventure; for some decades a kind of "nationalist" movement, headed by enthusiastic young officers and literary men, had gained many adherents to the tenets of imperialism and colonial expansion. On the other hand, there were many of the older type of Garibaldians who regarded the raid on Tripoli as an act of brigandage. From the beginning of September 1911 the position in Tripoli was hotly debated in the press, the Turks being accused of injustice to Italians and of intriguing with Germany. The Turkish transport *Derna* arrived at Tripoli on 26 September laden with guns and munitions. Italy delivered an ultimatum on the 27th giving Turkey 48 hours in which to accept the occupation of Tripoli by Italian troops and an Italian administration, with the proviso that the Sultan's sovereignty should be secured and an annual tribute paid by the new protectorate to the Porte. An Italian fleet was already stationed off Tripoli; an expedition under General Caneva set sail from Italian ports. On 29 Sept. 1911 Italy declared war, secure in the moral

support of the French and British governments. Tripoli was blockaded on the 30th; two days' bombardment easily smashed the Turkish defenses, and the city was occupied on 5 October. Though the attacking vessels were only three or four miles from the land, not one of the few Turkish shells that were fired struck anything. The Turks themselves sank the *Derna* and another small steamer. Including reserves, the Turks had about 8,000 men in Tripoli. The defenses of the town were old-fashioned, of concrete, equipped with obsolete guns. The enormous disparity between the feeble Turkish navy (of four battleships and two cruisers) and the powerful, modern Italian fleet rendered it most unlikely that Turkish reinforcements should be sent to Tripoli by water, and no other way existed. On 29 September Italian warships sank some Turkish torpedo-destroyers off Prevesa in the Adriatic, which led Austria to forbid any further operations in those waters, thus obliging Italy to restrict her naval campaign to the Tripolitan Coast and the Red Sea, the Ægean Sea being also barred. By the time the Italians landed in Tripoli the Turks had withdrawn 10 miles inland. Italian transports poured fresh troops on different parts of the coast, including 10,000 at Benghazi, which was captured on 20 October, and Derna on the 18th. The Italians expected that the Turkish troops would surrender and that the native Arabs would yield to the invasion, but both Arabs and Turks joined forces and fought valiantly. Around the town of Tripoli, which stands on a little peninsula, the Italians erected an entrenchment of about 10 miles facing the desert. Nesciat Bey, the Turkish commander, attacked through the oasis on 23 October; the Arabs behind the Italians in the suburbs suddenly attacked in the rear. The Italians were only able to save themselves after a long and desperate fight. On 26 October another attack took place, but was repelled with considerable Italian losses. On 5 Nov. 1911 the Italian Official Gazette published a decree declaring the annexation of Tripoli, which General Caneva read in the presence of the troops and the natives. The annexation was by no means complete, however, for the obstinate resistance of the Turks and the Arabs hindered the Italians from advancing very far from the coast. The Arab rising had been accompanied by hideous cruelties toward captured Italian soldiers; its suppression was marked by equally savage reprisals and a wholesale slaughter on the Italian side. Deplorable details were published by foreign newspaper correspondents together with photographs taken on the spot. Turkish officers by some means got into the country, reorganized the troops and soon took the offensive by continually harassing the Italian lines. One of the officers was Enver Bey, who afterward stated in a newspaper article, "I found 900 desert warriors when I came here, and now I have under me 16,000 trained soldiers." He said that on one occasion his little army had captured two machine guns, 250 rifles, two cannons, 30,000 cartridges and 10 mules from the enemy. In November 1911 the Italians made preparations to attack the Dardanelles, but the plan was vetoed by Russia. Early in November the Italians recaptured two positions which they had evacuated in October; and on 4 December forced the Turks to abandon their base at Ain Zara, which they fortified. On 19 December an Italian column narrowly escaped annihilation. By the end of the year the Italian press grew restive and inclined to blame Germany, Austria and France for the obstacles to Italian success. France and England were accused of upholding traffic in contraband of war, and energetic steps were demanded from the navy. In January 1912 the Italians had 100,000 men at the front; Enver Bey commanded about 15,000 Turks around Benghazi, and some 10,000 or 12,000 were located at Tripoli. Up to April the Italians remained on the defensive, repelling violent Turkish attacks. In January two French vessels were seized on suspicion of carrying contraband. France protested, and the vessels were released. During February and March the Italians captured several strong positions; near Benghazi the Turks were completely defeated and two small Turkish warships were sunk in the harbor of Beirut. Since January 1911 Turkey had been endeavoring to quell a rising in Yemen, and had for that purpose moved troops from Tripoli — before the Italian ultimatum — and sent them to Arabia. In January 1912 Italian warships entered the Red Sea, sank several Turkish gunboats and bombarded Jebel Tahr, Hodeidah and Loheia, besides dropping shells on various Turkish camps and hampering the Yemen operations by declaring a blockade of the coast. On 25 March 1912 the German emperor intervened in person by meeting the king of Italy at Venice. But his mediation proved fruitless, owing to Germany's double rôle as Turkey's protector and Italy's ally. In April an Italian force landed near the Tunisian frontier at Zuara and cut the main artery of the contraband smuggling business. An Italian squadron now approached the Dardanelles and bombarded the outer forts (18 April 1912). The Turks promptly closed the straits to all shipping, with remarkable consequences. The loss to Russian grain export quickly amounted to many millions. England, Bulgaria, Greece and Rumania lost some $100,000 per day each; British steamers, headed for the Black Sea, had to be diverted through the Suez Canal toward Indian markets; on 2 May 1912 there were 185 idle vessels anchored east and west of Constantinople. Yielding under powerful representations from European governments, the Turks reopened the Dardanelles on the 10th of May. On 5 May a strong Italian force landed at Rhodes, on the island of that name, occupied the capital and 10 days later compelled the Turkish garrison to surrender. They also occupied the islands of Neros, Karki, Stampalia, Piscopos, Scarpanto, Patmos, Casos, Kalminos, Karpathos, Kos, Lipsos and Simi. On 8 June the troops in Tripoli defeated a Turco-Arab force at the oasis of Zanzur and on the 15th General Camerana attacked near the oasis of Misrata, which was taken in July. Heavy fighting took place on the western frontier during June, July and August. By slow degrees the Turks and Arabs were driven back until the whole western coast-line was in Italian hands. On 5 Sept. 1912 General Caneva was recalled and two separate commands were formed for Tripoli and Cyrenaica. During the night of the 12th July five Italian torpedo-boats en-

tered the Dardanelles to attack the Turkish fleet lying above the Narrows. But the entrance to the Narrows was barred by thick steel cables at Kilid Bahr and they had to retire under heavy fire from the shore batteries. This was the last naval operation of the war. In September it leaked out that peace negotiations between Italy and Turkey were in progress under a veil of mystery in Switzerland. Each side was anxious to end the war: Turkey, to prepare for another war that hung over her head, and Italy, to recover her freedom of action in Europe. Meanwhile, fighting continued in Tripoli. On 22 September a strong Turco-Arab position south of Zanzur was attacked and captured. During the middle of the month Enver Bey attacked the Italian positions at Casa Aronne and Kasr-el-Lebn in Cyrenaica. In a fierce battle the Turks were repulsed with heavy loss. A few miles eastward the Italians stormed Sidi Abdullah and occupied Bombah on 7 Oct. 1912. On the next day Montenegro declared war on Turkey — the overture to the Balkan Wars (q.v.). On the 12th a hitch occurred in the peace negotiations. Italy was preparing for further naval operations, and for the moment it seemed that she would become an ally of the Balkan League (q.v.). Turkey needed peace with Italy at all costs to prevent this; besides, Italian command of the Ægean hindered Turkey from sending troops to Macedonia. The Italian terms were accepted in full and the Peace of Lausanne was at last signed at Ouchy on 15 Oct. 1912. Turkey bound herself to withdraw her troops from Tripoli, but did not recognize the sovereignty of Italy; she was to have a representative to watch over the interests of Mohammedans in Tripoli. On her side, Italy was to restore all the captured Ægean Islands, on condition that a full amnesty should be granted to their inhabitants, and their autonomy respected: she was to pay that part of the Ottoman Public Debt which is guaranteed by revenue from Tripoli and Cyrenaica. Consult Irace, Chevalier Tullio, 'With the Italians in Tripoli: The Authentic History of the Turco-Italian War' (London 1912); Fullerton, W. M., 'Problems of Power' (London 1913); McCullagh, F., 'Italy's War for a Desert' (Chicago 1913)

TURDIDÆ, Turdus, the family and genus of the typical thrushes.

TURÉNNE, Henri de la Tour d'Auvergne, ŏñ-rĕ dĕ lä toor dō-värn-y tü-rĕn, VICOMTE DE, French commander: b. Sedan, 11 Sept. 1611; d. Sasbach, 27 July 1675. He learned the art of war under his uncles Maurice and Henry of Nassau, and in 1630 entered the service of France. In this service he distinguished himself in Lorraine and northern Italy, and in December 1643 he received from Mazarin the command of the army of the Rhine. In August 1646 he succeeded, by a series of skilful maneuvers, in forming a union with the Swedes under Wrangel, and along with him defeated the Bavarians at Zusmarshausen, and compelled the elector to agree to a truce (March 1647). During the disturbances of the Fronde, which began in 1648, he at first sided with the malcontents; but after the death of his elder brother he changed sides, and defended the court against the Prince of Condé, who had previously been the main support of the court party. The victories of Turenne at Bléneau on the Loire (April 1652), and in the suburb of Saint Antoine at Paris (July 1652), led to the termination of the civil war and the complete triumph of the court party; but during these disturbances the Spaniards had taken up arms, and now under Condé, who was so exasperated with the court that he joined the enemies of France, invaded Artois. Turenne was sent to repel the invasion, and gained a victory at Arras in 1654. But the war was prolonged for several years. At last his victory on the downs near Dunkirk in 1658, and the capture of Dunkirk itself in the same year, prepared the way for the Peace of the Pyrenees, which was concluded in the following year. In 1660 he was named marshal-general of the camps and armies of France. When the war was renewed with Spain in 1667 Turenne conquered Flanders in three months, and in the following year subjugated Franche-Comté in as many weeks. In the Dutch War of 1672 he had the chief command and earned greater renown by his exploits during this war than in any other. Turenne first marched against the elector, Frederick William of Brandenburg, and having driven him back as far as the Elbe forced him to sign the Treaty of Vossem in 1673. In the winter campaign of 1674–75, which was signalized by the victories of Sintzheim, Mulhouse (1674), and Turkheim (1675), he delivered Alsace, which had been given up for lost by the minister of Louis XIV, from the imperial troops. This is the most brilliant campaign of his whole career. He was killed at Sasbach while making his preparations to engage Montecuculi.

TURFAN, toor-fän', Eastern Turkestan. an important city on the south slope of the Tyan-Shan Mountains and on a tributary of the Tarim River. Its once important trade declined seriously in 1860–70 owing to the troubles in Kashgar. Pop. 30,000.

TURGAI, toor-gī'. Russian Central Asia, a sparsely populated district lying south of the government of Orenburg, and north of the Aral Sea. Area, 169,832 square miles. Pop. 706,200. It is traversed in the west by the southern extremity of the Ural Mountains. The rest of the country is steppes inhabited by Kirghiz and their herds.

TURGÉNIEF, Iván Sergyéyevitch, Russian novelist: b. Orel on the Oka, 9 Nov. 1818 (N. S.); d. Bougival, 3 Sept. 1883. He belonged to an old aristocratic family. One of his ancestors, Pyotr Turgénief, was executed on the Lóbnoye Myésto in Moscow for attempting to unmask the False Dmitri. Another, Yákof Turgénief, was the famous jester of Peter the Great, who suggested cutting off the patriarchal beards of the Boyars. Iván's father, Sergyéï Nikoláyevitch, was a member of the Yelisavyetgrad regiment of cuirassiers serving at Orel, where he married Varvára Petróvna Lutvínova, and retired with the rank of colonel. In 1820 he took his wife and three sons to western Europe. At Bern, when about four years old, Ivan narrowly escaped the fate of the children that mocked Elijah: he was looking at the bears and if his father had not seized him by the leg in time he would

have tumbled into the pit. On returning to Russia he was given the usual education of wealthy landowners. He always regretted that his native language was not included in the curriculum. What he learned of Russian poetry and legend came to him by the mouth of one of his mother's serfs who introduced him to the 'Rossiad,' the first Russian book he ever read. In 1828 the Turgéniefs removed to Moscow and Iván entered the university when he was 16, but in 1835 he was transferred to the University of Saint Petersburg, where he finished his studies as Kandidat in the department of philology. He had already felt the impulse to write, and he tells in his 'Recollections' how in 1837, under the eye of Professor Plétnyef, he composed "one of the first fruits of his Muse, a fantastic drama in pentameters, entitled Sténiya, and childishly imitative of Byron's 'Manfred.' The professor, without mentioning its author's name, read it in class and afterward meeting him in the street assured him that there was "something in him." This encouraged him so much that he took to Plétnyef some of his other verses, two of which were printed in the *Sovereménnik* (*Contemporary*). One of them was entitled 'The Old Oak.' In 1838 he went to Berlin, under the illusion that real education was to be obtained only abroad. There he spent about two years, studying philosophy, ancient languages and history. Hegel had a great influence on him. Thus he, as it were, cut himself off from Slavic influences and became a westerner, which, as he himself said, he always remained. On returning to Russia, he went directly to Moscow, where lived his mother, a stern, autocratic and even violent woman. There are many dreadful stories of her cruel treatment of her serfs. He made the acquaintance of the leaders of the Slavophile movement — Aksákof, Khomyákof and others, but he did not sympathize very cordially with them. In 1843 he published a narrative poem, entitled 'Parasha by T. L.'. "With that poem" he says in his 'Recollections,' "I entered the arena of literature." Byelinsky, the great critic, reviewed it most favorably in *The Annals of the Fatherland,* and Turgénief declared that the praise caused him more confusion than pleasure; and when Kiriyévesky congratulated him on it he denied being its author. Turgénief, judged by his one small volume of verses, was well-advised when he took to prose exclusively as his literary expression. His first notable work in fiction was the volume of short stories, entitled 'Zapiski Okhótnika' ('A Sportsman's Recollections or Sketches') which were written between 1841 and 1850. With no attempt to preach, they had almost as powerful an effect in stimulating public dissatisfaction with serfdom as Gogol's 'Dead Souls.' The authorities could not find anything to suppress in these artistic subtle delineations of country life on the great estates; but when Turgénief wrote an eloquent eulogy on Gogol and published it in the *Moskóvskaya Vyédomosti* in March 1852, he was subjected to a month's imprisonment and then banished to his estate, where he spent two years — a punishment which he regarded as a blessing in disguise. His literary activity became very prolific. He published 'Dmitri Rudin' (1855); 'A Nobleman's Nest' (1858); 'Fathers and Children' (1862), to mention three of his greatest novels. In each of them he marked an advance in art and won a wider reputation, which was even more generously accorded abroad than in Russia, where his somewhat cynical presentation of "types" was more or less resented. In 1863 he bought a stately house in Baden-Baden, where he lived until 1870. After the Franco-Prussian War he lived mainly in Paris, where he was on terms of intimacy with Madame Viardo. Several of his novels he wrote first in French. In the long list of his other works may be mentioned 'Two Friends' (1853); 'Quiet Life' (1854); 'Faust' (1856); 'Asya' (1858); 'First Love' (1860); 'Hamlet and Don Quixote' (Essays, 1860); 'Visions' (1863); 'The Brigadier' (1866); 'Smoke' (1867); 'A Strange Tale' (1869); 'A Lear of the Steppes' (1870); 'Spring Floods' (1872); 'Virgin Soil' (Or "New" *Nov*); 'Song of Triumphant Love' (1881); 'Poems in Prose' (1882). A fuller bibliography is given in William Lyon Phelps' 'Russian Novelists.' Turgénief was a man of stately presence and courtly manners, a genuine cosmopolitan. He died of cancer of the spine. Besides many translations of individual works there are in English two fairly complete editions of his novels: one by Isabel F. Hapgood; the other by Constance Garnett. A more consummate artist than Tolstoy, his fame and popularity have been in the last few years rather overshadowed by the more vital personality of the Apostle of non-resistance. See FATHERS AND CHILDREN: LEAR OF THE STEPPES, A; SMOKE.

NATHAN HASKELL DOLE.

TURGITE, tėr'jit, a common iron ore much resembling limonite, with which it is usually associated. It is distinguished from that by its red streak, higher specific gravity, 4.14 to 4.68, and by its violent decrepitation when heated. It usually occurs in compact-fibrous, often botryoidal or stalactitic coatings on the surface of limonite. It then possesses a brilliant submetallic lustre on the outer surface and a much duller, satiny lustre on the broken fibrous surfaces. Its color is black or dark brownish-red; hardness 5 to 6. Its most typical American locality is in Salisbury, Conn. It also occurs in an earthy form like red ochre.

TURGOT, tür-gō, **Anne Robert Jacques,** French statesman: b. Paris, 10 May 1727; d. there, 20 March 1781. In 1751 he renounced his intention of entering the Church, and in the end of the following year he was admitted a councillor of the Parliament. While fulfilling the duties of this position he also occupied himself with economical studies, and made himself well acquainted with the physiocratic system of Quesnay. In 1761 he was appointed intendant of Limoges, which post he occupied for 12 years, and was long remembered with gratitude for his wise, salutary and benevolent reforms and regulations. On the accession of Louis XVI in 1774 Turgot was first put at the head of the marine; but a few months later he became comptroller-general of France. He moderated the duties on articles of the first necessity without loss to the revenue; freed commerce from many fetters, and encouraged industry by enlarging the rights of individuals, and abolishing the exclusive privileges of companies and corporations. He

also formed a project for commuting the feudal rights, for rendering salt an article of free merchandise, and for reforming the royal household. His reward for these useful and benevolent views was opposition and ridicule. He was, however, able to carry into effect some very important improvements; but as he endeavored to control the nobility, restrict the clergy, and restrain the license assumed by the officers of the Crown, they all united against him. The result was his dismissal from office in 1776, from which period he lived a retired and studious life until his death.

TURIN, tū'rĭn, or **TORINO,** tō-rē'nō, Italy, capital of the province of the same name, on the Po, 75 miles southwest of Milan. Its position at the junction of several Alpine mountain routes lends it much military importance. It is a large military station, directed toward the defense of the western highways over the Alps. It contains numerous fine squares of *Piazzas*, chief of which is the Piazza Vittorio Emanuele, unsurpassed on the Continent; Piazza Carlo Emanuele II or Carlina; and others, usually embellished by equestrian statues or busts of distinguished men. The Nuovo Giardino Pubblico, along the river, botanical garden, Giardino della Citadella, Giardino Reale and zoological garden are interesting parks. The Renaissance cathedral (1492–98) has a marble façade and contains the tombs of the Dukes of Savoy. Other churches are the Consolata, San Spirito, San Massimo, Gran Madre di Dio, a Moorish synagogue, and a Waldensian church. La Superga is a fine Basilica on an eminence overlooking the town. It is the burial chapel of the House of Savoy. The chief palaces are Palazza Madama, Carignano,— with natural history collections — Palazzo di Città, or town hall — containing a library and monuments — Palazzo Reale, or royal palace, with a royal armory, Palazzo dei Torri, Palazzo del Accademia delle Scienze, with a fine collection of antiques and a picture gallery, etc. The museums and Accademia Albertina delle Belle Arti, the exchange, arsenal, university (1404), theatres, hospitals and numerous schools are the other important edifices. One of the best libraries of Europe is housed in the Biblioteca Nazionale. The Royal Albertine Library of 60,000 volumes and 3,000 manuscripts is also located here, and there is a municipal library of 104,000 volumes. Manufactures are important and consist of silks, jewelry, furniture, pianos, gloves, leather, paper, iron and steel goods, soap, tobacco, machinery, and velvet hats; silk and wine are exported. Turin was the capital of the modern kingdom of Italy until 1865; it was the ancient capital of the Taurini, a native tribe of Celto-Liguarians, and was the seat of government under Charlemagne until 1032. The French captured the town in 1640 and in 1800 annexed it. In 1815 it was restored to the House of Savoy. Pop. 451,994. Consult Borbonese, 'Torino illustrata e descritta' (Turin 1884), and Promis, 'Storia dell antica Torino' (ib. 1871).

TURIN, University of, Italian school founded by Louis of Savoy (1405). Toward the latter part of the 15th century it shared the prosperity of the period. It was reorganized in 1632 and the present building was erected in 1713. The university has faculties of law, medicine and surgery, philosophy and letters, and physical and mathematical sciences. There is an average annual attendance of over 2,000 students.

TURK ISLANDS, British West Indies, a group of small islands lying at the southeastern extremity of the Bahamas, north of Haiti, but forming, with the neighboring Caicos Islands, a dependency of Jamaica. The area is 165½ miles. Grand Turk, the principal member, is seven miles long, but the Caicos Islands are larger. The chief product is salt. Pop. 5,615, of whom 286 are white. Education is free in the government schools, of which there are nine of primary grade, with an enrolment of 1,030, and an average attendance of 794 pupils. The total imports annually amount to about $150,000 and exports somewhat less. There is a cable station at Grand Turk. See CAICOS ISLANDS.

TURKESTAN, toor-kĕs-tăn', Central Asia, the general name given to the region lying between Mongolia, China and Tibet on the east and the Caspian Sea on the west. It is divided by the Mustagh range and a southwestern outrunner of the Tyan-Shan Mountains into East or Chinese Turkestan and West or Russian Turkestan.

EAST TURKESTAN is bounded on the north by Sugaria, on the east by Mongolia and China, on the south by Tibet and India, and on the west by Western or Russian Turkestan. Area, 550,340 square miles. It consists of a desert plateau basin skirted by the Tarim River, and encircled on all sides by mountains — on the north by the Tyan-Shan, on the south by the Kuen-Lun, and on the west by the Pamir highlands. Agriculture is carried on only in the oases and in irrigated districts along the river, where cotton, tobacco and hemp are grown. The chief exports are silver, silks, felts, carpets and cotton. East Turkestan belongs administratively to the Chinese province of Sin Kiang. Pop. 1,200,000.

WEST TURKESTAN in its widest sense includes the entire southwestern portion of Asiatic Russia. It consists of the states of Khiva and Bokhara in the south, the general government of the Steppes in the north, and the general government of Turkestan, or Russian Turkestan proper. The latter reaches from the Chinese Empire to the Caspian Sea, and consists of the districts or provinces of Samarkand, Fergana (with Russian Pamir), Semiryechensk, Syr-Darya, and the Trans-Caspian region. Area, 649,644 square miles; exclusive of Trans-Caspia, 409,414 square miles. The extreme eastern and southeastern parts are mountainous, but the greater portion consists of vast arid steppes traversed by the rivers Amu and Syr Darya which flow into the Aral Sea. Only the irrigated portions along the rivers can be cultivated; they produce wheat and rice in great quantities, besides melons, grapes, fruits and cotton. The nomadic inhabitants of the steppes are engaged in cattle raising. Wheat, raw cotton and cattle products are the principal exports, and trade has been greatly facilitated by the completion of the Trans-Caspian Railroad. The capital of the general government is Tashkent and the pop. about 5,300,000; exclusive of Trans-Caspia, 5,000,000.

TURKEY, a river in northeastern Iowa. It flows southeast and enters the Mississippi in

the southeastern part of Clayton County. The Galena limestone is found in the Turkey River Valley. The river is about 100 miles long.

TURKEY, an American game-bird of the pheasant family and genus *Meleagris,* widely known both wild and domesticated. The common northern wild turkey (*M. gallapavo*) formerly inhabited almost all parts of the United States and southern Canada and southward through the greater part of Mexico; it is now numerous, however, only in thickly wooded mountainous and inaccessible regions. It is a very beautiful bird of trim form and stately mien and the cock is colored with golden bronze hues, marked and varied by the blue and black lustre of the plumage. A peculiar tuft of hair-like feathers is suspended from the breast, and the head and neck are furnished with wattles and erectile structures, which under excitement exhibit varying tints and hues. The wild turkey is a bird of the forests, where it lives in small flocks which enter clearings only to feed. They are eminently terrestrial, being swift of foot, and they scratch on the ground for the nuts, seeds, insects, etc., upon which they feed or pick berries and small fruits from the bushes. When pursued they prefer to run and seek concealment in the underbrush but if forced to fly are strong of wing. At night they roost in the tops of trees and are always keen-sensed and alert. Like most of the pheasants turkeys are more or less polygamous and in the spring the cocks fight viciously for the possession of mates, before whom they show off in the pompous and ludicrous manner so well known in the domesticated bird. A simple nest on the ground, often by the side of a log, is made and lined with dry leaves; in it from one to three females deposit from 10 to 25 eggs, which are dirty white with reddish spots. Only one brood is raised in a season unless accident overtakes the first.

Although formerly so abundant and so tame that the early settlers found the neighboring forests almost as convenient as poultry yards, few persons have now the opportunity of shooting a wild turkey, but any such are events in the life of a sportsman, for success requires both skill and knowledge. The method most in vogue is for the concealed hunter to attract the birds to him by imitating their call upon a turkey whistle and to shoot the wary birds as they appear. This method is most effective when the hen's call is employed to attract the cocks. They are also hunted with dogs or even stalked.

The domesticated turkey is derived from the Mexican variety, examples of which were carried to Europe in the early part of the 16th century; but it is possible that the strain may have been mixed in England with northern birds. The latter were partially domesticated by the Indians and New England settlers. The domesticated turkey has lost the grace, agility and brilliancy of color of its progenitor, but in other respects has been but little modified. In habits it is indeed still a half wild creature. In the four centuries of its domestication it has remained remarkably stable and except in color no distinct varieties have been produced. Of its habits, appearance and merits nothing need be said. The young of the domesticated turkey require especial care for the first five or six weeks of their existence.

The beautiful Central American ocellated turkey (*M. ocellata*) is of rather less size than the common turkey, but more brilliantly colored. This species lacks the tuft of hairy feathers seen on the breast of the other and derives its specific name from the presence of brilliant eye-like spots on the tail-coverts.

F., 'Turkeys: Standard Varieties and Management' (United States Department of Agriculture, Washington, D. C., 1915); McIlhenny, E. A., 'The Wild Turkey and its Hunting' (Garden City 1914); id., 'Turkeys, Waterfowl and Guineas' (Mountain Grove, Mo., 1914); Sandys, 'Upland Game Birds' (New York 1902).

TURKEY, or THE OTTOMAN EMPIRE (MEMALIK I OSMANIE), an empire consisting of territory in the peninsula of Asia Minor and southwestern Asia, and also a portion of southeastern Europe in the vilayets of Adrianople, Chatalja and Constantinople, and in Asia, Arabia, Syria, Palestine, Mesopotamia and Kurdistan (qq.v.). The end of the first Balkan War in November 1913 saw Turkey's European territory considerably curtailed, its former holdings being in part divided between Bulgaria, Greece, Montenegro and Serbia. This loss of territory was inconsiderable compared with that which was ordered by the Paris Peace Conference after Turkish arms had gone down to defeat in October 1918. For these territorial changes see WAR, EUROPEAN — PEACE TREATIES. The Ægean

VILAYETS	Area square miles	Population
Europe:

Islands are in possession of Greece and Italy. Cyprus and Egypt, which until recently were under the suzerainty of the Sultan, are now under the British flag — the former being annexed in November 1914 and the latter made a British Protectorate in January 1915. The total area of Turkey's present dominions may be estimated at about 613,700 square miles with a total population of about 20,975,000. Yemen and Hedjaz became independent states during the war.

At the time Turkey entered the war on the side of the Central Powers in 1914 her area and population were as shown in table on preceding page.

Topography.— Former European Turkey formed a peninsula bordered by the Black and Marmora seas, the Bosporus and Dardanelles on the east and south, on the southwest it was bounded by the Ægean Sea, of which the only important indentation in this region is the Gulf of Saros. Its northwestern boundary is the Maritza River and its northern the frontier of Bulgaria. There are no great elevations in this region. Near the Bosporus Devonian formations are in evidence but away from the coastal hills stretches a plain of comparatively recent formation, the principal part of which is the valley of the Maritza in which there are few points over 600 feet above sea-level.

Asiatic Turkey is bounded on the north by the Black Sea, on the east by Persia, south by Mesopotamia and the Mediterranean and west by the Ægean Sea. The coast line is regular except in the vilayets of Bigha and Brussa, which have numerous indentations and are fringed with thousands of islands. The Taurus and Anti-Taurus ranges extend through Turkey from Persia to the Ægean Sea, and in many places send out short spurs which on the south slope to the plains, but end abruptly on the north.

Hydrography.— The chief river of Turkey in Europe is the Maritza (the ancient Hebrus), which enters the Ægean Sea near Enos. Adrianople is situated on its banks. It was on the bank of this river, near Adrianople, that, in 1364 occurred the battle between the Christians and the Turks, which resulted most disastrously for the Christians. The Kizal-Irmak (Red River), the largest stream in Asia Minor, is about 600 miles long. It flows in a north by east direction into the Black Sea. The Mendere (the ancient Mæander) flows into the Ægean.

Geology and Mineralogy.— The southeastern part of European Turkey belongs geologically to Asia. Devonian rocks are found on both sides of the Bosporus, and the similarities are multiplied by the fossils, the rock layer, the appearance of the river beds, and the nature of the soil and stone. Lava of considerable depth covers a large portion of the plains of Asia Minor. The marks of violent upheaval and of volcanic action abound. The mountains of Turkey are rich in minerals, but mining is yet in a crude condition. Meerschaum is found at Eskisheh, in Asia Minor, and copper, lead, coal, antimony, rock salt, emery, alum, nitre, iron ore and chalk abound in many places. A valuable lithographic stone is quarried near Brussa. A royalty of from 5 to 15 per cent is paid on all minerals which are exported from Turkey.

Climate.— The climate of Turkey in Europe is about the same as that of the countries in Europe which border on the Mediterranean; but radical changes occur frequently. The cold northeast winds which sweep down from the frigid regions of Russia modify greatly the climate of the north and south valleys. In the northern portions of Asiatic Turkey the winters are cold and humid; in the sheltered valleys the climate is comparatively uniform and warm. The rainless season is from April to September but the heavy dews furnish a large amount of moisture The highest peaks of the Taurus Mountains are covered with snow all the year.

Flora and Forests.— On the lowlands of Turkey in Europe, and on the lower slopes of the mountains, are found a variety of evergreen trees, box, myrtle, palms, sycamore and also walnut, almond and carob trees. The grape-vine and the citron flourish on the eastern and southern slopes and in the valleys. The roses from which the celebrated «attar of roses» is distilled grow in abundance on the plain of Adrianople. Many of the flowering plants of Asiatic Turkey belong to the same families as those in European Turkey, but they differ in genera. On the lower slopes of nearly all the ranges are found cedar, cypress and oak trees. On the plains are large groves of mulberry and sycamore, and in the valleys are grape-vines, groves of orange, olive, fig, pomegranate and many nut-bearing trees. Some of the interior plains are almost treeless and a large acreage is used for pasturage. Grasses, sage, wormwood and broom grow on those plains. South of Armenia the grape-vine, lilac and jasmine are features. A species of maize grows wild on many of the warm lowland regions.

The forest laws (recent) are modeled after those of France; but no restrictive laws are enforced, and Turkey is being rapidly deprived of timber.

Fauna.— The principal wild animals of European Turkey are the dog, cat, boar, badger, bear, civet, squirrel, chamois, roe, deer, beaver, mole, hedgehog, wolf, marten, fox, hare and bat. Fish are found in large quantities and in nearly all the waters. Coral and sponge fisheries are extensive. Leeches exist in the marshes. There are over 240 species of birds of which about 100 are songsters. In Asiatic Turkey the striped hyena, lion, bear, jackal, wolf and wild boar are fairly numerous, and the hare, hedgehog, jerboa, leopard, mole and wolf, abound in certain regions. The domestic animals are the horse (the camel is more common), ox, ass, goat and sheep. A famous species of goat is found in Angora (q.v.). The buffalo supplants the ox in many parts of Asiatic Turkey. The bee and the silkworm are raised in many sections, but especially in the southwestern part of Asiatic Turkey.

Soil and Agriculture.— The greater part of the lowland region of Turkey in Asia has a most productive soil, but lack of moisture makes some portions almost a desert. Irrigation has reclaimed certain localities. The chief occupations in all of the Ottoman Empire are agriculture and cattle raising, yet agricultural

methods are most primitive, and only a small portion of the arable land is under cultivation. Agricultural development is retarded by the system of levying tithes on all the produce, and by the internal custom dues which oblige the farmer to pay a fee on all produce exported from one province to another.

The land is held under four different forms of tenure: (1) "Miri," or Crown lands; (2) "Vacouf," or pious foundations; (3) "Mulikaneh," or Crown grants; (4) "Mülk," or freehold property. The Crown lands form the largest portion and are held directly from the Crown. The government grants permission to cultivate an unoccupied tract and in return exacts a certain fee; but continues to exercise the right of seignory over the rented land. If the lessee neglects to cultivate the land for three years in succession, it reverts to the Crown, and again becomes "unoccupied land." The "Vacouf" lands were instituted originally to provide for the maintenance of the religion of the state and for the education of the people. These lands are now mostly in possession of government officials. The "Mulikaneh" lands were granted to the old feudal troops as a reward for military services. The title to such lands is hereditary, and the land is exempt from tax. The freehold lands do not exist to any great extent, but some of the peasants have purchased "Mülk" lands from the government. Two other categories of land are recognized in law — land set aside for community use (*metruké*) and "dead" or unutilized land (*mevat*). The entire body of law in regard to real property is antiquated and in urgent need of revision and codification. A beginning in this direction was made in 1913 and again in 1918, under enactments providing for a general survey and revaluation of all landed property in the empire, together with a readjustment of taxes; for corporations to hold real estate in the name of the corporation; for the mortgaging of property as security for debts; for the suppression of *guedik* (guild) property; and for the extension of the right of inheritance. The farmers produce but little more than is required for their own use, on account of the system of levying tithes on all farm produce and the exportation taxes on all produce sold and exported to other countries, or to different parts of their own country. The system of levying these taxes is burdensome and oppressive, the general practice being to farm it out to contractors.

Agriculture is carried on in a most primitive fashion. The soil is in general very fertile; the principal crops are tobacco, a world-famous product, cereals of all kinds, cotton, figs, nuts, almonds, grapes, olives, all varieties of fruits, coffee, madder, opium and various gums. There are 16,567,775 acres under cultivation as follows: 13,689,474 under cereals; 473,085 acres under fruits and vegetables; 779,982 acres under cotton, flax and other industrial crops; and 1,213,530 acres under vines. Coffee is grown in the Hodeida region; Konia is the principal centre of opium production; while tobacco is fairly widely distributed. There are about 18,000,000 acres under forest. The forest laws are patterned after those of France, but their enforcement is very lax and the country is being denuded rapidly of its timber. Pine, larch, oak, fir and the cedars are the more important timber trees. Mulberry plantations are on the increase and the silk-worm industry is being revived. The product is largely marketed in France. A recent livestock census showed 2,397,348 horned cattle, 163,691 buffaloes and 30,942 pigs in Turkey.

Manufacturing and Other Industries.— The manufactured products are mostly hand made. Although there is an abundance of raw material, manufacturing has declined since about 1850. The carpets for which Turkey was once famous, the woolen goods of Macedonia (now itself lost to the empire) and other products, have in almost all parts of the empire been undersold by the machine products of other countries. A few glass factories and several paper mills have been established. Turned-brass and beaten-copper utensils for household purposes are made by hand. There are a few steam manufactories in Constantinople. The government operates cloth mills at Kara-Mursal and Ismid in which modern machinery has been installed. The chief output has been khaki woolen cloth for the use of the army. There is a woolen yarn-spinning works at Panderma, which employs 140 wage-earners and turns out 2,750,000 pounds of yarn annually. Fishing is an important industry; the fisheries of the Bosporus alone have an annual value of over $1,250,000. The methods of fishing are most primitive. The sponges obtained along the Mediterranean rank with the best in the world. Pearl is obtained from the Persian Gulf and mother-of-pearl from the Red Sea.

Transportation.— The length of railroad line in Asiatic and European Turkey on 1 Nov. 1914 was as follows: In Europe (miles open only): Salonicâ-Monastir, 136 miles; Constantinople-Salonica, 317 miles; Oriental railroads, 593 miles, or a total of 1,046 miles in European Turkey. In Asia: Haidar-Pasha-Angora, 358 miles; Eski-Shehir-Konia, 283 miles; Mudania-Brussa, 25 miles; Smyrna-Cassabra, 165 miles; Alasheir-Afion-Karahissar, 156 miles; Smyrna-Aidin, 320 miles; Konia-Eregli-Persian Gulf, 125 miles; Messina-Adana, 42 miles; Beirût-Damascus-Mzerib, 153 miles; Rayak-Aleppo, 204 miles; Tripoli-Homs, 63 miles; Damascus-Medina, 812 miles; Jaffa-Jerusalem, 54 miles; Haifa-Deraa, 105 miles; making a total of miles open for Asia of 2,865. Territorial changes after the Great War have caused the loss of much of this mileage to Turkey. The Bagdad Railway concession to Germany had for object the extension of the Anatolian line from Konia to Adana, Mosul, Bagdad and Basra, with numerous branches. It has been constructed continuously as far as Kara Bunar in Cilicia. The following sections have also been completed: Dorak to Bagtché on the Adana side of the Taurus Mountains; Radjun via Muslimié to Jerablus on the Euphrates, with branch from Muslimié to Aleppo; Jerablus to El-Abiad in the direction of Nisibin (with a wooden bridge over the Euphrates); Bagdad to Samara; Alexandretta to Toprak Kalé on the Dorak-Bagtché line. The line from Konia to Bagdad will have a total *length of* 1,509 miles, of which 1,117 miles (not continuous) are now in operation. In 1916 Turkey,

as it then was, had 3,720 miles. Before the Great War the Turkish government controlled 1,116 miles. The British military authorities took over the administration of the Bagdad Railway in January 1919. There are 1,814 post offices in the empire, which handle an average of about 22,000,000 letters, 2,000,000 post cards and 14,000,000 samples and printed matter annually. A parcel post system has been introduced. Foreign post offices were abolished in Turkey on 1 Oct. 1914. There are 28,890 miles of telegraph lines with about 50,000 miles of wire and about 11,000 telegraph offices. The volume of business approximates 6,000,000 messages annually.

Commerce.— Commerce as well as agriculture seems to be greatly retarded and its development prevented by the duties on imports and exports and the taxes imposed on the trade between different divisions of the empire. All articles imported into Turkey are taxed 8 per cent ad valorem, except tobacco and salt, which are monopolies. There is an export duty on all produce sent abroad, except cereals, and all produce sent from one division of the country to another pays the 8 per cent. The total trade of Turkey in 1913–14 was $183,048,400 for imports and $97,180,600 for exports. In 1916–17 the imports declined to $98,526,520 and the exports to $58,292,905. The imports in 1913–14 came from the United Kingdom, 20 per cent; Austria-Hungary, 15 per cent; France, 7.7 per cent; Germany, 12 per cent; Russia, 7.5 per cent; Rumania, 10 per cent; Italy, 11 per cent; Egypt, 4 per cent and the United States 2.6 per cent. Greece, Bulgaria and The Netherlands supplied the remainder. The exports were taken by Great Britain, 20 per cent; France, 18 per cent; Austria-Hungary, 11 per cent; and Egypt, the United States and Germany about 4.5 per cent each. In 1916–17 almost 80 per cent of both import and export trade was with Germany and Austria-Hungaria.

Shipping and Navigation.— The shipping and navigation facilities of the Turkish Empire consisted in 1911 of 120 steamers with a total carrying capacity of 66,878 tons; sailing vessels, 963, with a tonnage of 205,641.

Army.—At the beginning of 1914 the new military service law was put into effect by the War Minister, Enver Pasha. Under the terms of this law it was ordained for the first time that every male Ottoman subject was liable to military service and that even where an exoneration tax would be accepted, this did not exempt the individual from military training, but only from a portion of the full term. When the army was mobilized later in the year, the provisions of the law were rigorously enforced, in so far that all males of military age, whether Moslem or Christian, were called into the service. Inasmuch as there were numerous exemptions under previous laws, under which Christians were almost wholly exonerated from service, a very great number of untrained men were called to the colors. These were divided into three classes: (1) Moslem, who were at once placed in training; (2) Christian, few of whom were placed in combatant service, but who were largely employed in transport and auxiliary service, and (3) certain persons, both Moslem and Christian, who were allowed to pay a high exemption tax. This tax was used to defray expenses of mobilization, etc. In February 1917 a law was passed providing for universal military service between the ages of 20 and 45. The term of actual service was placed at two years in the infantry and three in other branches, the remaining years up to 40 being spent in the *Ihtiat*, or reserve. From 40 to 45 the service is continued in the *Mustahfiz*, or territorial army. The tribal, or irregular Kurdish, cavalry was employed in military operations during the Great War. Turkish divisions have normally three line regiments and six to nine field or mountain batteries, each line regiment consisting of three battalions; thus the division comprises nine battalions. The artillery, where armed with quick-firing guns, is organized in four-gun batteries and where armed with older guns, in six-gun batteries. An army corps consists of two or three divisions, a cavalry brigade, three howitzer batteries, engineer battalion, transport battalion and signal company. The peace strength of the army is estimated at about 200,000 men; the war strength is approximately 1,000,000.

In addition to the regular military forces mentioned above there are large forces of gendarmerie, necessitated by the many subject races and turbulent elements within the empire. This force amounts to about 60,000 men, of whom about 16,000 are mounted. It is distributed throughout the empire and during the Great War the bulk of this force performed army duties, being replaced by territorial forces. The Turkish infantry is armed with the 7.65 millimeter Mauser magazine rifle, model of 1890. The artillery possesses about 110 quick fire field and horse batteries of 7.5 centimeter Krupp batteries. The mountain artillery has 22 batteries of the same size Krupps and 27 Schneider quick-fire batteries.

After 1909 the Turkish army was reorganized under direction of a German military mission, whose head was Field Marshal von der Goltz. The mission consisted of about 20 officers. Four years later the scheme was amplified and the mission expanded to 40 officers. Marshal Fiman von Sanders and his suite took charge in January 1914. For the history of the Turkish campaigns see WAR, EUROPEAN.

Navy.— The only ships of real value as naval vessels are the *Torgut Reïs* of 9,876 tons and armed with six 11-inch guns, fitted with engines developing 10,000 horse power and capable of steaming 16 knots; the *Sultan Selim*, battle cruiser, formerly the German *Goeben* (see GOEBEN AND BRESLAU) of 22,640 tons, armed with 10 11-inch guns and 12 six-inch guns, and four torpedo tubes, engines of 70,000 horse power and having a speed of 27 knots; the cruiser *Hamidieh* of 3,800 tons, armed with two six-inch and eight 4.7-inch guns, engines of 12,500 horse power and with a speed of 22 knots. In addition there are about 20 gunboats and vessels, one-half of them being modern, nine destroyers and six torpedo boats, with some transports and a considerable number of auxiliary vessels and motor boats. A submarine flotilla was brought into being during the Great War. Under the terms of the armistice concluded 30 Oct. 1918 all Turkish ships and vessels of war were surrendered on 5 November to the Entente powers. The vessels lay at the Golden Horn, except the *Sultan Selim* (ex-*Goeben*), which was at Stenia, in the Bosporus.

Religion.— Mohammedanism is the officially established and recognized religion, but other forms of worship are tolerated. Among these non-Mohammedan native communities or "Millets" which are recognized by the Turkish government are Latins or Catholics, Orthodox Greeks, Armenians, Armenian Catholics, Chaldean Catholics, Protestants, Nestorians, Syrian Catholics, Syrian Jacobites, Melchites, Jews, Bulgarian Catholics and Maronites. All these may possess their own ecclesiastical rule and their spiritual heads have a high place in the civil community. The sultan as caliph is supreme head of the Moslems. The chief ecclesiastical dignitary is the Sheikh-ul-Islam, but his functions are judicial and legal rather than spiritual. He is a member of the Cabinet.

There is no priesthood in Mohammedan Turkey in the strict sense of the term. The Ulema, however, or persons connected in one way or another with the official ministrations of Islam, form a separate class. The principal charges in connection with mosques, theological schools, etc., are to a large extent hereditary. The number of mosques in the empire as it was in 1914 is computed at 2,120, of which 379 were in Constantinople and many others in territory now torn from the empire. The number of the clergy was 11,600. Connected with the mosques are 1,780 elementary schools, where education is supplied gratis. The temporalities of the Church are controlled by the Ministry of Pious Foundations (*Evkaf*), which has a separate budget of its own. The revenue of the Evkaf is derived chiefly from charges on and reversionary interests in real property which has at one time or another been made the subject of consecration to religious purposes, and which is known as Vakuf. The department of the Sheikh-ul-Islam is not provided for in the budget, but in that of the state. Moslems form 92 per cent of the whole population; Christians about 7 per cent and Jews the remainder.

Education.— Elementary education is nominally obligatory for all children of both sexes. A law of 6 Oct. 1913 provided that children from 7 to 16 should receive primary instruction either in state schools, schools maintained by religious communities, private schools or, subject to certain tests, at home. State schools are under the direct control of the Minister of Public Instruction. Community schools also are inspected by the Ministry. There are several religious foundations which maintain theological seminaries. There are also intermediate or secondary schools for boys from 11 to 16 years of age, and similar institutions for girls were inaugurated in 1918–19. Five such schools for girls in Constantinople have 2,000 pupils. Aleppo has 710 Moslem, 250 Christian, and 30 Jewish, with 19,000, 8,000 and 2,000 pupils respectively. In all 36,230 schools were enumerated in 1918 with 1,331,200 pupils. There are training schools for teachers but the standard is low. French, English, German and American missionaries maintain sectarian schools. A university was founded at Constantinople in 1900. It was reorganized in 1918. There are five faculties, arts, theology, law, medicine and science. The faculty of medicine and the Military Medical School occupy a modern building at Scutari. Other schools of higher learning are the Imperial Art School, the Greek Great National School, with 400 students, and the Greek Theological Seminary with an average of 80 students.

Archæology.— The modern explorers, excavators and decipherers, or translators, have given us a new world, a large portion of which is below the surface of the territory occupied by the Ottoman Empire, chiefly in Babylon, Asia Minor, Palestine, Egypt, Assyria and Arabia. The land of Babylon and Nineveh, of Assyria and Khorsabad would naturally be fruitful in records of the past. The number of cuneiform documents found in Macedonia alone are of great value. One of the causes which have contributed to the recent activity in searching for archæological remains is the desire to secure corroborative testimony in favor of the Bible. Such reasons greatly influenced some of the American missionary societies to begin investigations. The University of Pennsylvania sent out an expedition which discovered, in the vicinity of Nuffar, 2,000 cuneiform tablets, many of which were in existence 2,800 years before the birth of Christ. Dr. Hilprecht was appointed to supervise the editing and classifying of the results of the expedition. The collection contains many inscribed bricks, clay stamps for bricks, marble vases, sacrificial vessels, door sockets, enameled and plain vases, seals and seal cylinders, gold and silver ornaments, clay sarcophagi, stone, iron and bronze articles, bas-reliefs, intaglios, human skulls and numerous other articles. The American Archæological Institute explored the territory near Asso (present Behram) in the years 1881-82. The excavations brought to light buried fortifications of successive periods, baths, theatres, temples which were of the archaic Doric order and down to and within the Christian era, porticos, private dwellings, a gymnasium, a Greek bridge and a highly ornamented group of tombs. Other exploring expeditions have been sent to Turkey by the French, English and Germans, and the Turkish government has given the matter considerable attention. In an article on the Turkish excavations by Americans, written by James B. Fox, he says: "The dreary solitudes that long brooded over those buried civilizations have begun to disappear before the labors of dauntless and indefatigable explorers, and a literature, almost overwhelming in extent, graven in clay and stone, transports us back to the very cradle of the race. They reveal a perfection of art, a marvelousness of correspondence, a development of civilization in those primeval days that excite the wonder and admiration of our more enlightened age. Schools and libraries must have existed everywhere; clay books were stored in the cities; letters of every description were exchanged on every subject; and, judging from the tablets of Zel-el-Amarna, Canaan was a centre of correspondence, even before the age of the Exodus. The objection of the 'higher critics' that Moses could not have written the Pentateuch, because the art of writing was unknown in his day, falls hopelessly to the ground."

The whole country, especially Syria, Palestine and Babylon, contains vast archæological treasures. Specimens of Byzantine architecture still exist in a good state of preservation. The statues found among the ruins of ancient Nineveh, and preserved in the British Museum, are remarkable monuments. The half-tamed

Turk had wandered for centuries over the plains near the Tigris without ever dreaming that he was crossing the place of sepulchre of a once gorgeous city, until Sir Henry Layard (q.v.) and other English explorers began the excavations which restored Nineveh to the world.

The Turkish government has, since 1884, opposed the removal of objects of antiquity from the country, and no excavations may be made without a firman. The government has a valuable collection of archæological specimens at the museum of Tchinli Kiosk. The splendid archaic frieze of the Doric temple in Assos is not in one place, but portions are in America, Paris and Constantinople. Facsimiles of some of the famous statuary found in Nineveh (originals in England) are in museums in New York and other places. See ASSYRIA; ASSYRIOLOGY; BABYLON; CANAAN; BIBLICAL ARCHÆOLOGY; NINEVEH; PALESTINE; TEL-EL-AMARNA, etc.

Finance.— The public revenue of Turkey comes from the following sources: direct taxation, tithes, verghis (land and property tax), temettu (income tax), for exemptions from military service, aghnams (tax on sheep, cattle, etc.), and other sources; indirect taxation, various customs (salt, tobacco, spirits, stamps, fisheries, silk and other sources), administrative and military departments, share in tobacco Régie profits, tribute revenues and other sources. The largest portions of the expenditure are for debt charges and for military purposes. No regular budget existed before the restoration of the Constitution in 1908. Since that year there have been voted or enacted by the executive a budget and finances for every year. The revenue in 1918–19 was £T33,965,698 ($152,845,641) and the expenditure £T51,762,761 ($232,932,424). The chief items of expenditure were: finances, $46,778,040; post office, $5,350,-414; police, $11,541,406; justice, $4,806,634; education, $4,826,416; commerce, $7,123,059; army, $27,198,454; navy, $7,668,256. For the civil and religious administrations 21 per cent of the general expenditures is allotted, while ordinarily 28 per cent is reserved for the military establishment. Unable to meet its liabilities the Ottoman government made an arrangement with its creditors, confirmed by the *Iradé*, of 8/20 Dec. 1881, supplemented and modified by the *Iradé* of 1 Sept. 1903. A council of administration was appointed, to which were handed over for distribution among the bondholders the funds derived from the excise duties and other funds. On 31 Aug. 1918 the total debt was placed at £T454,649,590 ($2,045,923,155) of which £T149,475,754 ($677,-640,893) is external debt.

Money.—A charter for a new national bank, to be known as the Ottoman National Credit Bank (*Osmanli Itibar milli Bancassi*) was issued by the government in January 1917. Its capital is $18,000,000 (£T4,000,000). With the expiration of the privileges of the Imperial Ottoman Bank in 1925, the new bank becomes the state bank with the right to note issue. The Imperial Ottoman Bank in 1910 had a capital of $45,000,000, a note circulation of £T941,250 ($4,235,625) and cash on hand to the amount of £T3,568,834 ($16,140,753). The note issue of this bank consisted up to 1914 of notes of £T5 and upward ($22.50), secured by a gold reserve of not less than 33 per cent of the face of the issue. During the War 1914–18 there were five emissions of paper currency secured by German treasury bills. The total of these was about $383,000,000. Currency reform was inaugurated on 17 April 1916. A gold standard with the piastre as the unit is to be general all over Turkey. The piastre equals 40 para. Piastre, half-piastre, quarter-piastre and eight-piastre pieces are of nickel. Two, 5, 10 and 20-piastre pieces are of silver, 25, 50, 100, 250 and 500 piastre pieces are of gold. The gold 100-piastre piece weighs 7.216 grammes, .916 fine, or has 6.6147 grammes of pure gold. It is equal to £T1 or $4.50 in currency of the United States.

Weights and Measures.— The *Oke* of 400 drams is equivalent to 2.8326 pounds avoirdupois; the *kileh* = 0.9120 imperial bushel; 44 *Okes* = 1 Kintal or 125 pounds; 39.44 *Okes* = 112 lbs.; 180 *Okes* = 1 *cheke* or 511.380 pounds; *Endazé* (cloth measure) = 27 inches; one *arshin* (land measure) = 30 inches; one *donum* (land measure) = 1,098.765 square yards. Since 1889 the metric system is obligatory for cereals; metric weights were decreed obligatory in 1892, but the decree does not appear to have been enforced. On 1 March 1917 Turkey introduced the Gregorian calendar and it is now used side by side with the Mohammedan or Hegira calendar.

Government.— The government of Turkey is an absolute monarchy and the sultan is the ruler. The succession to the throne is hereditary. It is now and since 1617 has been vested in the family of Othman (or Osman), in the person of its oldest living male member. The sultan is, therefore, succeeded by his oldest son, provided there are no living uncles nor cousins who are older in the Othman family. The oldest son takes the throne without regard to his mother, provided he sprang from the harem. The harem is a permanent institution of the empire, and all children born in the harem, no matter who their mothers are, whether free women or slaves, are legitimate and of equal lineage. It has been the rule and custom of the sultans of Turkey for many centuries not to contract regular marriages, but to maintain the harem. The inmates of the harem are women who are brought to it by purchase or who come to it by their free will. The greater part of them have heretofore come from places outside of the empire, the majority having come from Circassia. The sultan selects a certain number, generally seven, to be "Ladies of the Palace," who are called "Kadyn." The rest are called "Odalik," as they remain under the "Kadyn" as servants. There is a superintendent of the harem, an aged woman of the palace, who bears the title of "Haznadar-Kadyn."

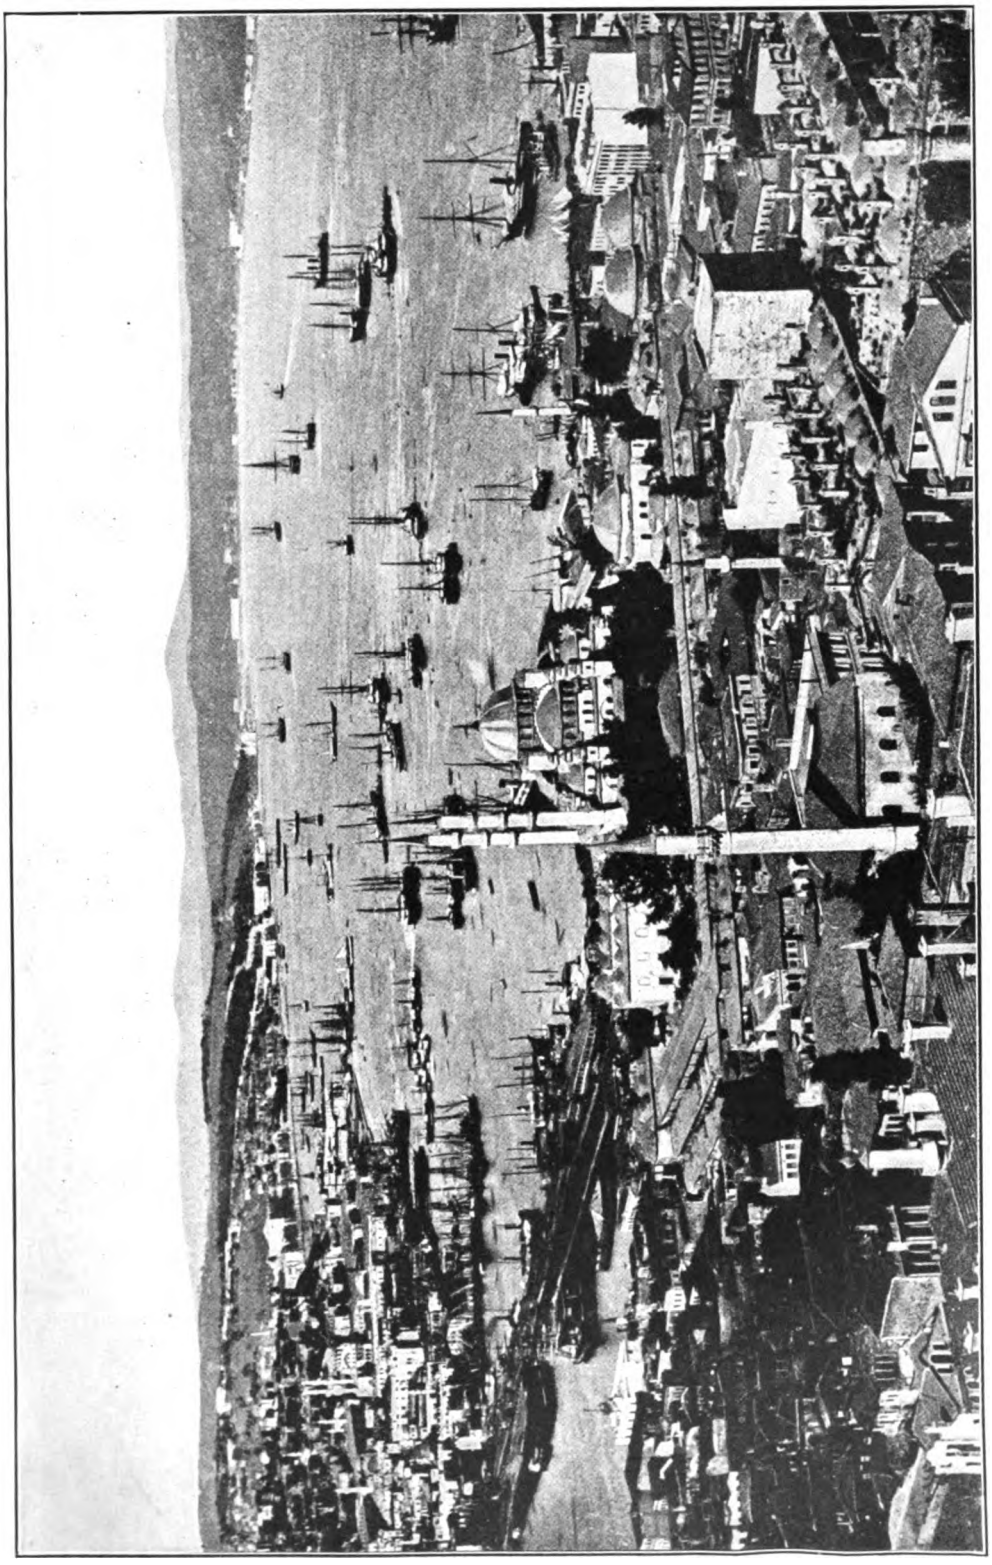
Constitutions after the model of West European states were drawn up at various periods by successive Ottoman governments, the first by Sultan Abdul Medjid was proclaimed 3 Nov. 1839, and the most recent in a decree of Abdul-Hamid II in November 1876. The latter provided for the security of personal liberty and property; for an irremovable judiciary; torture was abolished; the freedom of the press conceded, and equality before the law of all Otto-

man subjects was proclaimed. Islam was declared to be the state religion, but freedom of worship was secured to all creeds, and all persons, irrespective of their creed, were declared eligible to public office. Under this constitution the legislature should consist of two houses, a Chamber of Deputies and a Senate. Senators were to be appointed by the sultan, from among those who had deserved well of the state and should be at least 40 years of age. Every 600 electors were to select one electoral delegate and the latter were to choose one deputy for every 6,000 electors. Electors must be Ottoman citizens of at least 25 years of age and electoral delegates must be at least 30 years of age. In 1878 this constitution became a dead letter and the reign of Abdul-Hamid II was a more complete autocracy than perhaps any of his predecessors. In 1908 the prevailing discontent, which also developed in the army, caused by decades of corruption and misgovernment, compelled the sultan to issue a decree for the convocation of a new Parliament, and on 23 July 1908 constitutional government was restored in Turkey. The constitution in force is theoretically that of 1876, but it has been modified in some respects since 1908. For administrative purposes the empire is divided into vilayets, or governments, these subdivided into sanjaks, or minor provinces, these into smaller divisions known as kazas. At the head of each vilayet is a governor-general, or vali, representing the sultan, and assisted by a provincial council. Over the minor divisions are local authorities (mutesarrifs, kaimmakams, mudirs, etc.), subject to the governor-general. Political reasons since 1908 have led to frequent modification of the vilayet system. Thus several of the sanjaks are governed directly by mutesarrifs reporting direct to the Minister of the Interior. These are known as independent sanjaks and are in every case detached from the vilayet to which they hitherto belonged.

In 1913 a new law on vilayets was promulgated. Its ostensible purpose is to decentralize authority and a bill of 1918 provided for the creation of three new sanjaks in Mesopotamia, to be set up in March 1919. In 1919 Mesopotamia was being administered by the British.

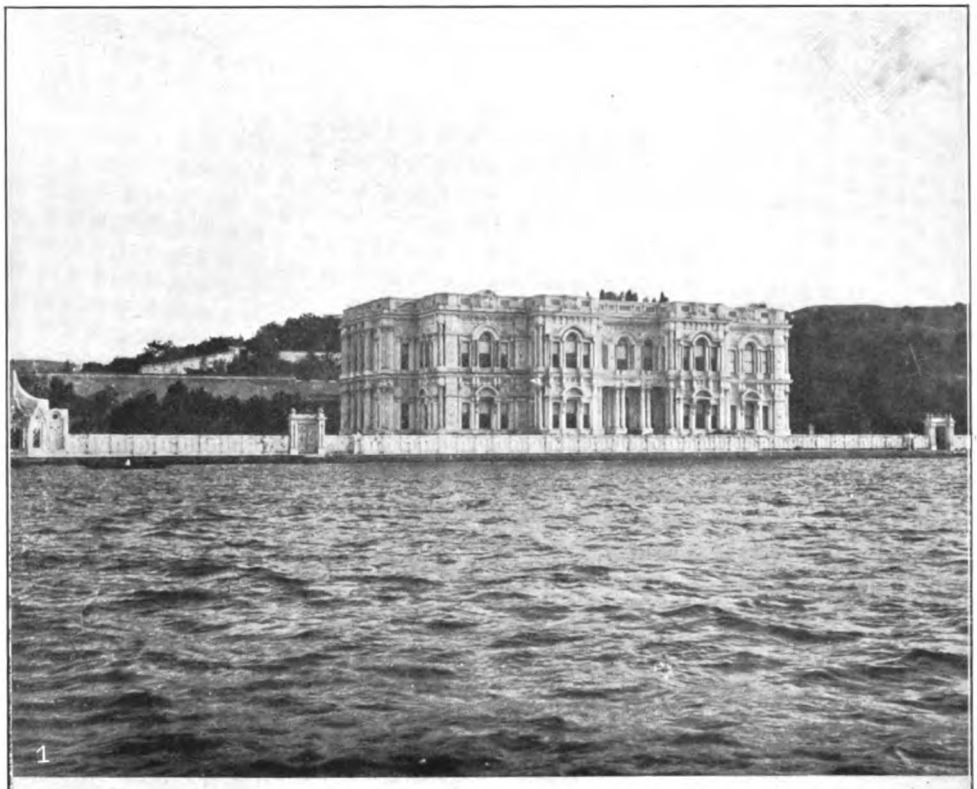
History.— The origin of the Turks, like that of the Arabs and almost all the Eastern nations, is enveloped in darkness. It has been sought in the Tatars of the Caucasus and among the ancient Parthians (the conquerors of Persia); some ethnographers claim the Turks as descendants of the Scythians, or roving Tatars, who possessed the country between Sarmatia and the Tanais, and who, after overrunning all Asia, conquered Turkestan, from which they received the appellation of Turks. The Ottoman people at the present day call themselves Osmanlis, from a Turkish chieftain named Osman (or Othman), who established himself at Brussa in the 14th century. In the Turkish language the word "Turk" means a rustic or clown, and the Turks consequently never apply that word to themselves, but reserve it for the Turcomans and other tribes of central Asia.

The language of the Turks shows they are near of kin to those who spoke the Ural-Altaic or Turanian languages, which were in use from the western frontier of China to the Caspian Sea. There are different dialects, the harsh one of the east and the soft and more melodious one of the west, but many of the words, phrases and grammatical forms are similar. A portion at least of the present Turkish race are descendants of a people who once inhabited the territory west of Lake Baikal. The claim is made that while living near the shores of that lake Christian missionaries visited them, and in support of this claim is the fact that their ancient alphabet had 14 letters based on the Syriac alphabet. The name "Turks" given to the mighty hordes who dwelt on the steppes of northern Asia, at the foot of the Altai Mountains, and beyond Persia, is first mentioned in our history about the middle of the 6th century. They were an aggressive people, seeking existence in lands where others had found sustenance. At the present day the name of Turk or Tatar generally denotes a Moslem speaking a Turkish language, and Mongol a Buddhist speaking a Mongol language. But in earlier centuries it is not so easy to draw that distinction. Timur (Tamerlane) has been described both as a Turk and a Mongol; he came of a Turkish-speaking stock, and his descendants founded the "Mogul" Empire in India, a name which appears to be a variant of "Mongol." The only certain distinction between the Turks and their kindred tribes is linguistic, but in nearly all cases the Turkish-speaking stocks have shown themselves warlike and mobile to a remarkable degree, and where these qualities are found among non-Turkish-speaking tribes — as among the forbears of the Magyars — an admixture of Turkish blood may be suspected. It has always been a puzzle to historians how a race of people which had never before been politically conspicuous in the world should suddenly have exhibited such a marvelous power of conquest. Nor could one have expected the rise of a race of world conquerors from the multitude of barbarians who were ever roving to and fro in the vast sandy desert of Arabia, where they preyed upon one another, marking history with but few traces of their existence. But the Turks, starting as an obscure tribe from the confines of China, have touched Vienna, Algiers, Arabia, Egypt and India; while the Arabs under Mohammed and his successors not only produced and spread a new religion, but extended in less than a century throughout Arabia, Syria and Egypt, along the coast of Mauretania far into the interior of Africa, and included within their embrace Spain and part of Gaul. Eastward, Persia and Scinde had been subdued and Transoxiana invaded by the Arabs. Translations made in recent years from Chinese histories reveal the existence, over 1,000 years B.C., of warlike nomads called Hiung-nu (Huns), a generic title applied to various barbarous tribes whose original haunts were the plains of central Asia, from the Oxus to the Arctic Circle and from the borders of China to the Caspian Sea. They lived on horseback and were trained to handle bows and arrows from childhood. From these records we can trace the Turks as a branch of the Hiung-nu as far back as the middle of the 5th century of our era. One of the clans — the Asena — settled near the modern town of Shan-tan, in the province of Kan-su. In their vicinity was a hill called from its shape Dürkö, or Tü-chüch, the



Constantinople and the Bosporus

TURKEY



1 The Palace of a Turkish Governor-General

2 Boating on one of the Rivers of Turkey

«helmet.» This is said to have been the origin of the name which has since been so widely applied and become so famous in history. About the middle of the 6th century we find the Chinese calling these people the «Tu-kiue» and attributing to them an astonishing degree of progress. Within a few years they became a world power which had relations with China and Byzantium. In about the year 800 they secured possession of a part of the territory now called Armenia, and they named the place Turkomania. They were that branch of the Turk family which learned the Mohammedan religion from the Saracens and, later, founded the Ottoman dominion in Europe. Turks and Saracens first came together early in the 8th century, when the caliph, or successor of the Prophet, ruled as temporal and spiritual chief over the Mohammedan world. As soon as the Saracens began to conquer and convert the Turks, the latter began to play an important part in history. Under the caliphs they appear as slaves, as subjects, as mercenaries, as practical masters, as avowed sovereigns and, finally, claiming for themselves the powers of the caliphate. In process of time the chiefs of this barbarous soldiery arrogated to themselves the most important offices in the state, leaving to their sovereign only a nominal authority. Harassed by civil disorder and sectarian violence, the caliphs were unable to check the usurpations of those who, in their names, ruled the provinces of the empire, and whose ambition it was to become the founders of separate and independent dynasties. Thus one province after another was lost, and in the end Baghdad fell into the hands of the Mogul Hologu. From the 11th to the 13th centuries the Turkish dynasty of the Seljuks (q.v.) ruled over a large part of Asia. Later this empire was divided on account of internal dissensions, and during the 13th century the Mongols became virtually the owners. It was in the course of the struggles between Seljuks and Mongols that the name Ottoman Turks first appeared. Othman was the son of Ortogrul and grandson of a Turkish emir who, early in the 13th century, and on the approach of the Mogul Ghengiz Khan, left his home in Khorassan in search of some safer settlement in Asia Minor. On the march he perished in the Euphrates, but Ortogrul obtained from the Seljuk sultan of Iconium settlements for his followers in the ancient province of Phrygia. His son, Othman, extended his possessions chiefly at the expense of the Greek emperor, and in 1299, on the death of his patron, the ruler of Iconium, assumed the title of sultan. Thus began the Ottoman Empire; a succession of 10 great princes of the dynasty widely extended their territories and raised their military power to the first rank in Europe.

In 1328 the seat of the monarchy was fixed at Brussa, under the shadow of Mount Olympus, and Asia Minor was conquered to the Hellespont. The history of Turkey proper begins with the reign of Othman; he was bold and brave, loyal to friends, cruel to foes and possessed the vices of the conqueror and the virtues of the leader. His immediate successor was his son Orkhan, who assumed command of the armies at the death of his father in 1326. He organized the Janissaries, a body of paid infantry, highly trained and fearless of foe or danger. By marriage he formed an alliance with the Greek emperor and also secured the diplomatic friendship of the Genoese, who were then among the commercial rivals of the Mediterranean. Solyman I invaded Europe in 1355 and Amurath I took Adrianople in 1360 and made it his capital. For many years the waves of Moslem invasion rolled over European battlefields. At times the Moslem armies seemed destined to conqueror the world; Macedonia, Albania and Serbia fell before them. Christian forces flocked together to stem the flood, from Hungary, Italy and the upper Danube; but the Turks defeated the combined armies at Kossovo, 15 June 1389. Sultan Murad was killed the same day; his successor, Bajazet I (q.v.), who was surnamed Yilderim (thunderbolt), had a sanguinary and unsuccessful reign. He began by attacking and taking the dominion of his father-in-law, the Prince of Phrygia. He next suffered a defeat in Europe at the hands of Stephen, sovereign of Moldavia, after which he was suddenly called to suppress Caraman Oghly, a petty Asiatic ruler, whom he speedily crushed, besides taking several provinces in Armenia. Returning to Europe, Bajazet captured some towns on the Danube and nearly the whole of Wallachia. King Sigismund of Hungary called upon the princes of Christendom to repel the Turk. He received a confederate army of some 100,000 Christians under his command; they were defeated by Bajazet with 60,000 men. The Empire of the East, almost reduced to the city of Constantinople, lay invitingly open to Turkish attack. John, son of Andronicus, sought the aid of the sultan against his uncle, Manuel, promising to cede the city on condition that he be allowed to retain the sovereignty over what the Greeks still possessed in the Morea. Bajazet sent him 10,000 Turks, who ravaged the country round the city and compelled Manuel to hand the empty title of emperor to John. Bajazet's schemes of conquest were suddenly arrested by a call to defend his own territory against the redoubtable Tamerlane, who with his Tatar hordes conquered with remarkable rapidity Persia, Mesopotamia, Asiatic Sarmatia and Syria, and forced the gates of Baghdad. The sultan hastily collected a large army and encountered Tamerlane on the plains of Angora (Ancyra) on 28 July 1402. In a fierce battle the Turks, outnumbered, were defeated and Bajazet was taken prisoner. He died the following year of grief and humiliation, in the train of his conqueror. Tamerlane reinstated all the Mohammedan princes who had been dethroned by Bajazet and returned to Samarcand without retaining any of his conquests. An interregnum followed from 1403 to 1413 under Solyman and Musa, two worthless sons of Bajazet. Neither is included in the Turkish roll of sultans. Both were killed in civil strife and the throne fell to their youngest brother, Mohammed I, who reunited the empire, reigned with moderation and justice for eight years and restored much of the national glory lost by his father. During his reign the Grand Vizier Ibrahim organized a Turkish navy, which was destroyed by the Venetians. Murad II (reigned 1421–51) captured Thessalonica (1429), besieged Belgrade in 1435 (on which

occasion artillery was first used against the Turks), defeated a confederation of European princes under King Ladislas of Hungary at Varna, 10 Nov. 1444, and finally defeated the Hungarians under Huniades in 1448. His reign was troubled with conspiracies and pretenders, besides suffering discomfitures at the hands of Scanderberg (q.v.). In 1451 Mohammed II (q.v.) became sultan, one of the most perfidious and sanguinary rulers that history exposes to the execration of posterity. The outstanding event of his long reign (30 years) is the capture of Constantinople (1453), though his whole life may be described as one long campaign, in the course of which he conquered two empires, 12 kingdoms and nearly 300 towns. What he accomplished as a conqueror for the advancement of the Ottoman Empire caused the Turks to regard him as the greatest of their sultans, and in their eyes the glory of his conquests atones for his many vices. He made Constantinople the capital of the empire. He attacked and conquered successively the Morea, Serbia, Bosnia and Albania; from the Venetians he took Lemnos and Negropont; from the Genoese, Caffa; he made the Crimea a dependency of Turkey in 1475, while Otranto in southern Italy belonged to Turkey when Mohammed died, though it was soon reconquered. Greece fell under the Turkish yoke; the empire of Trebizond was conquered in 1461. The island of Rhodes, defended by the Knights of Rhodes, held out against the Turk; the mountain district of Montenegro, in a ceaseless warfare of over 400 years, withstood the Turkish might. The Ottomans were now brought into the neighborhood of Poland, Lithuania and Russia. Greeks, Slavs and Albanians came under Turkish dominion, overcome by the arms of their own children, for the Janissaries, which formed the main strength of the Ottoman armies, were recruited from kidnapped children of the conquered nations. The conquests of Mohammed gave the Ottoman Empire in Europe nearly the same extent it had up to 1878, when the Berlin Congress began the dismemberment of the empire.

The next sultan, Bajazet II, who reigned from 1481 to 1512, was neither a man of war nor a genius like his father. His wars were confined to winning a few points from the Venetians and making raids into Hungary and other Christian lands to the north, committing unspeakable atrocities which provoked retaliation on the part of the Christians. Under Selim I wars of conquest were waged against Mohammedan enemies. He drove the Persians to the valley of the Euphrates and the Tigris. In 1517 he added Palestine, Syria and Egypt to his empire and took over the spiritual authority of the caliphate from a fugitive line of caliphs settled in Egypt. From that time the sultans have combined in their persons the dual rôle of emperor and spiritual head of the Moslem world. Selim outdid his predecessors in systematic bloodthirstiness. When he proposed to massacre all the Christians in his realm and to abolish the practice of the Christian religion, he was sternly opposed and turned from his project by the Mufti Djemali, an honest expounder of his own law and a righteous man. Remembering the humiliating defeat of his grandfather by the Knights of Rhodes, Selim made vast preparations to renew the campaign, when death cut him down, 22 Sept. 1520. His son, Suleiman (or Solyman) the Magnificent, succeeded and reigned 46 years, the most glorious period, according to historians, of the Ottoman dynasty. Allowing for some of those occasional crimes which seem inseparable from every Eastern despotism, Suleiman may be regarded as a good ruler according to his light. He took Rhodes (1522) from the Knights, who withdrew to Malta and became the Knights of Malta. He took Belgrade in 1521 and on the field of Mohacs (1526) subdued half of Hungary. The Turkish armies were the terror of the world and the «Conquering Turk» was a mighty power by land and sea. The north and south coasts of the Mediterranean had been conquered or laid waste; many of the countries of Europe had been conquered in whole or in part and all the rulers trembled. Germany was threatened, but the walls of Vienna (1529) checked the advance of Suleiman's army. The Christian nations suspended for a time their dissensions to marshal their forces against the Turks. The Ottoman Empire seemed strong, almost invincible, but its weakness lay in internal dissensions, for the conquered nations, although subdued, were perennially rebellious. Having settled affairs in Hungary and Wallachia by treaties, Suleiman turned his attention to Persia, where, after some initial defeats, he found himself landed in a war that extended over a period of 20 years. During that time the sultan took large tracts of Armenia and Mesopotamia, together with the strongholds of Van, Mosul and Baghdad. The Turkish navy swept the Mediterranean, the Red Sea and the remote waters of the Indian Ocean. A one-time corsair, Barbarossa, was appointed Capitan-Pasha of the fleet. This celebrated warrior captured Algiers and installed his brother as sovereign; he next defeated the galleys of the Genoese and devastated their coast. Turning to the Italian coast, he took several towns in Calabria, terrorized Naples and even Rome, and then sailed for Africa and made himself master of Tunis. Charles V formed an alliance with several Christian princes and set out for the African coast at the head of a powerful fleet to try conclusions with Barbarossa, who was severely defeated. Tunis was devastated as mercilessly as the Turks themselves could have done it. The Emperor Charles then laid siege to Algiers, lost great numbers of his troops by disease and 140 vessels in a tremendous storm off the Barbary coast. Suleiman now turned his whole naval force under Barbarossa against the Venetian Republic. After ravaging the Archipelago and capturing many of the islands, Barbarossa encountered the combined fleets of Spain, Italy and Venice off Previsa. In the battle that ensued the Turkish admiral gained a decisive victory and Venice sued for peace. From the death of Suleiman I in 1566 the power of Turkey began to decline; the race of rulers degenerated as a whole, not even retaining the military courage and daring of their predecessors. From 1300 to 1566 Turkey was the first military power in Europe. Under Selim II, son of Suleiman, the Turks were first brought into armed conflict with the Russians, thus inaugurating an implacable antagonism that extended down to the 20th cen-

tury. In August 1571 the Turks captured Cyprus from the Venetians, but two months later a maritime league of Austrians, Spaniards, Venetians and the Knights of Malta crushed the Turkish fleet in the battle of Lepanto (q.v.) and temporarily extinguished the fear of an extension of Mohammedan rule in the West.

From Murad III (reigned 1574–95) there follows for 300 years a train of 22 sultans of whom none can be described as noteworthy — until the accession, in 1876, of Abdul Hamid II. Murad III began with having his five young brothers murdered. He raised a cook to the position of Grand Vizier, fought a moderately successful war with Persia and hastened his death by intemperance and debauchery. Mohammed III (1595–1603) went even further than his father in causing his own 19 brothers to be strangled in his presence. He gained some military successes in the Balkans over the Archduke Maximilian and was himself carried off by the great plague in Constantinople a few months after he had put to death his eldest son, Mahmoud, a public favorite. Achmet I (1603–17) encountered revolutions and plague and was defeated by the Persians. Mustapha I (1617) emerged from long captivity to ascend the throne, proved his utter incapacity and was incarcerated in a tower four months later. Othman II succeeded at the age of 14. He introduced the death penalty for drinking wine and made an attempt to conquer Poland, which failed. A revolt of the Janissaries released Mustapha from the tower and replaced him on the throne, while Othman became a prisoner and was strangled in his cell after a brief reign of four years (1622). Within little over a year Mustapha was sent back to his prison as a lunatic. During that short reign the country fell into anarchy and desolation; revolutions in Asia Minor and defeats by the Persians made a new ruler imperative. Murad IV (1623–40) was 13 years old when he stepped into his heritage and quickly gave evidence of a resolute and tyrannical disposition. Insurrections and disasters marked his reign; the Lebanon tribes revolted; the Tatars of the Crimea rose in arms, cut up a Turkish force and ravaged the Black Sea and Bosporus shores; the Persians overran Turkish territory; the treasury at home was empty and the people starving; the soldiers mutinied in the capital and murdered the Grand Vizier; death reaped a bloody harvest throughout the country for months before order was restored. Murad led an army against Persia, reconquered Baghdad and butchered some 25,000 persons of both sexes and all ages (1638). The sultan drank himself to death and was succeeded by his brother Ibrahim (1640–48), the sole surviving male representative of the house of Othman. The new sultan at once plunged into ferocious debauchery. He ordered wholesale executions and was finally strangled after a disgraceful reign of nine years. Mohammed IV (1648–87) was seven years old on his accession. The early part of his reign was marked by all the disorders of a state without a head. Six viziers were deposed or strangled in a few years; the Janissaries and other troops murdered each other wholesale; the Turkish fleet was defeated several times by the Venetians, who took Lemnos and Tenedos, but soon lost those islands again. The pasha of Aleppo broke out in rebellion and was crushed; disturbances in Wallachia led to a great European campaign in which the Turks were opposed by Germans, Austrians, Poles and Hungarians. In July 1664 it seemed that the road to Vienna lay open to the Osmanlis, when the allies inflicted a severe defeat on the river Raab. The city of Candia, in Crete, was again vigorously attacked by the Turks, who had besieged or blockaded the place for nearly 20 years. It now occupied another two years' conflict to compel the Venetians to surrender, 6 Sept. 1669, and the island was added to Turkey. The war against Poland, conducted by the sultan in person, was at first a success for the Turks, who received Podolia and the Ukraine in addition to an annual tribute. In the second stage the tables were turned by the gallant Sobieski. For about 30 years the master minds directing the political and military destinies of Turkey were the Grand Viziers Mehemet and Achmet Kiöprili, respectively, father and son. On the death of the latter in 1678, his brother-in-law, Kara Mustapha, became Grand Vizier — a totally different character from his two brilliant predecessors. His one ambition was the conquest of Vienna, which plan he proceeded to put into execution with an army of about 300,000 men composed of Hungarians (then in revolt against the emperor of Germany), Turks, Tatars, Moldavians and Wallachians. Kara Mustapha reached Vienna with but little opposition and laid siege to the city in the middle of July 1683. The Duke of Lorraine threw 10,000 men into the city just before the arrival of the Turks. The defense made a gallant stand under Count Rüdiger von Stahremberg until the arrival of Sobieski (who was now king of Poland), with Polish, Saxon and Bavarian contingents numbering altogether some 70,000. With this army he attacked the Turks, and, aided by the Duke of Lorraine, fought a sanguinary engagement (12 Sept. 1683) lasting throughout the day. The Turkish host was routed with enormous loss and its camp given over to pillage. For his failure Kara Mustapha was officially doomed at Belgrade to strangulation; his severed head was carried to Constantinople and exhibited in public. The signal defeat of the Turks before Vienna was joyfully hailed throughout Christendom as presaging the downfall of the Mohammedan power in Europe. The empire was attacked on all side. The Venetian Republic declared war and captured several Greek cities from the Turks; Sobieski scattered the Turkish forces and reduced Slavonia and Transylvania. The sultan's troops, overwhelmed with defeat and disaster, revolted against the government. Mohammed lost his throne and was shut up in the same prison from which his brother Suleiman was now released (1687) and girt with the sword of Othman. Suleiman II was 46 years old and had passed the greater part of his life in confinement. A fresh outbreak of the turbulent Janissaries carried riot and murder through Constantinople. They attacked the Grand Vizier's palace, killed that dignitary and murdered the inmates of his harem, whose mutilated bodies were dragged through the streets. The Austrians and their allies harassed the Turks in Hungary, Bosnia and Serbia, retaking Erlau, Gradiska and Belgrade, while the Venetians conquered sections of Dalmatia,

Before the end of Suleiman's second year the Turks had lost all their conquests north of the Danube excepting Temesvar and Gross Wardein. Kiöprili-Lade Mustapha, a son of Mehemet Kiöprili, was appointed Grand Vizier. He restored order and confidence, abolished abuses, administered even-handed justice and enforced religious toleration. He led a successful campaign against Belgrade and defeated the Germans near Essek in 1689–90. Suleiman died in 1691, having reigned barely four years. His brother, Achmet II (1691–95), was an incapable weakling. Kiöprili fell in battle with the Austrians and his army was routed. Famine and pestilence fell upon Turkey; the imbecile ruler died and was followed by a worthier monarch, Mustapha II (1695–1703), who announced that he would himself begin the Holy War against the "unclean Christians." At the outset his Danube campaign proved successful but he came to grief at the battle of Zenta, in Hungary, on 11 Sept. 1697, when the Austrians under Prince Eugene attacked the Turkish army as it was crossing a temporary bridge over the Theiss (Tisza) and, the cavalry being already across, cut it in two and completely routed the infantry, driving them into the river. The prince lost only 500 against the Turkish losses of 30,000. About this time the young Tsar Peter (the Great) of Muscovy sought to open a permanent (ice-free) water communication with the West, with civilized countries, through the Baltic or the Black Sea. But the first belonged to Sweden and the second to the Turks, while the Caspian was in the hands of the Persians. Existing treaties with Poland and Austria, as well as policy and religion, urged the tsar against the Turks, and Constantinople has always been the point of attraction for orthodox Russia. Peter decided to attack by the Don and besiege Azov, the key to the sea of that name and whence the Turks made their plundering expeditions. An army of 100,000 men, many of them French (according to Voltaire), and other foreigners, formed the heart of the expedition. The attempt failed owing to the lack of a fleet to invest Azov from the sea and the siege was raised in 1695. Within less than a year Peter had constructed a fleet of 22 galleys, 100 rafts and 1,700 boats by 26,000 workmen assembled at the small ports of the Don. By July 1696 part of the outworks of Azov were captured and before the great assault was begun the place surrendered. This important event secured the Black Sea traffic to Russians and set a limit to Turkish power in that quarter. Ottoman power was practically broken by the Peace of Karlowitz on 26 Jan. 1699 between Austria, Poland, Russia, Venice and Turkey. Under that treaty Turkey ceded to Austria Transylvania, all Hungary north of the Marosch and west of the Theiss and all Slavonia except a small part between the Save and the Danube. A 25-years' peace was also stipulated. With Poland and the Venetian Republic terms of peace were agreed to without limitation of time. Venice retained her conquests in Dalmatia and the Morea; Poland recovered Podolia and Kaminietz. The truce with Russia gave her Azov and was at first for only two years, but was afterward extended into a peace for 30 years. Mustapha was deposed in a revolution in 1703 and died a year later.

Achmet III came to the throne in 1703 after having spent his 30 years of life in his prison home. But he had spent part of his time in the profitable study of politics and government, so that, unlike most sultans, he was not altogether unfitted for his task. As soon as he felt himself securely installed he dismissed the Grand Vizier and Mufti and ordered all the ringleaders of the late revolution to be put to death. He next appointed another member of the eminent Kiöprili family to be Grand Vizier, but the efforts of the latter failed before the internal confusion and discord. The public and officials turned against him and he was dismissed 14 months later and replaced by Baltadji Mehemet Pasha, a man risen from the people. Externally the country was at peace. After the defeat of Charles XII at Pultova by Peter the Great on 8 July 1709, the Swedish king made his escape from the field by swimming the Borysthenes. He fled to Bender, in Bessarabia, then Turkish territory, where he collected the remnants of his army — some 18,000 men — and endeavored for two years to entice the sultan into war with Russia. Achmet III was anxious to recover Azov and, therefore, ordered his Grand Vizier to put army and fleet on a war basis by raising a force of 200,000 men (August 1710). War broke out in 1711. Peter the Great set out for Poland in March, accompanied by his wife, Catherine. In the ensuing struggle the Russian army got into difficulties on the Pruth from lack of provision and the defection of Moldavia and Wallachia. The Turks and Tatars, though suffering heavy losses in a two days' battle, forced the Russians almost to the point of surrender when the Empress Catherine, who attended a despondent council of war in camp, suggested bribing the Grand Vizier, a notoriously avaricious man. Catherine gave her jewels and 200,000 rubles were collected and sent to the Turkish camp. Peter at the time lay sick in his tent, reluctantly consenting to make peace proposals. The Grand Vizier Baltadji agreed to make peace on remarkably mild terms, though the Russian envoys had been instructed to accede to any terms and sacrifices. By the Treaty of the Pruth (21 July 1711) Azov was restored to Turkey and the Russian fortresses built on Turkish territory at Taganrog, Saton, Kamennov and elsewhere were to be demolished, while the Azov Sea fleet was to be burnt. Further, Charles XII (who had not accompanied the Turkish army) was to be allowed to return to Sweden and left in peace by Russia. Peter the Great never recovered from this humiliation and it might be said that from this time Russia and Turkey were nearly always at war. In 1714 Turkey was again at war with the Venetian Republic. Austria intervened and declared war on Turkey and later dictated the Treaty of Passarowitz (21 June 1718), by which Austria obtained Belgrade and other cities, extending her influence over large portions of Wallachia and Serbia. The Turks lost Hungary. The interests of Venice suffered; the Morea was again confirmed to Turkey. In 1723 Peter the Great joined Turkey in an attempt to dismember Persia, a co-operation that was short-lived Mustapha III, who reigned from 1757 to 1774, became alarmed at the growing strength of Russia and demanded that Catherine II should remove her army from Poland. But during

TURKEY

her reign the Russians ravaged the Crimea and put an end to Turkish rule in the peninsula, while the Wallachian army conquered Bessarabia, including Bender, and penetrated into Bulgaria. While Turkey was preoccupied with the revolt in Egypt, which broke out in 1768, Catherine prepared further disaster for the Ottoman Empire. A Russian fleet defeated the Turkish navy at Chios and annihilated it in the port of Chesmé with British aid. The Russian commander, Alexis Orloff, delayed his projected attack on Constantinople and found the Dardanelles had been too strongly fortified in the meantime. But the Russians had recovered Azov, the Crimea, the shore of the Black Sea between the Dnieper and Dniester and made important gains in the Balkans. By the Peace of Kutchuk-Kainardji in 1774 Turkey was compelled to yield the Russian conquests, acknowledge Russian protection over the Christian subjects of the sultan and to open the Bosporus and Dardanelles to Russian merchant ships. In 1787 Turkey again declared war against Russia, but suffered defeat except at the battle of Belgrade, where the force under Selim III was victorious. The Peace of Sistova (1791) ended the wars between Austria and Turkey. Russia began another war against Turkey in 1807 and succeeded in nearly every encounter. The insurrection in Greece at the time when the Turkish army was engaged elsewhere was a severe blow to Mustapha IV. The Peace of Bucharest in 1812 closed a six years' struggle in favor of Russia. The Serbians rose against the Turks in 1815; Greece revolted in 1821 and declared her independence of Turkey in 1822. At the naval battle of Navarino (20 Oct. 1827) the allied fleets of France, Great Britain and Russia annihilated the Turkish and Egyptian fleets, thereby assuring Greek independence. A short war raged between Russia and Turkey in 1828–29, the latter being the loser. The Turkish war with Ibrahim Pasha is related under Egypt (q.v.).

Crimean War Period.— Up to the middle of the 19th century the Ottoman Empire had exerted a tremendous influence upon the history of Europe for over 400 years. The Turks had proved themselves not only redoubtable warriors, but a distinct peril to Western civilization and Christianity. The Turk conquered for the sake of conquest; he devastated and massacred, but made no effort to colonize or introduce tolerable government. In all the territories that fell under his sway the Turk was ever in the minority; he was not assimilated with the natives nor they with him; he was ever a stranger to the soil and his "government" merely an army of occupation to suppress the natives. The Mohammedan Turk looked down on those of other creeds with contempt: they could not be placed on a level with him. The conversion to a foreign creed was practically an impossibility except under compulsion. Islam found its converts only among those who had no religion of their own. Despite their frequent wars among themselves, all the other nations of Europe have certain interests and ideals in common — in commerce, literature, polity, religion, science, etc. The Turk shares in none of these excepting, perhaps, the material one of commerce. From the early incursions of the Ottomans into Europe, as has been shown, there were frequent coalitions among European states to resist the invader. It was reserved for the 19th century to witness the anomalous spectacle of Christian nations rushing to the defense of the Turk and the preservation of his dominions — at least in Europe. This political phenomenon is known as the "Eastern Question," which is treated under that head. The first important manifestation of this policy was the war in the Crimea (q.v.). Already in 1853 the Tsar Nicholas I described Turkey as the "Sick Man of Europe" to the British Ambassador and proposed a division of his property when the patient should die. The old Russian ambition for Constantinople has been mentioned. The other Turkish possessions in Europe at that time contained populations of more or less well-marked races which could be set up as independent states — as they eventually were. The Crimean War, in which France and Great Britain fought on the side of Turkey against Russia, resulted practically in a draw, though Russia was obliged to make important concessions to her rival by the Treaty of Paris.

In 1875 Bosnia and Herzegovina broke into open revolt, stung to desperation by intolerable abuses, and in February the six European powers launched the Andrassy Note, the first of a long succession of similar documents, most of which have been delivered in the same fashion, only to meet the same fate. The note demanded administrative reforms on a liberal scale, but nothing came of it. Though nominally acting in concord, the Powers at this epoch were far from being in harmony. The note having failed in its object, Prince Gortschakov, Prince Bismarck and Count Andrassy met in Berlin and framed the "Berlin Memorandum" (q.v.), in which the signatories declared it futile to accept the sultan's bare word and promise for reforms, and demanded material guarantees. The effect of the memorandum was nullified by Lord Derby's objection to the principle of interfering with the integrity of the empire, but it was published and noted by the Turks, though never formally handed to them. The Bulgarians broke out in insurrection in April, but were easily crushed with relentless ferocity. The internal condition of Turkey went from bad to worse and the financial situation became desperate; the interest on the public debt amounted to nearly $70,000,000, out of a total revenue of $100,000,000. Payment was stopped, Turkish stocks fell 50 per cent and the populace grew more and more furious against their rulers. Frequent demonstrations were made by the turbulent Softas (students), and at length the Grand Vizier and the Sheikh-ul-Islam were ejected from office, while Midhat Pasha, the leader already of a Turkish reform party, was given a place in the ministry. Within two weeks of this change the palace was silently surrounded with troops, the Sultan Abdul Aziz was made prisoner and dethroned by his ministers on a *fetvah* from the Sheikh-ul-Islam. Murad V was placed on the throne, and Abdul Aziz was found dead in the Cheraghan Palace 4 June 1876. According to the verdict of a number of European doctors he had committed suicide by cutting the veins in his arms with a pair of sharp-pointed scissors. The advent of Murad

was hailed with popular enthusiasm, as he was supposed to be liberal-minded and inclined toward political liberty. A short time, however, revealed that he was a weak-willed creature, quite unable to check the high-handed proceedings of his Cabinet, and on 31 Aug. 1876 he was unceremoniously deposed, not secretly, as his uncle had been, but deliberately and openly, and Abdul Hamid II, his younger brother, became sultan. For 28 years Murad lived a state prisoner; his death was announced 31 Aug. 1904.

Abdul Hamid at first gave no sign of his latent strength and energy. Not long before his accession Serbia had suddenly declared war on Turkey and proclaimed Milan Obrenovich «King of Bosnia and Serbia.» The storm of Turkish butchery and outrage turned loose in Bulgaria (see BATAK) roused the indignation of the civilized world and led to European diplomatic intervention. The British government presented a comprehensive «reform scheme» and proposed a conference to devise means for enforcing its execution. Although Midhat Pasha, now the Grand Vizier, was himself an advocate of reform, he believed that Turkey was capable of looking after itself without interference. Within two months of his accession the sultan played his first *coup*, designed to cut the ground away from under the feet of Europe by first promulgating a reform scheme of his own, even more comprehensive than the British one, providing for a constitution, a parliament, a premier, open courts, freedom of the press and all the administrative furniture of a modern state. Midhat was dismissed and banished on 5 Feb. 1877. Elections were held, several Christian deputies chosen and the Parliament was opened with a fanfare of trumpets and salvos of artillery on 19 March 1877. The speech from the throne, read by the sultan's first secretary, entered at great length into the condition of the empire and declared that the Constitution was intended to secure liberty, equality and justice to all. Almost for the first time the East was adopting one of the most distinctive institutions of the West. But the innovation, unfortunately, was launched at a critical time: civil war raged in the Balkans; Serbia, under armistice, was unfriendly; Greece was watching her chance to seize Thessaly; Crete and Montenegro threatened and, above all, war with Russia seemed imminent. The Powers, however, were determined on a conference, which was held in Constantinople and soon ended in smoke. The Tsar Alexander declared war on Turkey 24 April 1877 and lost no time in moving his troops across the Pruth. While the war was in progress the sultan prorogued his Parliament on 14 Feb. 1878 and it remained closed for 30 years. In the course of the war the Russians advanced almost to Constantinople, and it seemed that the age-long aspiration of expelling the Turk from Europe would be soon realized. Incidentally, Russia would also become mistress of the city of the Bosporus in accordance with the famous «testament» of Peter the Great. But the other powers of the Concert flamed out in jealousy of Russia and the British government actively intervened to save Turkey. Even the Treaty of San Stefano (q.v.), which Russia exacted from Turkey, was not allowed to stand, the Berlin Congress cutting down the Turkish sacrifices of territory. However, Rumania, Serbia and Montenegro were released from Turkish suzerainty and Bulgaria was left in only nominal dependence. Bosnia and Herzegovina were placed under the administration of Austria and a small part of Armenia was ceded to Russia. The treaty further obligated the sultan to introduce reforms into the remaining Christian provinces--an obligation that still lacked fulfilment at the close of the European War 40 years later. The result of the war was by no means very disastrous to Turkey; the loss of the Balkan principalities had long been inevitable, but she was still permitted to retain suzerainty over eastern Rumelia, which in 1885 broke away and united with Bulgaria. Turkey also lost Kars and Batum to Russia. The most serious blow was the war indemnity, but Russia proved indulgent and consented to easy instalments, thus providing herself with a Damocles' sword over Turkey. Just before the signature of the treaty, Great Britain concluded the Cyprus Convention, taking over the administration of that island and in return undertaking to defend Turkey in case of Russian aggression in Asia Minor. In 1881 Midhat Pasha was tried for alleged complicity in the murder of Abdul Aziz. He was «found guilty,» exiled to Arabia and finally strangled.

In 1882 the Arabi Pasha revolt broke out in Egypt, and the sultan at the outset encouraged it, as being directed against the growing dictation of Europe personified principally by the Dual Control. The viceroy Ismail had been deposed and held a prisoner in Constantinople, and his son Tewfik was running with hare and hounds, being also in partial sympathy at first with Arabi and his army, whom he knew to be working with the tacit approval of his suzerain. Later on, when the British expedition arrived, Tewfik threw over the rebels, though it was he who gave the order to return the fire of the British fleet. The sultan was invited to send his own troops to Egypt, but for some reason never made clear he declined the British invitation. The result has been the definite loss of Egypt, although the suzerainty had already become purely nominal under Ismail. By 1885 the Ottoman Empire had been shorn of Serbia, Rumania, Bulgaria, Montenegro, eastern Rumelia, Egypt, Cyprus, Tunis and Thessaly. A comparative calm reigned after the settlement of the Bulgarian question and Abdul Hamid devoted himself principally to improving his army and extinguishing all internal opposition to his arbitrary rule. It was not until the Armenian question loomed upon the horizon that European diplomacy again roused itself to activity on the shores of the Bosporus, though there was now a different grouping of influences. Since the war, Russia had been viewed with justified mistrust, and the sultan had leaned upon the Triple Alliance, headed by the German emperor, who had almost openly posed as his friend and protector in Europe, as Great Britain had bound herself to be in Asia. When Abdul Hamid saw signs of disruption between members of the Triplice, and England drifting into trouble both with Russia and France, who were joining hands, he decided to reverse his policy

and turn to Russia as a friend. No exact date can be fixed for this change, but it may roughly be said to have been inaugurated about 1889–90. It was at this time that the beginnings of disorders in Armenia were reported. Early in 1890 the churches of Erzerum were broken into and profaned, while a score of Armenians were killed and wounded. The Armenians then decided that their only hope of salvation was, at any cost, to bring about European intervention. The Trochak, a Russian branch, instituted a system of anarchism, bombs and dynamite, by which they counted on provoking the sultan to such massacres as should force the intervention of Europe. So far as the massacres went, their calculation was correct; but Russia, who was distinctly opposed to any establishment of an autonomous or independent Armenia, invariably hampered any proposal for active coercion of the sultan. That monarch, being confident of the non-participation of Russia, if not of her positive help in case of any act of force by other European powers, and also being steadily encouraged by Germany, took little heed of the threats and warnings issued by a Concert no three of whose members had the same views and almost all of whom were certain to protect him from aggression on the part of any one power that might attempt such a thing. The Sassun massacres of January 1895 brought more protests from European governments, to which the sultan replied that he was then engaged upon a project of reforms which he hoped to communicate within a month. Nothing happened up to September, however, when the Armenians organized a demonstration at the Porte, which was followed at once by a wholesale butchery all over Stambul, Galata and Pera. This was only a beginning, and for the next few months there was scarcely a district in Asia Minor which did not run red with the blood of Armenians. In spite of the most energetic paper remonstrances of the Powers singly, collectively and in groups, not a single individual was punished. At first, after the Convention of Cyprus, the task of guarding the rights of the Christian population was supposed to devolve chiefly upon Great Britain, who appointed military consuls and up to a certain point succeeded in remedying a few abuses. But toward 1890 — as soon as Russia had come to some terms with Turkey — Great Britain lost all influence. She appealed to all the signatories to the Berlin Treaty when the Sassun massacres took place, but only France and Russia responded, and they, apparently, only to prevent England from acting alone. The reform scheme eventually submitted by the six ambassadors, quite apart from its inherent defects, was foredoomed to failure from the certain knowledge of the sultan that Russia did not really recognize the existence of any Armenia; also that Germany had no particular interest in Asia Minor, as she carelessly stated, and that England did not consider the scheme as sufficiently guaranteed, but wanted something more which the other Powers would not back her in asking or obtaining. In fact, directly England wished to insist upon an immediate and categorical answer from the sultan, Prince Lobanoff wired from Saint Petersburg to the Russian Ambassador that "in no case would Russia co-operate in coercive measures, nor, indeed, would she consent to the establishment of a privileged Armenian province or provinces" (which England was pressing for) "to serve as a nucleus for a possible future Armenian kingdom." After months of fruitless discussion the sultan again emerged triumphantly from the contest by substituting another scheme of his own — which never materialized.

Having thus entirely defeated the fictitiously united Powers, the sultan turned his attention to the Young Turkey party, a group or relic of the Midhat faction which aimed at the regeneration of the empire by utilizing the best Moslem elements without interference or control from Europe. Its first article was ministerial responsibility, as opposed to palace autocracy, with ultimate ideas of representative chambers for legislation which should put an end to the worst abuses and raise the country from the slough of corruption into which it had fallen. In short, the Young Turks' object was to curb the arbitrary exercise of power by the sultan and give to every Turk and Christian some sort of legal status, though it was scarcely likely, having got rid of Midhat Pasha and all his associates by means of trumped-up charges and judicial murders, that Abdul Hamid would permit the seed sown by them to ripen and bear fruit. The chief sources of danger were the Softas and the students in the naval and military academies. Accordingly, these were mercilessly pursued with torture, drowning, beating and exile. As he had cowed the Armenians, so the sultan resolved to break the spirits of the Young Turks. Unlike the Armenians, they had not the passive sympathy of foreigners behind them, and they lacked the necessary finances. Not that cash was wanting among the people, but any man who ventured to subscribe was sure to be denounced and spirited away.

At the beginning of 1897 the sultan was probably stronger than ever before, despite the furious assaults made upon him by ostensibly united Europe. The Cretans once more broke out into revolt. Not only did the Powers refuse to let the sultan send more troops to the islands, but demanded that a large portion of those already there should be withdrawn. The Greeks then landed an expeditionary force under Colonel Vassos and proclaimed the island annexed to Greece, but the Powers protested and blockaded Vassos with a mixed fleet. The sultan speedily mobilized a large army on the Thessalian, Bulgarian and Serbian frontiers. Despite all warnings from the Powers, the Greeks raided Turkish territory and the sultan declared war upon Greece, with the consent, be it noted, of the Powers themselves. In a few weeks Greece was beaten to her knees, and now the Concert headed by Russia intervened, deprived the Turks of the spoils of victory, ordered them to evacuate conquered Greek territory and created the island an autonomous state under the high commissionership of Prince George of Greece, an arrangement which lasted till 1906. By the Balkan wars of 1912–13 Crete was finally annexed to Greece.

The outstanding events of Turkish history during the first 15 years of the 20th century were the perennial Macedonian feuds, an irregular civil war between Serbians and

Albanians on one hand and Greeks and Bulgars on the other, both being freely assisted by guerrilla bands from beyond the frontier. Bulgarian villages were attacked and their inhabitants assaulted or murdered by Greeks, while sanguinary conflicts occurred between Turkish troops and Bulgarian bands. The international gendarmerie established by the Powers was unable to cope with the insurgents, and its operations were impeded by the inefficiency and corruption of the judiciary. A revolt in Yemen and the lack of funds prevented the sultan from dealing with the difficulties besetting him on all sides. In 1907 the Porte, still suzerain over Bulgaria, made remonstrance to the latter as to the persecution of the Greeks. All the Balkan states seemed on the verge of war; European intervention was powerless; massacre and outrage continued. The Turkish revolution, engineered by the Young Turks, broke out in 1908. Almost bloodless in execution, it led to the revival of the dormant Constitution and the prorogued Parliament of 1878. Abdul Hamid accepted the inevitable and transformed himself into an ardent reformer and a pattern sovereign according to the best Western models. He suddenly became almost the most popular person in the empire. On 5 Oct. 1908 Prince Ferdinand proclaimed himself tsar of Bulgaria and declared his absolute independence of Turkey; Austria annexed Bosnia and Herzegovina. Abdul Hamid was dethroned in 1907 and banished to Salonica; he died on 10 Feb. 1918. His brother, Mohammed V, succeeded to the throne and soon became a helpless puppet in the hands of the Young Turk leaders, Enver Bey and Talaat Pasha. Italy declared war on Turkey in 1911 and took Tripoli. Before that war was ended the Balkan League declared war on Turkey in 1912, which was followed by another war among the members of the league in 1913, the results of which were destined to have important consequences in the great European War which broke out in the following year. All the events here touched upon will be found fully described under the different headings given in the list of cross-references below. Separate articles are also devoted to all the prominent characters concerned. JOHN B. MCDONNELL,
Editorial Staff of The Americana.

TURKEY, or THE OTTOMAN EMPIRE, Diplomatic Relations of the United States with. The opening of American diplomatic relations with Turkey, although delayed for nearly a half century after the achievement of American independence, was contemplated soon after the conclusion of the early treaties with the Barbary states. In 1798, following the formation of a European coalition (of Russia, Austria, England, Turkey and Naples) against France, the Russian Minister at London suggested to Rufus King (the American Minister at London) that the Russian government would be inclined not only to form a commercial treaty but also to use its influence in aiding the negotiation of such a treaty with Turkey. Mr. King while recognizing the advantage of such a treaty with Russia also discreetly admitted that extension and establishment of the American trade in the Levant would undoubtedly be an object of importance. On 11 Feb. 1799, William Smith, Minister Plenipotentiary to Portugal, was commissioned Envoy Extraordinary and Minister Plenipotentiary to Turkey, but did not go.

The first American vessel which raised the American flag in the Bosphorus was the American frigate *George Washington*, which was seized in 1800 by the Dey of Algiers and forced to carry an Algerian ambassador to Constantinople. For 30 years thereafter, American commerce in the eastern Mediterranean was conducted under the protection of the English Levant Company.

In January 1815, the Russian government in a note to Levett Harris, chargé at Saint Petersburg, offered to obtain through its Minister at Constantinople the good offices of the sultan in securing for the American government favorable arrangements with Algiers.

The first attempt to arrange commercial relations with Turkey on a treaty basis was made in 1817, and thereafter followed by various other unsuccessful attempts.

Finally in September 1829 President Jackson appointed for that purpose a commission composed of Commodore Biddle, David Offley (the American consul at Smyrna) and Charles Rhind of Pennsylvania. Rhind, who preceded the others to Constantinople, negotiated a treaty conceding trading privileges of the most favored nations and containing a separate secret article which allowed Turkey to purchase timber and to build ships in the United States. This Treaty of 1830, signed by the three commissioners, was ratified by the Senate only after rejection of the separate article. It was proclaimed 4 Feb. 1832. In exchange of ratification, which occurred at Constantinople, the American government was represented by David Porter of Maryland, who was commissioned chargé d'affaires on 15 April 1831 and later as Minister Resident on 3 March 1839. The first Turkish diplomatic representative in the United States was Blacque Bey who presented his credentials as Envoy Extraordinary and Minister Plenipotentiary on 23 Aug. 1867.

In 1868 a question arose in regard to the contents or stipulations of the original draft of the Treaty of 1830 which was found to differ from the translation ratified by the American Senate. The American government complained that the arrest and imprisonment of two Americans was contrary to Article 4 of the Senate version which provided for trial by the American Minister or consul in such cases; but the Turkish Foreign Minister replied that the treaty clause quoted was not in the original Turkish document and, therefore, was not correct.

Meantime, in February 1862, the two governments negotiated a new commercial treaty which changed minor provisions of the Treaty of 1830 but contained no provision in regard to extraterritorial jurisdiction. This treaty although valid for 28 years was terminable by a notice of one year before the expiration of either 14 or 21 years. In 1874 and again in March 1883 the government of Turkey gave advance notice, unaccepted by the United States, but neglected to submit the required notice at the proper time. It insisted that the notice of March 1883 was given properly and, therefore, that the treaty was abrogated after 5 June 1884. Soon thereafter, however, it invited the negotiation of a new treaty.

A third treaty with Turkey, an extradition treaty, was negotiated in 1874 and proclaimed 26 May 1875.

By the Treaty of 1830 the United States obtained recognition of the rights of its citizens to pass the Bosphorus and the Dardanelles and to enter the Black Sea which the Sultan until near the close of the 18th century had

guarded from foreign vessels as jealously as he protected his own harem from outsiders. This right for merchant vessels had been granted to Russia in 1774, to Austria in 1784, to Great Britain in 1799, to France in 1802 and to Prussia in 1806 and was finally granted to all nations by the Treaty of Paris in 1856 as modified by the Treaty of London in 1871. The American government, having never adhered to the treaties of Paris and London, claimed the right to send into the Black Sea ships of war which were prohibited to other foreign powers by the treaties, but while reserving all question of right it entered the Dardanelles in such case only after asking permission of the Porte.

Under the Treaty of 1830, which was the basis of all American rights in Turkey, the American government continued to claim the privileges of extraterritoriality. This contention, based upon an admitted mistranslation of the treaty, was opposed by the sultan's government; but American consuls have continued to exercise extraterritorial privileges in Turkey and in Turkish dependencies and in 1900, after the privilege for which America contended had been granted to other nations, the American insistence of right was placed on the most favored nation clause. In 1914 Turkey abrogated the privilege in the case of all nations. This action was promptly protested by the principal nations and the final outcome awaits the results of the peace negotiations terminating the war.

The question of naturalization long remained a prominent source of friction. The Turkish government refused to permit the return of its subjects who were naturalized in the United States after 1869, and frequently expelled them when discovered on Turkish territory. A naturalization treaty negotiated in 1874 to settle the controversy was approved by the Senate after amendment, but, because of various declarations attending the exchange of ratifications, was never proclaimed or put into effect. Later efforts to induce the government of Turkey to accept the treaty in the spirit contemplated by the Senate amendment were unsuccessful. Finally, in 1889, the Turkish government seemed willing to accept it, but following the reapproval of the Senate with a proviso against retroactive effects, it resorted to tergiversations and thereby prevented ratification.

The importance of an understanding to relieve disagreeable situations resulting from Turkish policy was emphasized in recent years by the increased immigration of Armenians and Syrians to the United States and was reflected in the recognition of larger importance of American diplomatic representation at Constantinople illustrated in the service of Oscar Straus whose triple embassy covered the years 1887–89, 1898-1901 and 1909–10.

Although Americans always openly sympathized with Christian nationalities subject to Turkey, the American government until recently hesitated to participate with the European concert of powers which so often intervened or remonstrated against conditions within the Turkish Empire. In 1894, following American Senate resolutions against reported "atrocities" by Turkish officials, President Cleveland, who had declined the invitation of Turkey to investigate conditions, decided that American action would prove inconvenient because of the European concert under the Treaty of Berlin. Later, the possibility of American intervention was indicated in the increased American indignation resulting from the Armenian massacres, and probably was prevented only by the influence of ancient traditions in causing the American government to avoid any action by which it might become involved in the mazes of the Eastern Question. More recently, American diplomacy became more active at Constantinople. This activity encouraged the proposal, at the close of the World War, that the American government assume a new responsibility by accepting the mandatory of Armenia, or in the execution of an international guarantee of the free passage of the Dardanelles.

The larger number of American diplomatic disputes with Turkey originated in questions concerning the educational and charitable institutions established in the Turkish Empire by American missionaries who insisted upon privileges under provisions of a series of old capitulations of sultans granting substantial self-government to foreign communities in Turkey. Although these capitulation rights were conceded by the government at Constantinople, their enforcement resulted in difficulties. In 1903 the government of Turkey recognized the justice of American demand for official legalization of American educational institutions in Turkey, based upon a similar privilege granted to France in 1901, but it failed to issue the necessary decrees until 1907, when the privileges were finally granted in return for certain commercial concessions. It failed, however, to acknowledge by treaty the American claims to indemnity for injury to missions or other American property in periods of internal disorder.

In 1906, after considerable opposition, the Sublime Porte finally conceded the demand of the American government to be permitted to raise the rank of its diplomatic representative from minister to ambassador, who thereby obtained the right of personal interview with the sultan to discuss official matters. This arrangement, first unsuccessfully proposed to Turkey by President McKinley, was especially necessary to remedy unsatisfactory relations as conducted through the irresponsible Turkish Secretary of Foreign Affairs.

Another subject of discussion resulted from increase of American commercial interests. In 1907 the American government successfully demanded an equal right with European powers to approve or disapprove proposed increases in Turkish tariffs. Recently American capital has been attracted by new opportunities for development in Turkish territory.

In conflicts between Turkey and the Balkan states and in the conflict between Turkey and Italy in Tripoli culminating in 1913 in the almost complete destruction of the Turkish Empire in Europe, the United States had "only a remote and detached interest," but in the later world conflict in which Turkey was an ally of Germany and Austria the American government recognized a duty which compelled it to participate actively in war against the Central Powers and in the subsequent peace nego-

tiations which determined questions relating to Turkey and her dependencies.

JAMES M. CALLAHAN,
Professor of History and Political Science, West Virginia University.

TURKEY, or THE OTTOMAN EMPIRE, AND THE WORLD WAR. The Turkish Empire was from the very start an anomaly. When at the zenith of its power and expansion it embraced, like the Roman Empire of old, large tracts of land in the three continents, Asia, Europe and Africa. But at no time was it consolidated. Always it was a mere congeries of territories differing greatly one from the other in civilization, race, speech and religious faith. It was built on rude conquest, and was solely maintained by terror and arms. The dominant race in it, the Ottoman Turks, was always the minority and always, too, intellectually below par in comparison with the subjected majority. After 1540 the process of slow decay and disintegration set in. Under a few able rulers Turkey rallied somewhat, and in 1683, when Mustafa Pasha went with an army of half a million to lay siege to Vienna, the abnormal Asiatic power for the last time in history — like an expiring candle, flickering or flashing — practically closed its meteoric career. Since then it has, more or less justly, earned her nickname of the "Sick Man." According to whether the medicine administered by his keepers agreed or disagreed with him, Turkey's plight has for over 200 years past called urgently now for a cure or anon for a sleeping potion. Throughout the whole of Turkish history the relations of Turkey with the two western European powers, England and France, have been quite or almost friendly. Turkey was even a number of times the ally of one or both of them. Louis XIV of France throughout his long and troubled reign was in alliance with Turkey against the Hapsburgs. During the Napoleonic era England was Turkey's silent or outright supporter. In fact, England's political and economic interests were seldom running counter to those of Turkey. Her aim was all the while to maintain a feeble Turkey, but an intact one, especially since British India loomed up as important and as easy access to those rich possessions had to be kept open. France, it is true, had special interests in Syria, but these needed not necessarily to conflict with Turkish or French policies. During the Crimean War both France and England stood on the side of Turkey against Russia. Quite late, only since the period of Peter the Great, Russia collided with Turkey, but since then a score of wars were fought in which Turks and Russians faced each other with hostile intent. And for the space of 50 years one of the favorite Russian ambitions has been the destruction of Turkey and the acquisition of Constantinople. As for the Central Powers, Austria-Hungary and Germany, the former waged more frequently war with Turkey, ever since the fall of Christian Constantinople in 1453, than any other country. Twice Vienna was besieged by the Moslem Turks and their hosts, in 1529 and 1683. For 150 years nearly the whole of Hungary was under Turkish dominion. Transylvania was Turkish for even a longer space of time. During the 16th, 17th and 18th centuries Austria was almost incessantly at feud with Turkey. For a long time Austria constituted itself the champion of the Christian populations on the Turkish Balkan, until deprived of that rôle by Russia. With Germany political relations of more than temporary importance were of much more recent date. With Prussia, as the more bellicose portion of Germany, Turkey entered only into relations since the reign of Frederick the Great, the second half of the 18th century, and these relations were consistently amicable ones. But Turkey held rather aloof from Prussia and from the latter's creation, the new German Empire, even as late as the accession of its last ruler, William II, in 1888. Since then, however, there was a decided change. The Kaiser took infinite pains to strengthen the political and economic ties with Turkey. The Turkish army was reorganized by Prussian officers and put on a Prussian footing, the most effective work in turning the hitherto but loosely coherent and badly disciplined Turkish hosts into a formidable fighting machine being performed, at the behest of William II, by Gen. Baron von der Goltz, although from Moltke on a number of other efficient Prussian drill masters had devoted many years to the preliminary task. Other material bonds, as well as intellectual ones, followed in rapid succession. William II let no opportunity escape to assure Turkey of potential German support. During his trip to Palestine he grandiosely proclaimed himself the admirer and, in a manner, the powerful protector of not alone Turkey, but of the entire Moslem world. The national policy of Germany, as managed from Berlin, embraced a quasi-protectorate over decadent Turkey, with its threatening tentacles turned more especially toward Britain and British India. As relations with Germany became more and more intimate during the long reign of Abdul Hamid, financial and economic schemes began to multiply, all directed from the Foreign Office in the German capital. These latter culminated in the planning and partial construction of the Berlin–Bagdad Railroad, a line which was chiefly meant to serve Turkish strategical schemes in a future war wherein Russia, England and France should be involved, but which also was to connect by the briefest route Berlin with the Turkish part of the Orient, and to bring more especially Mesopotamia within the sphere of German influence and thus not only checkmate the British but to threaten permanently the approaches to British India. Anatolia to the northward, that is, the heart and source of purely Turkish power, was to be brought near the south on the Euphrates line. The complete economic conquest of Turkey, at the instance and with the earnest collaboration of the imperial staff at Berlin, was elaborately planned and had already in good part been accomplished when the World War broke out in 1914. The overwhelming bulk of the Turkish masses did not fall in with these projects, not even while during 1915

and 1918 the fate of Turkey trembled in the balance. But Enver Bey, the all-powerful War Minister, and Talaat Bey, the equally omnipotent Secretary of the Interior in Turkey, who completely terrorized the feeble and sickly sultan, Mohammed Rashid, were apt pupils of German statecraft, and until the complete collapse of Turkey came these two and their following had it all their own way.

The causes that induced Turkey late in 1914 to enter the World War on the side of Germany now lie clear before the eyes of the world. They are intimately connected with and lie enwrapped in the coming of the so-called Young Turk party to power. When in 1908 the absolutism of Abdul Hamid came to an end and the wholly unexpected and bloodless revolution that deposed him and in a sense modernized Turkey and its government so successfully brought the Young Turks with their Parisian ideas of liberty and progress on the stage, the entire West almost expected nothing less than a complete rejuvenation and liberalization of Turkey, and for a short time there were apparent signs of that. During this short transition period German national statecraft, which had strongly supported the personal régime of the autocratic Abdul Hamid, was under an eclipse. But the Young Turks very soon upset their own initial program, and from setting out as spokesmen of Western liberalism they turned into more ruthless advocates of force in the service of their ideals than had been Abdul Hamid himself. Instead of fostering a rational program of internal reform they became Nationalists, Panislamists, finally Panturanians. That is to say, their aims became the following: enforcement of a policy recognizing only the Ottomans as instruments and worthy servants of the state, and the rooting out by every means, of alien, that is, non-Turkish and non-Moslem elements within the Turkish Empire, such as Armenians, Syrians, Nestorians, Arabs; the spreading by persuasion or force of the doctrine that Turkey is the cradle and instrument of Islamic rule, within and abroad; the gathering into one fold, into one great state of the future, of the whole Turanian race. As early as October 1911, the Young Turk Congress adopted resolutions in favor of Panislamism throughout Turkey and of suppression of every other type of religious practice and faith. "Sooner or later," the resolution ran, "the complete Ottomanization of all Turkish subjects must be effected." Djelal Noury Bey, one of the chief mouthpieces of Turkish full supremacy, in a late work advocated strongly the "Turkification" of Mesopotamia, of Hedjaz and of Yemen, Arabia, and the Arabs were bluntly told that there "were neither Arabs nor an Arab fatherland." Ahmed Shereef Bey, another Young Turk leader, wrote in a similar sense in the great organ of the party, the *Tanin*. This sort of propaganda, inflaming official Turkey against its own subjects, was spread for years after the Young Turks had achieved their easy victory in 1908, in all the provinces of Turkey, and it was this which made the deportations and wholesale massacres of the Christians in Turkey and of the Armenians in particular, of all the non-Moslem or non-Turkish subjects there so cruel and ruthless. Coupled with this was an all-embracing Turanianism. Ahmed Shereef Bey wrote: "If all the Turks in the world were welded into one large community a strong nation would be formed worthy to take an important place among the other nations of the earth." It was this underlying dogma which inspired the Turkish armies in Asia during the brief period of the World War when they were triumphant in the Caucausus and in West Persia to invade the latter and attempt to annex those districts where people of Turanian stock were predominant. The great Russian victory of Sarikamysh, 1917, squelched these dreams in blood. Tekin Alp, another equally influential Young Turkish leader, had this to say: "If the Russian despotism is, as we hope, to be destroyed by the brave German, Austrian and Turkish armies, 30,000,000 to 40,000,000 Turks will receive their independence. With the 10,000,000 Ottoman Turks this will form a nation of 50,000,000, advancing toward a great civilization which may perhaps be compared to that of Germany in that it will have the strength and energy to rise ever higher. In some ways it will be even superior to the degenerate French and English civilizations." To doctrines such as the above, namely, teaching salvation for the decrepit Ottoman people through the help of Panislamism and Panturanianism, had been changed the Liberalism, the "brotherhood of man" ideas that first inspired the Young Turkish movement that triumphed so easily in 1908.

When, therefore, at the beginning of the World War, in the fall of 1914, Turkey was urged by both sets of belligerents to join them, the soil was well prepared for her entry into the war on the side of Germany. For the dominant currents of opinion ran strictly counter both to British, Russian and French interests and aims. Britain was threatened in her Indian rule by the dogma of Panislamism — it might mean the revolt or weaning away of her 60,000,000 Mohammedan subjects if the Central Powers and Turkey should prove victorious; she had, besides, always advocated the equal rights of the non-Turkish populations in the Ottoman Empire. This applied with still greater force to Russia, and French aspirations in Syria would also be frustrated if Panislamism should prevail. On the other hand, no such considerations were apparent in the case of Germany and Austria. Again, the Turkish army was German-trained and partially so officered. This was one of the deciding factors that led to Turkey's siding with Germany in the tremendous struggle, that and the belief that militarily Germany was invincible. There were minor reasons as well tending in the same directions. For economic reasons England, France and Russia had never consented to Turkey's raising her rates of import or export duties. Yet these were, from the Turkish point of view, wholly inadequate and contributed very largely to Turkey's poor finances. The Turks also strongly desired the complete abolition of consular jurisdiction, within Turkish territory, abuses of which they seriously complained of. Much Turkish pride had been roused on the latter point. Turkey likewise found much fault with the state of economic, financial and political tutelage in which, as she averred, the three powers spoken of kept her. They wished,

therefore, to utilize the World War for casting off this "yoke," as it seemed to them. These considerations, all of them strong and likewise all of them coinciding so entirely with the things striven for by the ruling clique, coterie, or whatever one may term it — for just a handful of men, Enver, Talaat, Niazi and Shevket, held Turkey's destiny in the hollow of their palms during the years that Turkey fought Russia and the Western Powers,— vanquished any misgivings which Turkey, especially the more conservative portions of her population, may have had. These considerations, too, stifled the voice and benumbed the conscience of the Turkish government and official circles in regard to the Armenian and Syrian atrocities later on. Classic witnesses for this are two credible and highly respectable Germans who saw all and spoke out. One of them was Dr. Martin Niepage, of the German Technical School at Aleppo, who resigned his charge because the war crippled the school and who addressed a strong letter of protest to the Reichstag in respect of these cruel outrages against Ottoman Christians. Incidentally he passes judgment on the "civilizatory mission" of the Turks, saying: "Of all our pupils in the schools and colleges of Turkey the pure Turks are the most unwilling and the least talented. From my personal experience I can only prophesy that the Turks proper will never achieve anything in trade, industry or science." Another just as competent witness is Dr. Karl Wiedenfeld, professor of political sciences at Halle.

WOLF VON SCHIERBRAND,
Formerly Secretary to American Minister to Teheran, Persia.

TURKEY-BUZZARD, the best known and most widely distributed of the American vultures (*Cathartidæ*), its range including the greater part of the United States and the entire South American continent. It is about two and one-half feet long, its wings may extend six feet and it weighs about six pounds. The plumage is blackish brown, the naked head is red and the bill white; the scientific name is *Cathartes aura.* From about the latitude of Philadelphia northward the turkey-buzzard is migratory and visits New England only rarely, but throughout the remainder of its range it is chiefly resident. Like other vultures its principal food is carrion, but insects and small living mammals, reptiles and the young and eggs of birds are also eaten. Especially in the South, where it consorts with the black vulture, this species performs a most valuable service as a scavenger. To a considerable extent gregarious the common attraction is generally the presence of some carcass. Notwithstanding the generally repulsive habits of the turkey-buzzard its powers of flight must claim admiration; seemingly for hours at a time it soars in widening circles, often at a great height, and scans the earth in quest of a meal. The actions of any one bird when food is discovered attract others, and these again others, until many have gathered to the feast, often from great distances. In this manner all of the buzzards over a large area keep in touch with one another and any decomposing carcass is certain to be discovered and removed. Turkey-buzzards nest in pairs or in small communities, building their rude nests on the ground often by the side of a fallen log, or an old rotting tree stub or in a cave among rocks and always in out-of-the-way places in thick woods. The eggs are one or two in number, nearly three inches long and dirty white spotted with various browns and lavender. The nestling birds are thickly covered with white down. The rookeries are often very foul. See VULTURE.

TURKEY-CORN. See SQUIRREL-CORN.

TURKEY ORDERS AND DECORATIONS. See ORDERS, ROYAL.

TURKEY-RED, a color, originally produced on cotton cloth, rivaling the rich red obtained in dyeing wool and more permanent than any other red dye. It is obtained by the use of madder, in conjunction with an intricate and tedious method of dyeing, the three most essential processes of which are the impregnation of the cloth with an oleaginous soap, the mordanting with alumina and the dyeing with madder. The theory of these several processes is little understood and for that reason the long and repetitious method has never been successfully shortened. The art is supposed to have originated in India and from there was introduced into Turkey, where Adrianople was long the seat of the industry. From this fact comes the name Adrianople-red, by which the color is sometimes known. In the middle of the 18th century Great Britain and western Europe began the manufacture of turkey-red fabrics and in portions of France, in Glasgow and in Lancashire the industry has assumed importance. Besides being used in the solid color, turkey-red cloths are used in the manufacture of cloth "prints," the red being bleached from the design wherever it is desired to leave white or impose another color.

TURKEY-STONE, or **TURKEY OIL-STONE,** a very fine-grained silicious rock, highly prized as a honestone. It comes from Asia Minor.

TURKISH BATH, a popular form of hot steam or hot air bath in which the bather after being subjected for some little time to a considerable temperature is vigorously rubbed down, and is then conducted through a series of cooling chambers till he has regained his normal temperature. The secretions and accretions are completely removed from the skin, which is left free to perform its functions.

TURKISH LANGUAGE. It belongs to the linguistic group known as the Ural-Altaic

or Finno-Ugrian. Of the idioms forming part of this group the Turkish holds premier place because of the great size of territory in which it dominates and because of its conformity of type. In structural points it excels within its own domain. Properly speaking, all those dialects spoken as far east and north as the Lena River in Siberia, and all of which are nearly related, may be classed as Turkish. But general usage confines the term to the language of the Ottomans, or Turks proper, with its centre in Anatolia, Asia Minor. The two characteristic peculiarities of the Ural-Altaic family, viz., agglutination and vowel harmony, are found in great strength in the Turkish. The first of these, agglutination, makes possible the automatic formation of conjugations, the root of the verb in all these cases remaining unaltered at the head of the word. Thus, for instance, *sev-mek,* to love, becomes *sev-ish-mek,* to love each other; *sev-ish-dir-mek,* causing to love each other; *sev-ish-dir-il-mek,* causing to have loved each other; *sev-ish-dir-il-me-mek,* not causing to have loved each other, etc. As to the purity of vowel harmony, invariably no soft vowel may be employed in a word the stem of which does not contain it; thus, *pederiniz,* your father, but *dostunouz,* your friend. Suffixes are usually inserted, as *yazdim,* I wrote, *yazmadim,* I did not write. The grammatical forms are abundant, logical and efficient. To give an idea of the amplitude and flexibility of these grammatical forms, it may be mentioned that the mutations of which each Turkish verb is capable have been computed to run up to a score of thousands. Yet withal the rules are so simple and clear that the memorizing of 44 syllables or particles enables the student to construct himself and understand the whole series. Another unique feature is that the Turkish grammar has but one conjugation and no irregular verbs save the few auxiliaries. There is no gender for noun, pronoun or adjective, and the latter is not subject to any change except for comparison. The Turkish syntax is also peculiar, the unit of expression being the paragraph, and there being no punctuation. As a rule the subject of the dominating verb is put at the beginning, or near the beginning, of the paragraph, and all subordinate clauses have their verb in the participial form, and the meaning of the whole phrase being not apparent during the building-up process until the chief verb, somewhere near the end, makes the sense clear.

But while thus the grammatical structure of Turkish is purely and consistently Ural-Altaic, the stock of words in it, notably that used for literary purposes, has been greatly added to from Persian and Arabic, as well as European tongues, while the original number of Turkish words has correspondingly shrunk. Its alphabet Turkish has borrowed from the Arabic, with five new consonants added to the original 28 Arabic. The adoption of the Arabic alphabet, which was done for purely religious reasons, was a grave mistake from the linguistic point of view, as phonetically the Turkish and the Arabian differ very materially from each other, and some of the Turkish sounds cannot be properly reproduced in Arabic at all. One of the five additions is, besides, purely Persian, and another purely Turkish. Like the Arabs and Persians the Turks read from right to left. There is, however, a variety of script signs in use, such as those only employed for *fermans* (or official decrees), for poetry, for letter writing, etc. The most interesting forms of Turkish writing are those used on the inscriptions found in Siberia, near the Yenisei River; these contain historical records, a few of them dating back to the 4th and 5th centuries A.D. Those inscriptions met with north of Lake Baikal, in Mongolia, are also of great archæological importance, recounting as they do the deeds of Bilgä Kagan, and those of Kara Balgassun, dating from about 800 A.D., are also worthy of note. In all these ancient records the alphabets used are of Aramaic derivation, some simple and rune-like in shape, others, of more recent date, more complicated.

WOLF VON SCHIERBRAND,
Formerly Secretary to American Minister to Teheran, Persia.

TURKISH LITERATURE. As Islam was the gift of Arabia and Persia to the Turks, so also has their literature been powerfully influenced by these two countries. Nay, the sober truth is that nearly all their higher education dates from there, at least up to the period of the Crimean War, but a few generations ago. As a consequence, there is relatively little of originality in Turkish literature. However, it is customary to subdivide it into three periods: The earliest, when Turkish writers first arose in central Asia and India, and when they employed for the most part Persian as their medium of expression, about 900–1500 A.D.; the middle period, about 1500–1850 A.D., when Arabic was both their model and inspiration in literature, save only in poetry; and the modern period, since the middle of the 19th century, when they turned to the Western nations, preferably the French, for instruction and guidance. It goes without saying that, in a general way, during the two older periods Turkish literature closely resembles that of the chief Oriental writers of those times, both in aims and style and in subject matter, and that being largely imitative it is to a great extent devoid of those strong traits that are found in other, in purely national, literatures. In fact, much of the best literature written by Turks during those 900 years is necessarily swallowed

up by, and forming an integral part of, Persian and Arabic literature, as also it is mostly couched in those two tongues and colored by their idiosyncrasies. The last and shortest period, that of 1850 to the present day, is again too strongly tinctured with the Gallic spirit to be taken as a fair representation of the Turkish mind, although «realism» has been its chief motto,— the realism of Zola usually.

In point of time the earliest literary records of Turkish writing are the well-known inscriptions in central and northeastern Asia, but these have almost solely an archæological, and not a literary, value. Of considerable merit is a genealogical history of the Tatars by Abul Ghazee, from as early as the 12th century, notable mainly for its pristine Turkish. The author of 'Baz Nameh' a lengthy poem descriptive of the delights of falconry, is by one of the best of the 2,200 Turkish poets (among whom there are but seven women) and rhymesters enumerated in a history of Turkish literature by Baron Hammer-Purgstall. Unfortunately the poem is anonymous. Suleiman (d. 1403), author of 'Mewlid-i-Nebi,' a famous lay celebrating the birth of the Prophet and read in mosques these last 500 years with powerful effect, first wrote in a Turkish approximating that of to-day. Shekhi (about 1440), author of the 'Khar Nameh' (Book of Donkeys), introduced the Persian romantic epic with the Turks. Burhan-ed-Deen, a descendant of Genghis Khan, who lost his life in 1398, an adventurer and great warrior, left some poems in Turkish, although closely modeled after the Persian style. Amud-ed-Deen, writing under the pseudonym of Nesimi and a man strongly influenced by Sufeeism, wrote early in the 15th century. But being a freethinker and heretic, he was (in 1417) flayed alive in Aleppo. All his writings breathe, however, a joyous spirit. Ali Sheer, writing under the name of Nevayi (d. 1500), was doubtless a poet of considerable pretensions, who in order to have the necessary leisure for writing resigned early from the lucrative office of Grand Vizier to Sultan Husseïn. His writings show much humor and power of expression. Babr, a scion of Tamerlane, and conqueror of a part of India (in 1525) was also quite a writer, but confined himself to prose. His campaigns he has himself described in rather rude but highly expressive Turkish. Lami is probably the most productive of all Osmanian poets. His fame rests chiefly on his four great epics. He died in 1531. Baki, of obscure origin, is held to be the greatest lyric genius the Turkish race has produced. But while fluent and often flamboyant, his thoughts are nearly altogether borrowed from the Persians, especially from Hafiz. Baki's output was voluminous, but much of it has not survived. A little more mental independence may be ascribed to Fazli, likewise a lyrical poet, who lived and flourished during the reign of Soliman the Great and died in 1563. His fine allegorical poem, 'Gül u Bülbül' (Rose and Nightingale), has been translated into several languages, and is in part quite modern in its train of thought. Even greater originality is shown by Mesehi (d. 1512), whose love sonnets addressed to the boy beauties of his town, both in metre and in diction, are elegant productions. Rewami (d. 1523) cultivated as his specialty dithyrambic poems celebrating the festivals, banquets and great processions of his day. Sa'ad-ed-Deen, perhaps the best-known poet of his day, died in 1599, when Arabic influences began to permeate Turkish literature. His life was a very active one, his career beginning as a great chieftain and ending as Sheikh ül Islam, in the reign of Mohammed III. His great work was named 'Taj-et-Tevarikh,' a laudatory history of the Turkish Empire and its conquests, but its chief blemish is its superabundance of foreign vocables. The greatest poets of the 17th century were Nefi (d. 1635) and Nabi (d. 1712). The latter's *ghazels* are among the finest of this distinctly Oriental form of poetry. Nabi's real name was Yousouf, and he resided in Urfa, the recipient of a modest pension from the sultan. One of his longer poems, the 'Kairiyeh,' has been done into French. Kiami, whose real name was Abu Bekr, and who died in 1791, was a successful imitator of the earlier Turkish poets. In historical works Turkish literature is very rich. But the common defect of all Oriental historical writings, exaggeration and strong partisanship, clings to them, of course. Among them all may be mentioned Katib Tshelebi (Hadja Khalfah), who died in 1658, leaving behind him a great mass of valuable manuscript writings, mainly historical and geographical. Rashid (1660–1721), Naima Efendi (1591–1659), Sami, Shakir and Sübhi (all three about 1730), Izzi, Wassif (1750–70), Enveri, Dshefdet (1774–1825), Assim (1787–1808), Lutfi (from 1830 on), are some names of note. The works of these writers are very voluminous, but nearly all, except in details, utterly unreliable. Some monographs, however, are important, such as that by Kemal Pasha Sa'adi, who as a contemporary and actor described the events preceding and the campaign ending in the memorable battle of Mohacz (1526). Of geographical works, mainly fancifully descriptive, some have been translated by Hammer-Purgstall into English (London 1834). Another chapter of Turkish literature, as yet very inadequately gone into and promising rich treasure, is that comprising anonymous collections of popular tales, buffooneries, etc., such as the 'History of the Forty Viziers,' a cycle of stories rich in racy humor and wit, although rather frequently obscene; the 'Life of Nasr-ed-Deen Hodja,' a collection of similar scope, said to have emanated from some unknown Turk of Anatolia; 'Siret-i-Sejjid Battâl,' a sort of Don Quixote; the 'Shah Miran,' a collection of Turkish fairy tales, etc. Since the Crimean War a movement set in, partly political, partly literary in its nature and best known as the Young Turkish. There had been before that an enormous number of Turkish works translated from European languages, mostly French. After 1850 this tendency increased greatly. But hand in hand with it went a rebirth, or a new adaptation of Turkish to modern thought. Ibrahim Shinassi was its first leader, and Mohammed Emin its most eloquent interpreter, his poems being striking, ringing true and full of power and elemental passion. Among the band of «realists» and «purists» initiated by the latter deserve mention: Amed Vefik Pasha, author of a dictionary (d. 1893); Ahmed Midhat Efendi, novels, essays (d. 1905); Kemal Pasha (d. 1878); Jevdet Pasha, the his-

torian, Zia Pasha, the poet and essayist, Ebuzzia Tewfik, the critic and writer.

WOLF VON SCHIERBRAND,
Formerly Secretary to American Minister at Teheran, Persia.

TURKISH SPY, The. Giovanni Paolo Marana (1642–93) was a Genoese political refugee gifted with a keen mind, cosmopolitan political interests and a facile pen. Finding himself in financial straits, he began in Paris in 1684 the publication of 'L'espion du Grand Seigneur dans les cours des princes chrétiens,' a series of little volumes of letters addressed by "Mahmut the Arabian" to officials and friends in Turkey. This scheme, then novel, gave opportunity for relatively free comment on Continental politics in the days of Cardinal Mazarin and the young Louis XIV and of French society and manners in the hey-day of Versailles. The idea was keenly relished. Three other volumes had followed by 1688, afterward increased by other hands to nine in the edition of 1756. The substance of these four volumes forms the first volume (1687) of an English version afterward extended to eight with this descriptive title page: "The eight volumes of Letters writ by a Turkish Spy who lived 45 years undiscovered at Paris giving an impartial account to the divan at Constantinople of the most remarkable transactions of Europe and discovering several intrigues and secrets of the Christian courts, especially that of France, from the year 1637 to the year 1682, written originally in Arabic, translated into Italian and from thence into English and now published with a large historical preface and index to illustrate the whole." The translation was apparently by William Bradshaw, revised by Robert Midgley. It passed through at least 25 editions. The volumes from the second onward appeared first in English. Whether they were translated from a French manuscript, possibly Marana's, is uncertain. The opportunity for political satire contained in Marana's idea delighted Swift, who commends it in the 'Journal to Stella.' It was often imitated in England and notably in France in the 'Persian Letters' of Montesquieu. Consult 'Dictionary of National Biography' (Vol. XXXVII, 366, 367), Art. "Midgley."

B. W. WELLS.

TURKOMANS, tėr'kō-mąnz, a group of nomadic Tatar tribes occupying the regions to the east and south of the Caspian Sea. Other related tribes, known as the western Turkomans, are settled further to the west and south, in Syria and Asia Minor. See TURKESTAN.

TURMERIC, the tuberous rhizomes of a plant (*Curcuma longa*) of the ginger family. It is a perennial, native to southern Asia, and cultivated largely both there and in the Malayan Islands. The ovate, central tubers are known as "bulbs," or "round turmeric"; the more cylindrical, lateral ones, as "fingers" or "long turmeric." They are all hard and tough, brownish or yellowish-green outside and orange-hued, resinous and aromatic internally. The aromatic taste and odor are due to an oil called turmerol or turmeric-oil. Turmeric, ground into a powder, has been valued for centuries in Asia, and especially in India, as a carminative and aromatic-stimulant drug, an infusion of it in milk being a common remedy for colds; it is also applied externally as a cooling lotion for diseases of the skin and eyes. Its chief utility in India, however, is as a condiment and dye, it being the important yellow ingredient of curries and curry-powder, and yielding a beautiful, but fugacious yellow dye. White paper soaked with a tincture of turmeric changes to a reddish-brown color, drying out to violet when an alkali is added to it, so that a test-paper for alkalies is prepared from it called turmeric or curcuma paper. The plant itself has long, narrow sheathing leaves on the flower-stalk, which end in a leafy spike of yellow flowers. A species of *Canna*, cultivated in Sierra Leone, is the African turmeric, used by the natives there as a dye-plant. Bloodroot (*Sanguinaria canadensis*) and the yellowroot (*Hydrastis canadensis*) are also called turmeric and turmeric-root. The turmeric-tree is *Acronychia baueri*, of southeastern Australia, the bright-yellow inner bark of which yields a dye.

TURNBULL, Robert James, American publicist: b. New Smyrna, Fla., Jan. 1775; d. Charleston, S. C., 16 June 1833. He was educated in England, was admitted to the bar in 1794 and began practice in Charleston. In 1810 he retired to his estate and became active in the Nullification movement. He was a member of the free trade convention (1831–32), was a delegate to the South Carolina convention that passed the Nullification ordinance (1832) and joined the volunteers to oppose the constitutional government. His pamphlets written under the pseudonym of "Brutus" were collected and published in 1830.

TURNBULL, William, American engineer: b. Philadelphia, Pa., 9 Oct. 1800; d. Wilmington, N. C., 9 Dec. 1857. He was graduated at the West Point Military Academy in 1819 and entered the army as lieutenant of artillery. He was made assistant topographical engineer with the brevet of captain in 1832, and in 1843 was superintending topographical engineer on the Potomac aqueduct. He was made major in 1838, had charge of repairs to the Potomac long bridge (1841–43) and later was in charge of harbor improvement on the Great Lakes. He was brevetted colonel for services during the war with Mexico, and was afterward engaged in a variety of difficult engineering projects.

TURNER, tėr'nėr, **Charles Tennyson,** English poet: brother of Alfred Tennyson. See TENNYSON-TURNER, CHARLES.

TURNER, Charles Yardley, American artist: b. Baltimore, Md., 25 Nov. 1850; d. New York, 31 Dec. 1918. He studied in Paris with Laurens, Munkacsy and Bonnat. Was elected to the National Academy of Design; was member of the American Water Color Society, the American Etchers and the National Society of Mural Painters. Mr. Turner excelled as a mural painter. One of his pictures is in the courthouse at Baltimore and shows the burning of the steamboat *Peggy Stewart.* Other paintings are in New York galleries and elsewhere. Among his works familiar to many are the decorations in the rotunda of the Manhattan Hotel, New York. In the Metropolitan Museum is his 'Bridal Procession' and in the Union League Club, Chicago, is 'John Alden's Letter.' 'A Dordrecht Milkmaid,' in the Water Color Society exhibit in 1892, attracted much favorable attention, and then came perhaps the most noted of his canvases, 'Days That Are No More,' picturing a widow and a child on the stile of a churchyard. At the Buffalo Pan-American Exposition (1901) Mr. Turner was director of color; he was assistant director of decoration at the World's Columbian Exposition, Chicago, in 1893. In 1912 he became director of the Maryland Institute Schools of Art and Design at Baltimore.

TURNER, Ethel, pen name of MRS. H. R. CURLEWIS (q.v.).

TURNER, Fred, Australian botanist: b. Pontefract, England, 1856 He went to Australia in 1874, where he joined the staff of the Government Gardens at Brisbane and remained for five years, when he became botanist to the Department of Agriculture of New South Wales, and consulting botanist to the West Australian government. He traveled over 60,000 miles throughout Australia botanizing; made the study of botany popular in Australia and wrote interestingly on the subject for the press. He is the author of numerous works, many of which have been published by the government; translated into numerous foreign languages and republished at the expense of foreign governments. He is the holder of many medals and diplomas for economic botany. For several years he was engaged in the botanical survey of New South Wales. Among his published works are 'Grasses of New South Wales' (1890); 'Indigenous Forage Plants of Australia' (1891); 'Australian Grasses' (1895); 'West Australian Grasses' (1896); 'West Australian Salt Bushes' (1897); 'Suspected Poison Plants of New South Wales' (1890–1914); 'Noxious Exotic Weeds' (1890–1913); 'New Commercial Crops for New South Wales' (1890–1914).

TURNER, Frederick Jackson, American historian: b. Portage, Wis., 14 Nov. 1861. He was educated at the University of Wisconsin and took his Ph.D. degree at Johns Hopkins (1890), becoming professor of American history in the University of Wisconsin (1892–1910) and professor of history in Harvard the latter year. He was president of the American Historical Association (1910–11) and associate in the department of historical research of the Carnegie Institute (1916–17). He is author of 'Rise of the New West' (1906); 'Reuben Gold Thwaites' (1914), etc.

TURNER, Henry McNeal, American bishop of the African Methodist Episcopal Church: b. Newberry Court House, S. C., 1 Feb. 1834; d. 8 May 1915. He educated himself by dint of earnest perseverance and was licensed to preach by the Methodist Church South in 1853. In 1858 he transferred his membership to the African Methodist Church and studied for the classics, Hebrew and divinity at Trinity College. He was the first colored chaplain ever commissioned, and after being mustered out in 1868 was then commissioned chaplain of the regular army. He sat in the Georgia legislature in 1868 and 1870, and in 1880 became a bishop in his Church. He organized four annual conferences in Africa, was a prominent advocate of the return of his race to Africa and published 'Methodist Polity,' etc.

TURNER, Joseph Mallord William, English painter: b. London, 23 April 1775; d. Chelsea, 19 Dec. 1851. He entered the Royal Academy as a student, and after remaining there in that capacity for five years and working actively at his profession for another five, during which periods he sent to the exhibition no less than 59 pictures, he was elected in 1799 an associate of the Royal Academy. In the two following years he exhibited 14 pictures, and in 1802 was elected an academician. Until this date he had chiefly been known as a landscape painter in water-colors, but thenceforth he turned his attention to oil-painting, and in the ensuing half century produced at the Academy exhibitions upward of 200 pictures. In 1807 he was elected professor of perspective in the Royal Academy, and the following year appeared his 'Liber Studiorum' or 'Book of Studies,' which Charles Turner, Lupton and others engraved. Other works by him which were engraved are his illustrations of Lord Byron's and Sir Walter Scott's poems; Rogers' 'Italy' and 'Poems'; 'The Rivers of England'; 'The Rivers of France' and 'Scenery of the Southern Coast.' To enumerate the different paintings of Turner would be impossible. They have established him as the greatest of English landscape painters and earned for him the appellation of the "English Claude"; indeed many of his admirers pronounce him superior to the great French painter of that name. Among his more famous pictures reference may specially be made to his 'Kilchurn Castle'; 'Loch Awe'; 'The Tenth Plague of Egypt'; 'The Wreck of the Minotaur'; 'Calais Pier'; 'The Fighting Téméraire Tugged to her Last Berth'; 'The Grand Canal, Venice'; 'Dido and Æneas'; 'The Golden Bough'; 'Modern Italy'; 'The Fall of Carthage'; and 'The Building of Carthage.' In private life Turner was a man rather of reserved and unsocial manners, but the reports circulated of his parsimony and sullenness appear to have been quite untrue, and many instances are recorded of his liberal and generous acts both as a man and an artist. He never was married. By his will he bequeathed all his pictures, of which he had about 60 in his possession at his death, along with an immense number of engravings and sketches, to the na-

tion, on condition of a suitable building being erected within 10 years for their reception. They have been placed in the Turner Gallery, occupying two rooms in the National Gallery. He also intended a large part of his fortune to be devoted to the formation of a benevolent fund for artists, but this intention, though clearly enough expressed, was set aside by the lawyers because of the somewhat confused nature of his will. Turner owes his immense reputation largely to the brilliant advocacy of John Ruskin (q.v.) in his 'Modern Painters.' Mr. Ruskin divides his career, from an artistic point of view, into five periods: a period of development, three periods of greatness and one of decline. His development period ended with 1800. It includes these, among other works: 'A View of the Archbishop's Palace at Lambeth' (1790); 'The Pantheon the Morning after the Fire' (1792). His first style lasted from about the beginning of the century to about 1820, and in it he "labored as a student imitating various old masters." The principal pictures of this period are 'The Fifth Plague of Egypt' (1800); 'The Tenth Plague of Egypt' (1802); 'Kilchurn Castle' (1802); 'Calais Pier' (1803); 'The Shipwreck' (1805); and 'Dido building Carthage' (1815). The 'Liber Studiorum' also belongs to the period of his first style. His second style prevailed, according to Ruskin, from about 1820 to about 1835, and was characterized by freedom from mere imitation and by striving for beautiful, ideal effects. Among the works which illustrate it are the following: 'The Bay of Baiæ,' with 'Apollo and the Sibyl' (1823); 'Cologne' (1826); 'Dido directing the Equipment of the Fleet' (1828); and 'Ulysses deriding Polyphemus' (1829). During his third period, 1835–45, he produced many splendid works of marked individuality, but shallow critics began to ridicule him and his work, and full appreciation of his genius did not come until Ruskin entered the lists in 1843. The following represents his third style: 'Mercury and Argus' (1836); 'Snowstorm, Avalanche, and Inundation' (1837); 'Modern Italy' (1838); 'Ancient Italy' (1838); 'The Fighting Téméraire Tugged to her Last Berth' (1839), his best known picture; 'The Campo Santo' (1842); 'The Snowstorm' (1842); 'Peace — Burial at Sea' (1842); 'The Approach to Venice' (1843); and 'Rain, Steam and Speed' (1844). The remaining years of his life were years of decline, but his genius still asserted itself fitfully. The Metropolitan Museum and the New York Public Library have several good examples of the work of this artist. Consult Ruskin, 'Modern Painters,' biographies by Thornbury (New York 1862); Hamerton (Boston 1879); Monkhouse (New York 1882); Armstrong, Sir W., 'J. W. Turner' (New York 1901); Wornum, 'Turner Gallery' (1859); Wedmore, 'Turner and Ruskin' (2 vols., London 1900); Cook's Handbook to the National Gallery; Rawlinson, W. G., 'Turner's Liber Studiorum: Description and Catalogue' (2d ed., New York 1907); Finbery, A. J., 'Turner's Sketches and Drawings' (ib. 1910); Phythian, J. E., 'Turner' (ib. 1911); Wyllie, W. L., 'J. M. W. Turner' (ib. 1905). See also the article PAINTING for an indication of his position in the history of painting.

TURNER, Nat, negro slave, preacher and leader of the "Southampton Insurrection"; b. Southampton County, Va., 1800; executed at Jerusalem, Va., 11 Nov. 1831. A man of elementary education, but a preacher of natural ability and influence among the negroes, his mystical claims of hearing voices and seeing visions from childhood culminated in 1828 when he announced that a voice from heaven had declared that "the last shall be first"; that the negroes should rise and slay their enemies and gain freedom and control, when a sign should appear. The solar eclipse of February 1831 and subsequent unusual atmospheric conditions were accepted as the signal, and on Sunday night, 21 Aug. 1831, Turner and seven companions murdered his master and five members of the family in their beds. With their band increased to 53 members, the negroes massacred 24 children, 18 women and 13 men of white blood before noon of the following day, when they were dispersed by a party of white men who had hastily gathered for defense. The criminals were subsequently hunted down and Turner escaped capture until 30 October. Tried and condemned, 17 of the band, including Turner, were hanged. The remainder received other sentences, as evidence showed that they acted under life or death compulsion. In other instances, at the risk of their lives, faithful slaves successfully defended their masters and families from slaughter. Pro-slavery advocates irrationally attributed the insurrection to the work of the abolitionists. Stricter slave codes were enacted, and the liberation movement received a serious setback. Consult Drewry, W. L., 'The Southampton Insurrection' (Washington 1900).

TURNER, Ross Sterling, American artist: b. Westport, Essex County, N. Y., 29 June 1847; d. 12 Feb. 1915. He adopted the profession of an artist in 1873 and studied in Germany and Italy. Among his notable pictures are 'A Small Court, Mexico'; 'El Jardin Modesto'; and 'A Bermuda Wedding.' He is the writer of 'Water Colors'; 'Art for the Eye — School Room Decorations', etc.

TURNER, Sharon, English historian: b. London, 24 Sept. 1768; d. there, 13 Feb. 1847. After a successful career as a London attorney he retired from practice in 1829 and devoted himself to literary pursuits. He is best known by his 'History of the Anglo-Saxons' (1799–1805; 7th ed., 1852), long a standard authority. His other works include 'History of England during the Middle Ages' (1814–23; 7th ed., 1853); 'Modern History of England,' comprising 'The Reign of Henry VIII' (1826); and 'The Reigns of Edward VI, Mary and Elizabeth' (1829); 'Sacred History of the World as Displayed in Creation and Subsequent Events to the Deluge' (1832; 8th ed., 1848), etc.

TURNER, Thomas, American naval officer: b. Washington, D. C., 23 Dec. 1808; d. Glen Mills, Pa., 24 March 1883. He entered the navy in 1825, served on the *Columbia*, flagship of the East India squadron, in 1838–41, and participated in the destruction of the Malay pirate towns, Mucke and Quallat Rattoo, Sumatra, in 1839. He was commander of the *Fredonia* in the Gulf squadron in 1847, commanded the

Reefer in the assault upon Tuspan in April 1847, and in 1855 was promoted commander. In 1858–60 he was in command of the *Saratoga* in the Home squadron, and in the latter year captured the ships *Miramon* and *Marquis de Habana,* which were being used by the Mexican revolutionary party to blockade the port of Vera Cruz. At the outbreak of the Civil War he was assigned to command *New Ironsides* in the South Atlantic squadron, was promoted commodore in 1862 and took an important part in the assaults on the forts of Charleston, S. C., in 1863. He became rear-admiral in 1868, commanded the Pacific squadron in 1868–70, and in the year last named was retired, after 45 years of active service.

TURNER, Sir William, English anatomist: b. Lancaster, 1832; d. 1916. He received his general education in private schools and began the study of medicine in Saint Bartholomew's Hospital, graduating with distinction in the University of London in 1857. He became a member of the Royal College of Surgeons in 1853 and in the following year was appointed demonstrator in anatomy in the University of Edinburgh. In 1867 he succeeded John Goodsir as professor of anatomy. This post he resigned in 1903, when he was elected principal of the university. After 1873 he represented his university on the General Medical Council, of which he became president in 1898. In 1886 he was knighted. He presided over the meeting of the British Association at Bradford in 1900 and delivered an address on the progress of the cell-theory in biology. He examined in anatomy on behalf of the universities of Oxford, London and Durham, and lectured before the Royal College of Surgeons. He was one of the founders, and from 1866 to 1894 was joint editor of the *Journal of Anatomy and Physiology,* and contributed many papers to the transactions of learned societies. He published 'An Introduction to Human Anatomy' (1875); 'Lectures on the Comparative Anatomy of the Placenta' (1876); and an 'Atlas of Human Anatomy and Physiology.'

TURNER, William Wadden, American philologist: b. London, England, 23 Oct. 1810; d. Washington, D. C., 29 Nov. 1859. In 1818 he came to New York, was given a public school education and became a printer. At 26 he was a master of modern languages and Hebrew, and later secured a knowledge of Arabic, Sanskrit and other Asiatic tongues. He printed a number of works. In 1842 he was elected professor of Oriental literature in Union Theological Seminary and held the position until 1852, when called to the library of the patent office in Washington.

TURNER PRINTS. See Engravings.

TURNER FALLS, Mass., village in Franklin County, on the Connecticut River, and on the New York, New Haven and Hartford and the Boston and Maine (Fitchburg) railroads, about 35 miles north of Springfield and three miles northeast of Greenfield, the county-seat. The village is in an agricultural section and has considerable manufacturing interests. The long bend here in the river is cut off by a canal three miles long, which, with three falls, furnish extensive water power. The chief manufactures are cutlery, paper, leather, foundry and machine-shop products and cotton goods. The village has a high school, public and parish schools and a public library. Turner Falls is the largest village in the town of Montague (q.v.). Pop. (included in that of the town) about 6,866.

TURNER'S GAP, Battle of. See South Mountain, Battles of.

TURNER'S REBELLION. See United States, Wars of the; Nat Turner's Rebellion.

TURNEY, tėr'nĭ, **Peter,** American jurist, son of Hopkins Lacey Turney: b. Jasper, Tenn., 22 Sept. 1827; d. Winchester, Ky., 19 Oct. 1903. He was admitted to the bar in 1848, practised law at Winchester until the secession of the Southern States, which he actively promoted, and then entered the Confederate army, in which he served throughout the war. He resumed his practice at Winchester after the war, was a justice of the Supreme Court of the State in 1870–86, chief justice in 1886–93, and in 1893–97 served as governor.

TURNIP, a popular name for two closely related biennial herbs of the family *Brassicaceæ.* The common turnip (*Brassica rapa*) has a flattened white-fleshed, tuberous root crowned by a compact tuft of thin green hairy leaves from the centre of which, during the second season, a flower-stem rises about 18 inches and bears numerous yellow flowers. The Swedish turnip, rutabaga or baga (*B. campestris*), has a more globular yellow-fleshed root with a more or less distinct leafy neck and glaucous bluish hairless cabbage-like leaves. The flowers are also yellow. The former has also a tap-root with few fibres; the latter has a large number of fibrous roots not only from the main tap-root but from the base of the tuberous part. Neither of these species is definitely known in the wild state, but they are supposed to be natives of eastern Europe or adjacent parts of Asia. They have been cultivated for centuries as food for man and beast, the common turnip for early use in spring and autumn and the rutabaga more as a winter vegetable or stock food. In many places they have run wild and are occasionally known as charlock. When wild they soon lose the tuberous root.

Except in season of sowing, the cultivation of both species is similar. The common turnip is a quick-growing plant which is usually sown as soon as the soil can be worked in the spring or during midsummer. The first sowing produces roots for late spring and early summer use; the last, for autumn consumption. The rutabaga is generally grown as a full season crop, the seed being sown in late spring. It is much richer in flavor than the common turnip. Like other root crops both these plants succeed best upon deep, rich, well-drained light loamy soils free from stones and other obstructions. The seed is sown in drills about 18 inches apart and the plants thinned to stand about eight inches asunder. The late crop is often sown broadcast, particularly where beef cattle are kept, since the animals may be turned upon the field to browse after the larger roots have been gathered for storing or sale. For success in such practice, however, the supply of moisture in the ground must be abundant,

and the soil must be in the highest possible state of tilth before the sowing of the seed because no cultivation can be given during the growing season. When sown in drills clean cultivation must be given until the leaves meet between the rows and completely shade the ground. Under favorable conditions and good cultivation the yield has exceeded 1,000 bushels to the acre, but under ordinary management half this amount is nearer the average. The early crop is often sold in bunches; the late, by measure. The only insects that are occasionally troublesome are the maggot and the flea-beetle. The former may be avoided by judicious rotation, turnips never being planted oftener than once in three years upon land which has been occupied by a cruciferous crop. The flea-beetles may be repelled by tobacco dust, Bordeaux mixture, etc.

TURNPIKE, a gate that is set across a road and is watched by a person appointed for the purpose in order to stop carriages, carts, wagons, etc., and sometimes travelers, till toll is paid, for the cost and upkeep of the road. Such roads are called turnpike-roads, or simply turnpikes, and formerly were very numerous in Great Britain, but latterly tolls on roads have been almost entirely abolished. See ROADS AND HIGHWAYS.

TURNPIKE GERANIUM. See GOOSEFOOT.

TURNSPIT, a small dog, somewhat like a dachshund, used in old times, in the kitchens of great houses, to turn the spits or jacks upon which meat was roasted before an open fire, the dog traveling in a small treadmill geared to the spit. The breed is now practically extinct.

TURNSTONE. See BRANT-BIRD.

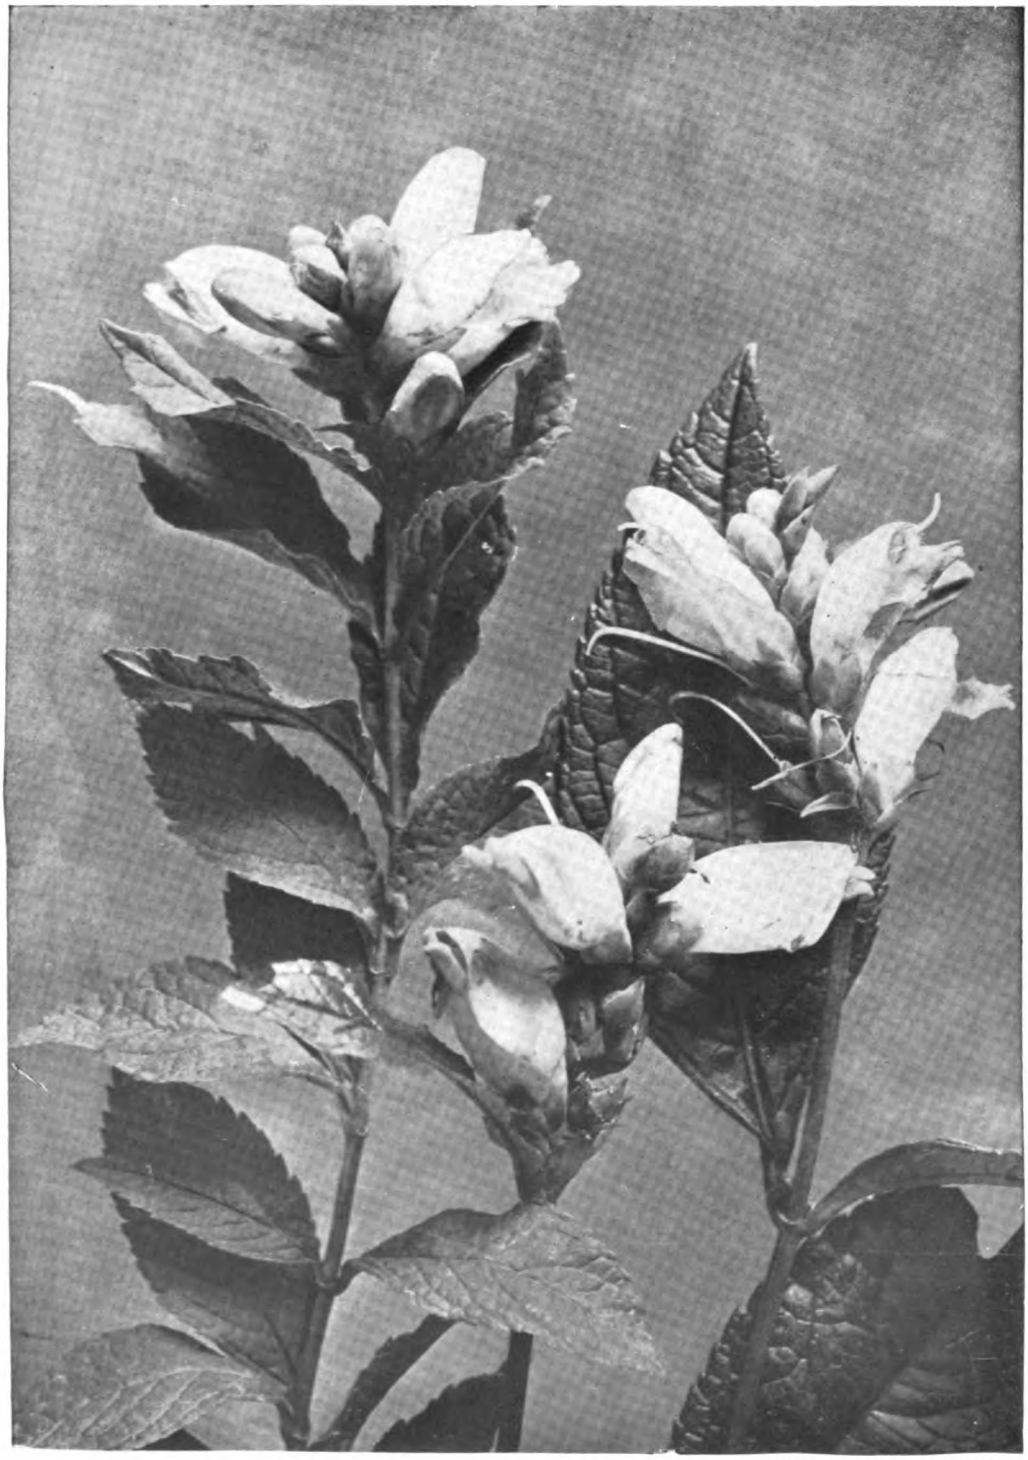
TURPENTINE, a resinous juice, oleoresin, extracted from several trees belonging to the genus *Pinus*. The common American turpentine of commerce comes from the *Pinus palustris*, which grows abundantly in the Southern States. When first extracted it is crude or common turpentine, varying from 75 to 90 per cent of resin and 25 to 10 per cent of oil. Crude turpentines are named from the trees or the territory from which they are taken, as Aleppo turpentine, from the Aleppo pine; American turpentine, from *Pinus palustris;* Bordeau turpentine, from the seaside pine (*P. pinater*); Canadian turpentine, from the balsam-fir; Carpathia turpentine, from the Swiss pine; Hungarian turpentine, from the Mugho pine; also white turpentine, from the long-leaved Carolina pine. The Pistacia tree also yields an excellent turpentine and is sometimes called the turpentine tree, or terebinth. This is believed to have been the original source, the trees being plentiful in the island of Chios. To obtain the oil of turpentine the juice is distilled, usually with water. (See TURPENTINE OIL). Oil or spirit of turpentine, often called simply turpentine, and also "turps," is colorless and is employed extensively in medicine, both internally and externally, and it is also widely used in the preparation of paints and varnishes.

The Box Method.— Prior to 1901, turpentine gathering, as conducted in the United States, was needlessly destructive of the forests and needlessly wasteful of the product. The method, under the box system universally employed, was to chop into the base of the tree itself a cup-like cavity, the sole purpose of which was to receive the resin which flowed from a scarified face of the trunk above it. The box itself does not add to the flow of turpentine; on the contrary, experiment has proved that it diminishes the flow. It is an unnecessary wound driven into the body of the tree at its most vital spot, both weakening its vigor and lessening its power to support the strain of the wind. At the same time it opens the trunk to disease and provides a storehouse of combustibles against the coming of the forest's great enemy — fire. A forest which has been heavily turpentined by this method has before it only decay and death. Until recently the destructive methods in use have been regarded with entire indifference in the regions affected. This has been due to the low valuation of timber throughout the turpentine belt and to the popular belief that the pine forests of the Southern States were inexhaustible.

The Cup System.— In 1901 Dr. Charles H. Herty, of the Bureau of Forestry, after numerous experiments, discovered a new way of extracting turpentine by using earthen pails or cups, not unlike the method of obtaining maple sap. The discovery has resulted in a complete change of methods by turpentine operators all over the South. In a bulletin published in 1902 by the Bureau of Forestry, the claim was made that the experiments with the new cup and gutter system of turpentining had resulted in an increase over the old boxing system of 23 per cent in the amount of the product extracted. This figure was raised in 1903 to more than 36 per cent. The economic saving of this new discovery is enormous. It not only causes a great increase in the amount of turpentine produced, but it is a most important factor in saving the pine forests of the South. Trees from which turpentine has been extracted by the old method soon die from the wounds inflicted on them. The cup and gutter system, on the other hand, is not fatal to the life of the tree and does very little damage to the timber.

The experiments during 1903 have abundantly justified the claim made that the box is an "unnecessary wound," for the cup system has proved efficient in the hands of the regular turpentine labor, while the increased profits under this improved system are sufficient to warrant its adoption by any turpentine operator, regardless of all questions connected with the future of the naval-stores industry. Recent experiments in the distillation of wood have demonstrated that a vast amount of turpentine may yet be obtained from the fallen pines of the South, which are preserved by their content of resin and turpentine. This product is sometimes called artificial turpentine. For statistics and other information concerning the turpentine industry see the article NAVAL STORES. See also ROSIN.

TURPENTINE OIL, the volatile oil or spirit obtained by distilling crude turpentine, the latter being obtained from coniferous trees by incision through the bark or wood. When crude turpentine is distilled there results resin, a solid, and the oil of turpentine, a liquid, which when pure is clear and colorless. It consists chiefly of an essential hydrocarbon oil ($C_{10}H_{16}$),



Photograph by J. Horace McFarland Co.

CHELONE (TURTLE-HEAD)

and the resin, colophony. It is possessed of a penetrating, peculiar odor and a pungent, bitter taste. The various oils display marked diversities in physical properties according to their sources. They are insoluble in water, slightly soluble in aqueous alcohol and miscible in all proportions with absolute alcohol, ether and carbon disulphide. They are solvents for iodine, sulphur, phosphorus, resins and fixed oils. The two principal varieties are derived from the sap of the *Pinus maritima*, or the French maritime pine, and from the long-leafed pine of the Southern States of the United States. The former has a specific gravity of 0.864, boils at 161° and turns the plane of polarization to the left; the latter has the same specific gravity and boiling point, but turns the plane of polarization to the right. Both oils absorb oxygen from the air and acquire powerful oxidizing properties for the probable formation of an organic peroxide ($C_{10}H_{14}O_4$). Turpentine absorbs chlorine with such energy as sometimes to set it on fire. Turpentine oil is of great importance in the arts, and is especially employed for giving consistency to oil paints and varnishes, conferring on them drying properties. In pharmacy, in small doses it is absorbed and acts as a stimulant, antispasmodic and astringent. It produces diuresis, and communicates to the urine passed a smell like that of violets. It can arrest hemorrhage in the capillary vessels. It is generally administered as an enema to destroy tænis, ascarides, etc., in the intestines. Applied externally, it is a powerful rubefacient. Chian turpentine, the product of the terebinth tree, has latterly been successfully employed in cancer.

TURPENTINE VINE. See PISTACHIA.

TURPIN, tėr'pĭn (Fr. tür-păn), or **TYLPINUS,** French prelate: d. 2 Sept. 800. He was archbishop of Rheims and reputed author of a Latin narrative of Charlemagne's wars against the Saracens. There are indications that the work was written in the 12th century, perhaps by Pope Calixtus II. There are editions by Ciampi (1822) and Reiffenberg (1836). Consult Paris, 'De Pseudo-Turpino' (1865); id., 'Histoire poétique de Charlemagne' (ed. by Paul Meyer, Paris 1905); Potthast, August, 'Bibliotheca Historica Medii Ævi' (Vol. II, Berlin 1896).

TURPIN, Richard (known as "DICK TURPIN"), English highwayman: b. Hempstead, Essex. He began life as a butcher's apprentice, was detected in cattle-stealing, fled and joined a band of thieves, with whom he engaged in various acts of depredation and brutal crime. He was captured at York and hanged for murder. His lawless daring made his name a byword, but he has also been decked in the colors of heroism through the ascription to him of generous qualities which there is no evidence to show that he possessed. He is the hero of Harrison Ainsworth's 'Rockwood' (1834).

TURQUOIS, tėr-koiz', a mineral whose name (often spelled "turquoise") alludes to its coming into the European market through Turkey. It is a hydrous phosphate of aluminum, containing a small amount of copper, to which its color is due. It has been a favorite gem in the Orient, from the earliest times, appearing in Egyptian jewelry of extreme antiquity. Turquois does not crystallize, but forms little veins and nodules in a trachytic igneous rock. Its hardness is 6, its specific gravity from 2.6 to 2.8, lustre somewhat waxy and its color varies from dull green to beautiful pale blue. In modern jewelry, only the fine "robin's-egg" blue stones are prized; these occasionally turn green because of the gradual drying out of the water which they contain; heating or exposure to the weather always produces this change. The chief turquois mines, near Nishapur, in Persia, have been worked for many centuries; it has also come from the Sinaitic peninsula, which was probably the ancient Egyptian source. The Persian yield has been failing recently, under crude and primitive methods of working; but a number of American localities have been discovered which are now furnishing a large part of the world's supply. All these mines were formerly worked by Indian or Aztec peoples, some of them very extensively, though only with fire and stone tools, which latter are always present. In some cases, traditions still linger among the Indians, and the stone is held sacred to Montezuma and his people. It figures largely in the Spanish records of the conquest of Mexico, and was in part the highly prized "chalchihuitl" of the Mexicans; though in central and southern Mexico this stone was not turquois but green jade. The chief locality is near Los Cerillos, New Mexico; it is also mined at several other points in New Mexico, Arizona, Nevada and California. A substance often used in place of true turquois is the so-called bone-turquois or ondontolite, which is fossil bone colored blue by phosphate of iron. It is easily distinguished under the microscope by its structure, and by its not yielding a blue color with hydrochloric acid and ammonia. Turquois in the natural rock has recently been very extensively cut into gem stone and sold under the name of "turquois matrix." Consult Pogue, J. E., 'The Turquoise; Its History, Mineralogy, Geology, etc.' (206 pages plates Memoirs National Academy of Science, Vol. XII, pt. 2).

TURRET, *in architecture,* a kind of small tower. Turrets are chiefly of two kinds, such as rise immediately from the ground, as staircase turrets, and such as are formed on the upper part of a building by being carried up higher than the rest. In modern naval architecture, the term is given to a revolving tower usually of armor plate in or on top of which the ship's guns are mounted.

TURTLE CREEK, Pa., borough in Allegheny County, on the Pennsylvania and the Union railroads, 12 miles southeast of Pittsburgh. It has a Carnegie library and a large technical school, and the Westinghouse Electric and Manufacturing Company has a big plant there. Pop. about 5,000.

TURTLE-DOVE. See DOVE.

TURTLE-HEAD. The popular name given to *Chelone barbata* and *Chelone campanulata* plants of the natural order *Scrophulariaceæ* now classed with the Pentstemons (q.v.). They are distinguished by leaves of a leather-turtle appearance whence the designation.

TURTLE TRIBE. See UNAMI.

TURTLES, TORTOISES and **TERRAPINS,** members of the reptilian order *Testudinata* or *Chelonia* (q.v.). To all of the marine and some of the fresh-water species, especially those of large size, the name "turtle" is applied; most of the smaller pond and marsh dwellers are "water-tortoises," a few being designated as "terrapins," while the terrestrial ones, whatever their size, are properly "land-tortoises." About 300 living species, most of them inhabitants of fresh waters, have been described, but the group has steadily declined since Eocene times, and many ancient families are entirely unrepresented in the modern fauna. Tortoises are especially numerous in warm climates, and none extend into the Arctic regions. The marine forms are pelagic and wide-ranging. The various members of this group exhibit considerable diversity in habits and structure, and have been arranged (see CHELONIA) in four sub-orders and numerous families, of which three sub-orders and seven families are represented in the North American fauna.

Of the sub-order *Athecæ* and family *Dermatochelydidæ* the huge leather-turtle (q.v.), the largest of all modern turtles, occasionally appears on our coast. The *Trionycholidea* with the single family *Trionychidæ,* or soft-shelled turtles, are found in the fresh waters of Africa, Asia and North America. They have the plastron and carapace incomplete and covered by a leathery skin; the neck is very long and flexible, and though folding vertically cannot be retracted entirely within the shell; the head is small and elongated with a slender snout, at the tip of which are the nostrils; the feet are broadly webbed, with long straight claws on some of the toes. *Amyda mutica* has the upper jaw serrate and the carapace without tubercles. It is found in the region of the Great Lakes and the Ohio River. *Aspidonectes spinifer* has the cutting edge of the upper jaw smooth and the margin of the carapace with tubercles. It is abundant throughout the upper Mississippi Valley and particularly in the sluggish streams emptying into the Great Lakes. Closely related species are found southward. The soft-shell turtles are strictly aquatic, leaving the water habitually only in the spring, when about 50 spherical hard-shelled white eggs are deposited in an excavation above the level of the water. They spend much time buried in the mud at the bottom, either entirely concealed or with the head protruding from a hole. They breathe by raising the nostrils to the surface, or, if in water too deep, by means of a thick growth of vascular papillæ in the pharynx over which a current of fresh water from the nostrils continually passes. Strictly carnivorous, they feed upon all kinds of fish, frogs, mussels, snails and insects which come within reach of their ravenous jaws and which they seize with remarkable suddenness. They are powerful swimmers.

The order *Pleurodira* includes three families of recent and several of extinct turtles, the former being confined to the fresh waters of South America, Africa and Australia. The tartaruga of the Amazon is of great commercial importance. Unlike most turtles of this group they are said to be largely vegetarian, which probably accounts for the great value placed upon their flesh and fats. During the months of September and October vast numbers leave the water at about midnight to deposit their eggs in holes on the higher ground. Two related genera are found in Africa. The family *Chelydidæ* is confined to South America and Australia. The matamata (*Chelys matamata*) is common in Cayenne. Its length when fully grown is about three feet. It is remarkable in many ways; its snout is prolonged as in *Aspidonectes* and the head and neck are covered with tufts of cutaneous outgrowths which probably assist in the concealment of the animal in the thick aquatic vegetation among which it lives. It is carnivorous.

To the *Cryptodira* belong the great majority of living turtles and tortoises. This sub-order includes 10 or 12 families, seven of which have recent representatives. The *Cheloniidæ* includes the sea-turtles, in which the limbs are flat, scaly, inflexible paddles and the heads quite incapable of retraction within the shell. Only four genera and about seven species are known, all widely distributed. The three Atlantic species all occur on our shores more or less frequently. The best-known one is the green turtle, whose flesh is so highly esteemed in soups, etc. This species (*Chelone midas*) is the largest of sea-turtles, and reaches in some cases a weight exceeding 1,000 pounds. It occurs in all parts of the world when the water is not very cold, but most numerously about tropical archipelagoes. As with the other large sea-turtles, the most numerous catch is made when the females come on shore at egg-laying time, on moonlight nights in summer. Their retreat is cut off and the turtle turned on its back. When once in this position these turtles are unable to right themselves. They can endure many weeks without food and water, and hence can be transported great distances on seas in the hold of ships. Before the days of refrigerated meat they served as a welcome diet for sailors; and on some of the Pacific islands these and other large turtles were wholly exterminated by reckless slaughter. The green turtles feed on the roots of the eel-grass, and, betrayed by the floating tops of the grass, are sometimes taken in nets while feeding. The principal catch for the American market is now made in the neighborhood of the Florida reefs, where it forms a regular business with many boatmen. Their catch is largely made by spearing.

Another large and valuable turtle is the hawksbill (q.v.), which furnishes tortoise-shell (q.v.). A third species is the loggerhead (*Thalassochelys caretta*), which is much more frequently taken on the coast of the Middle and New England States than either of the others. It may be distinguished from the green turtle by the thin non-imbricated plates of the carapace, by having the central scale on the top of the head surrounded by a circle of more than 12 small scales, while the green turtle has seven; and by having two, instead of one, claws on the feet. This species reaches a large size, up to 500 pounds, and is carnivorous. It has no commercial value, but is sometimes sold as the green turtle.

A strictly American family (*Chelydridæ*) is that of the snapping-turtles (q.v.), including two well-known species of some commercial importance.

L. Leath, Printer & Typ

TURTLES

1. **Leather-back** Turtle. 2. Hawksbill, or Tortoise-shell Turtle. 3. Long-necked Turtle. 4. Matamata
5. Elephant Land-tortoise. 6. Wood-tortoise. 7. Snapping-turtle.

Numerous species of small or medium-sized pond, swamp and land tortoises belong to the families *Kinosternidæ* and *Emyidæ*. Of the first the well-known musk-turtle or stink-pot of boys (*Aromachelys odoratus*), found in every pond in the Eastern States, is an example. The diamond-back (q.v.) (*Malaclemmys centrata*) of the Atlantic salt-marshes, the red-bellied terrapin (*Pseudemys rubriventris*), the painted turtle (*Chrysemys picta*) and the speckled tortoise (*Clemmys guttatus*), three common pond-turtles of the East, the last two being familiar to every fisherman, *Clemmys muhlenbergi*, a less common species distinguished by its dull brown shell and a yellow blotch on each side of the neck, and found along meadow streams, and the map-turtle (*Graptemys geographicus*), chiefly of the Mississippi Valley, and distinguished by the yellow streaks and irregular lines which everywhere mark the shell and skin, all belong to the *Emyidæ*, which also includes the familiar land tortoise (q.v.), or box tortoise (*Terrapene carolina*) and numerous other species.

Of the true land tortoises (q.v.) (*Testudinidæ*), the gopher turtle (*Gopherus polyphemus*) of the Southern States, the European land tortoise (*Testudo græca*) and the gigantic Gallapagos tortoises (*Testudo*) may be mentioned. See LAND TORTOISE.

I and II (Boston 1857); Boulenger, E. G., 'Catalogue Chelonians British Museum' (London 1889); id., 'Reptiles and Batrachians' (New York 1914); Hoffman, in Brown's 'Thierreichs' (Leipzig 1890); Taylor, 'Box Tortoises of North America' (Proceedings United States National Museum, Washington 1895); Gadow, 'Cambridge Natural History,' Vol. VIII (London 1901); True, 'The Useful Aquatic Reptiles and Batrachians of the United States' (Washington 1884); Williston, S. W., 'Water Reptiles of the Past and Present' (Chicago 1914). On fossil species consult Hay, O. P., 'Fossil Turtles of North America' (Washington 1908).

TUSAYAN, too-sä-yän', an ancient "province," comprising the tribal range of the Hopi or Moqui Indians of northeastern Arizona, which was first visited by Pedro Tovar and Juan de Padilla, of the expedition of Coronado, in the summer of 1540. It comprised seven villages or pueblos, probably all of which have since been abandoned and new ones built on near-by sites. Between the year named and 1583 two of the villages became depopulated, for in the latter year Antonio de Espejo visited the province of "Mohoce," consisting of the five villages of Shumopovi, Mashongnovi, Walpi, Oraibi and Awatobi, all but the last of which (which was destroyed about the year 1700) are still names of their present-day towns. In addition there are Shipaulovi, Sichumovi and Hano, which have been established in comparatively recent times, the last by a colony of Tanoan Indians from the Rio Grande in New Mexico. The Hopi Indians are peaceable, derive their subsistence through cultivation of the sandy soil and making excellent basketry and pottery. They still perform many aboriginal rites and ceremonies, the most celebrated of which is their snake dance, in which live rattlesnakes and other serpents are used. Their villages are all situated on lofty mesas, and their houses are generally similar to those of the other Pueblo Indians (q.v.). The Spaniards established missions among them as early as 1629, but they never took kindly to Christianization, and in 1680 murdered their Spanish priests. Henceforward little effort was made to convert them, but in recent years schools have been established in their midst by the United States government and an effort made to teach them the white man's ways, sometimes force being used to overcome their conservatism. The Hopi are kind, hospitable and industrious and have been regarded by ethnologists as the most primitive Indians within the United States. They number 1,841. Oraibi in the Moqui Reserve, Ariz., is their largest pueblo.

TUSCALOOSA, tŭs-kạ-loo'sạ, Ala., city, county-seat of Tuscaloosa County, on the Black Warrior River and on the Alabama Great Southern Railroad, about 52 miles southwest of Birmingham and 90 northwest of Montgomery. It was formerly the capital of the State (1826–46). It is in an agricultural region in which are grown large quantities of cotton. Extensive coal fields are in the vicinity. The chief manufacturing establishments are cotton gins, cotton compresses, flour mills, machine shops, iron smelters, coke ovens, lumber mills and creameries; coal mining and stock-raising contribute to the prosperity of the city. The principal public buildings are the courthouse, the Alabama Insane Hospital, the churches and schools. The educational institutions are Oak City Academy (Baptist), and Stillman Institute (Presbyterian), both for colored students, University of Alabama founded in 1831, University High School, a public high school, the Tuscaloosa Female College (Methodist Episcopal), Central Female College, Institute for Training Colored Ministers (Presbyterian), public elementary schools and libraries. Pop. about 12,000.

TUSCANY, tŭs'kạ-nĭ (Italian, TOSCANA, tôs-kä'nä), Italy, a compartimento, or territorial division, bounded by the divisions of Liguria, Emilia, Marches, Umbria and Rome, and on the west by the Ligurian and Tyrrhenian seas. It consists of the provinces of Arezzo, Florence, Grosseto Livorno (Leghorn), Lucca, Massa e Carrara, Pisa and Siena, with a combined area of 9,304 square miles. A number of islands off the coast form the Tuscan Archipelago. The greater part of the surface is mountainous with some enclosed river plains in the interior at Florence and Arezzo. Along the coast are the low, marshy and unhealthful regions of the Maremme. The principal rivers are the Arno, Cecina, Serchio and the Ombrone. The mineral wealth is very extensive, the chief products being iron, copper, mercury, lignite, fine Carrara marble, salt, boracic acid and sienna earths. The soil in the valleys is fertile, producing wheat, corn, grapes, olives, tobacco, chestnuts and flowers. The industries are very active and extremely varied. The capital is Florence, and the chief port is Leghorn. For ancient history and archæology see ETRURIA. After the fall of the Western Empire, Tuscany passed through various hands and

was finally made a duchy under the Lombards. In the 12th and 13th centuries it was broken up into a number of small republics, among which Florence held the leading place, and later it was reunited under the dukes of Florence, the Medici. After the extinctions of the Medici family it passed to the house of Lorraine, under which it remained, with an interruption at the time of Napoleon (see ETRURIA, KINGDOM OF), until it was annexed by Sardinia in 1860. It then became, with Sardinia, a part of the kingdom of Italy. See FLORENCE; AREZZO; PISA and appended bibliographies. Consult Cruickshank, A. M., 'Smaller Tuscan Towns' (New York 1912); Hewlett, M. H., 'Earthwork out of Tuscany' (ib. 1911); Hutton, Edward, 'Siena and Southern Tuscany' (ib. 1910); Seignobos, Charles, 'Political History of Europe since 1814' (English trans., New York 1900); von Reumont, Alfred, 'Geschichte Toscanas seit dem Ende des florentinischen Treistaates' (3 vols., Gotha 1876–77).

TUSCARAWAS, tŭs-kạ-râ'wạs, a river of northeastern Ohio; it unites with the Mohican and forms the Muskingum (q.v.). It is about 126 miles long. Massillon is the chief town on the river.

TUSCARORA, tŭs-kạ-rō'rạ (sig. probably «Indian-hemp gatherers»), a tribe of the Iroquoian stock of North American Indians, which, when first known to the whites, lived on the lower Neuse River and its tributaries, the Trent and the Contentnea, the Tar and Pamlico rivers, comprising the territory south of the present Raleigh, N. C. In 1711 they numbered about 4,000, in 15 towns. As the white settlers of North Carolina took from the Indians such lands as they needed, and as they also kidnapped young Indians for purposes of slavery in the West Indies and in the New England colonies, a large portion of the Tuscaroras, in 1711, incensed to bitter hatred toward the whites, formed with neighboring tribes a conspiracy to destroy all the settlers. The war which ensued lasted two years. On 26 March 1713 the hostile Tuscaroras were driven into a fort on Neuse River, where, after a severe conflict, they were defeated with a loss of 800 prisoners. Thus broken in power, the remnant of the hostiles migrated northward and in 1722 were adopted into the League of the Iroquois or Five Nations, in New York, forming the Sixth Nation. In the American Revolution the Tuscaroras espoused the cause of the colonists. They now number about 350 in Lewiston, New York, and 350 on the Six Nations reserve, Grand River, Canada. Neither portion retains distinctive pagan rites, and on the whole they are more progressive than their Indian neighbors.

TUSCULUM, tŭs'kū-lŭm, Italy, an ancient city of Latium, 15 miles south of Rome in the Alban Hills. Tradition has it that Tusculum was founded by Telegonus, son of Odysseus and Circe. Subsequently its relations with Rome were cordial, and bestowed upon it the right of citizenship. In the Middle Ages it became the seat of a powerful family of counts. In the 12th century it was destroyed by the Romans, whereupon the inhabitants built a new town in the vicinity — Frascati. Its beautiful location attracted many wealthy Romans, who established villas in the district. Distinguished among its residents were Lucius Crassus, the orator; Pompey, Hortensius, Lucullus, Scarus, Brutus, Cæsar and Cicero. This city existed until 1191 when the Romans destroyed it. The *Tusculanæ Disputationes* were written here. An ancient amphitheatre, theatre and fragments of the city walls belonging to the ancient city have been excavated. See FRASCATI.

TUSCUMBIA, tŭs-kŭm'bĭ-ạ, Ala., city, county-seat of Colbert County, on the Tennessee River, and on the Southern, the Northern Alabama and the Louisville and Northern railroads, about 174 miles northwest of Montgomery, and four miles below Florence, which is on the opposite side of the river. It was settled in 1812 and was incorporated in 1818. Tuscumbia is in a beautiful valley surrounded by hilly, almost mountainous land; the soil is fertile, the rainfall medium and distributed throughout the year, and the temperature favorable to agriculture and fruit-raising. The chief manufactories are railroad shops, agricultural-implement works, cotton gins and flour and feed mills. Pop. 3,500.

TUSK-SHELL. See DENTALIUM.

TUSKEGEE, tŭs-kē'gē, Ala., city, county-seat of Macon County, on the Tuskegee Railroad, a branch of the Western Railway of Alabama, 45 miles northeast of Montgomery. It was first settled in 1780 by Indian traders, was incorporated as a borough in 1800, and as a city in 1820. It is the centre of a fertile cotton-raising region; contains cottonseed-oil mills, cotton ginneries, brick kilns and saw-mills. It is also a pleasant winter resort. It is widely known as the seat of the Tuskegee Normal and Industrial Institute (q.v.), established in 1881, and is also the seat of the Alabama Conference Female College, Methodist, established in 1855. The city government is vested in a mayor and a council of six members. Pop. about 3,000.

TUSKEGEE NORMAL AND INDUSTRIAL INSTITUTE, a negro educational institution established by negroes in Tuskegee, Ala., for the education of students of their own race. The school was called into being by an act of Congress, and was opened in 1881 under the official name of Tuskegee State Normal School, and two years later this designation was changed to the present name. The growth of the institution was rapid and the attendance had reached near 2,000 in 1917. In this school have been trained many of the noted negro leaders of the country. Andrew Carnegie gave the college $600,000; and other gifts have raised the endowment fund to over $2,000,000 with the prospect of considerable additional funds in the near future. Tuskegee Institute possesses over 100 buildings, close upon 20,000 acres of public lands and a library of over 20,000 volumes, together with extensive modern school equipments. The faculty and office staff number close upon 200 employed in the home work of the college and in extension teaching; and the work which they are called upon to do is extensive, varied and far-reaching, embracing as it does the studies of the common school, the industrial school and the Bible-training institute and theological

seminary. Industrial training is one of the great features of the school; but it is not sufficient unto itself, since industrial instruction always goes hand in hand with the other educational work of the institute. The school curriculum includes day and night sessions, the latter being intended for students too poor to pay their way through college. Considerable stress is placed upon the teaching of the mechanical industries, and this department of the college covers everything from electrical engineering to shoemaking and the commoner trades of life. Attention is also paid to the industrial education of women in line with their lives. The extension work of the college, which is carried on through the Tuskegee Negro Conference, is largely directed to practical and industrial ends, in which agriculture receives special consideration. The name of Booker T. Washington (q.v.), its president until 1915, was as well known as the institute. Consult Washington, B. T., 'Up from Slavery' (1900); 'Working with the Hands' (1904); 'Tuskegee and its People' (1905).

TUSSAUD, tü-sō', **Marie Gresholtz** ("MADAME TUSSAUD"), founder of the well-known exhibition of wax-work in London: b. Bern, Switzerland, 1760; d. London, 16 April 1850. She learned the art of modeling in wax in Paris, where she assisted her uncle Curtius in his 'Cabinet de Cire' in the Palais Royal. For a time she gave lessons in modeling to Elizabeth, sister of Louis XVI, and in this way became acquainted with the leading personages at court. During the Revolution she was imprisoned for three months. In 1802 she established herself in London. The collection of over 300 portrait figures (that of Voltaire and others yet on view modeled by Madame Tussaud herself from life) with a remarkable collection of relics, is still one of the interesting features of London, where it is now managed by a company. Consult Hervé, F., 'Memoirs of Madame Tussaud' (London 1878).

TUSSER, tŭs'ẽr, **Thomas**, English agricultural writer and poet: b. Rivenhall, near Witham, Essex, about 1524; d. London, 3 May 1580. He was a chorister at Saint Paul's and elsewhere, studied at Cambridge, was for 10 years retainer and musician to Lord Paget at court, and farmed unsuccessfully in Suffolk and Norfolk. Later he was a singer in Norwich Cathedral, a tax-farmer in Essex, and a servant of Trinity Hall, Cambridge. Tusser of whom Fuller, in enumerating his vocations, says he was "more skilful in all than thriving in any," introduced barley-culture into England, and wrote the famous work 'A Hundredth Good Pointes of Husbandrie' (1557), later (1573) expanded into 'Five Hundredth Pointes of Good Husbandrie,' a series of practical directions on agriculture, written in rude dactylic verse, in which Sir Walter Scott finds he has "frequently attained . . . a sort of homely, pointed and quaint expression." Many proverbs have been derived from it. There have been many reprints and editions, including that for the English Dialect Society by Payne and Herrtage (London 1878). The rimes do not lack sound agricultural value, and Tusser has been styled the "British Varro." Consult Fuller, 'Worthies' (1662); Warton, 'History of English Poetry' (ed. Price 1840).

TUSSER, TUSSORE, or **TUSSEH,** the silk spun by the tusser silkworm. See SILKWORM.

TUSSILAGO, genus of plants of the general order *Compositæ*. The only species is the colts foot (*Tussilago farfara*), which is characterized by solitary flower heads appearing before the leaves. These are much sought after by bees and are, therefore, of economic value as honey producers apart from the general feeding value of the grass.

TUSSOCK-MOTH, one of the small grayish or brownish moths of the genus *Halesidota*, or some allied genus, whose cocoons are composed of silk and caterpillar hairs mingled, and are fastened in the interstices of the bark of trees. These moths defoliate trees, and feed upon a wide variety of hard woods. They are, consequently, a constant pest of parks and shade-trees, and measures must be taken to destroy the cocoons in winter, by scraping them off the trees or applying strong insecticides. A European species is a special pest of hop-vines. There are 20 species in the United States. The most destructive are the gypsy moth and the browntail moth which have wrought havoc in New England within the last 50 years. Consult Holland, W. J., 'The Moth Book' (new ed., New York 1905).

TUTELO, too-tā'lō. Strictly the name of a tribe of the former Monacan confederacy of the Siouan stock of North American Indians, who, when first known to the whites, in 1671, lived on the headwaters of the Dan in southwestern Virginia. The name, however, being a contraction of the Iroquoian designation (Todirich-roone) of all the Siouan tribes of the South Atlantic Coast was employed by the Iroquois in a more comprehensive sense. By 1675 the Tutelo tribe had drifted to the Roanoke River in southern Virginia, and by 1701 had occupied several parts of upper North Carolina, owing to pressure of the Iroquois from the north. Soon after 1711, with the remnants of the various tribes of Virginia and the adjacent parts of North Carolina, they were gathered at Fort Christanna, in the present Brunswick County, Va., where they became generally known as Christanna or Saponi Indians, although the latter name was strictly applicable to a single though cognate tribe. At Fort Christanna the tribes were thrown in contact with unprincipled whites, whose influence had the usual effect of rapidly degrading the Indians, although Governor Spotswood made an attempt to educate their children. The Iroquois raids continued, notwithstanding the proximity of the garrison, but these practically came to an end with the Albany treaty of 1722. Dissatisfied with their white neighbors, and particularly with the hanging of one of their chiefs, the Tutelo, Saponi and other confederated tribes resolved to follow the example of the Tuscaroras (q.v.) by placing themselves under the protection of the Iroquois. Consequently, about 1740, they began a gradual migration northward, settling first at Shamokin village, Pennsylvania, where Sunbury now stands. By 1748 they had settled at Skogari, in the present Columbia County, Pa., where they were described by Zeisberger as "a degenerate remnant of thieves and drunkards." In 1753 the Tutelo and their allies were adopted by the Cayugas, becoming a part of the Six

Nations. As the Iroquois espoused the cause of the British in the American Revolution, half of them, including most of the Cayugas, were driven into Canada, where they were settled on the Grand River reserve. The Tutelo went with them, erecting their village on "Tutelo Heights," a suburb of Brantford. About 1830 they still numbered some 200, but a smallpox epidemic in 1832 greatly reduced, and another in 1848 almost exterminated, the tribe. In 1871 the last full-blood survivors passed away. See Hale in 'Proceedings of the American Philosophical Society' (Vol. XXI, Philadelphia 1883–84); Hodge, 'Handbook of the American Indians' (Washington 1910); Mooney, 'Siouan Tribes of the East' (Washington 1894).

TUTICORIN, too-tē-kŏr'ĭn, India, a seaport in the province of Madras, situated on the northwest shore of the Gulf of Manar, 70 miles northeast of Cape Comorin. It is the terminus of the South Indian Railroad, has pearl fisheries and considerable trade. There are several cotton manufacturing establishments. Pop. 34,758.

TUTOR, *in Scotch law,* the guardian of a boy or girl while a minor. A father is tutor to his children by common law. Failing him, there may be three kinds of tutors — tutors nominate, tutor-at-law or tutor-dative, the division being borrowed from the Roman law. A tutor-nominate can only be appointed by the father, either under his will or by some writing clearly indicative of his wish. He is not generally bound to find security for his intromission with the estate of his pupil, but the Court of Session may ordain him to do so. A tutor-at-law is appointed by the court when there is no tutor-nominate, or when he dies, or does not accept. The nearest relation by the father is usually appointed if 25 years old and able to give security. But the tutor-at-law has only the custody of the pupil's estate, his person being entrusted to his mother, or, failing her, to his nearest relative on her side. A tutor-dative is named by the Crown when there is no tutor-nominate, nor at-law. The office is in all cases an unpaid one, and the tutor is bound to make inventories and to keep accounts. For certain important acts — selling land, for example — he requires the sanction of the Court of Session. Tutor is also applied to a Fellow of a college or university who discharges particular functions, the latter differing in various universities.

TUTTIETT, tŭt'ĭ-ĕt, **Mary G.** ("MAXWELL GRAY"), English novelist: b. Newport, Isle of Wight. Her first work was 'The Broken Tryst' (1879); but 'The Silence of Dean Maitland' (1886) at once brought her before the English and American public as one of the most notable of the later novelists, and is the book by which she will be longest remembered. Later works include 'The Reproach of Annesley' (1889); 'In the Heart of the Storm' (1891); 'Sweethearts and Friends' (1897); 'The House of Hidden Treasure' (1898); 'Ribstone Pippins' (1898); 'The Forest Chapel' (1899); 'The World's Mercy' (1900); 'Four Leaved Clover' (1901); 'The Great Refusal' (1906); 'Unconfessed' (1911); 'The Desire of the Moth' (1912); 'Something Afar' (1913); 'The Worldmender' (1916), etc.

TUTTLE, tŭt'l, **Daniel Sylvester,** American Protestant Episcopal bishop: b. Windham, Greene County, N. Y., 26 Jan. 1837. He was graduated from Columbia in 1857 and from the General Theological Seminary in 1862; was admitted to deacon's orders in 1862 and to the priesthood the next year. He was rector of Zion Church, Morris, N. Y., 1863–67, and in the year last named was consecrated missionary bishop of Montana, Utah and Idaho. He was translated to the diocese of Missouri in 1886, and in September 1903 succeeded Rt. Rev. Thomas March Clark as presiding bishop of the Protestant Episcopal Church. He is the author of 'Reminiscences of a Missionary Bishop' (1906).

TUTTLE, Herbert, American historian: b. Bennington, Vt., 29 Nov. 1846; d. Ithaca, N. Y., 21 June 1894. He was graduated at the University of Vermont in 1869, and soon after entered the field of journalism. His first newspaper work was in connection with the Boston *Daily Advertiser.* In 1872 he went abroad and for some years resided in Germany, where he became a correspondent of the London *Daily News,* the Glasgow *Herald,* and the New York *Tribune.* Here he devoted much time also to the study of German political history and international law, and upon his return to America was appointed resident lecturer in the department of political science at the University of Michigan, and in 1882 became professor of international law and the theory of politics at Cornell University. In 1890 he was appointed to the chair of modern European history at Cornell. He published 'German Political Leaders' (1876); 'History of Prussia to the Accession of Frederick the Great' (1884); and 'History of Prussia under Frederick the Great' (1888).

TUTUILA (too-twē'lä) ISLANDS, a group of the Samoan Islands (q.v.).

TUTUTUNNE ("people close to the water"). The name (1) of a gens or village on the north bank of Rogue River, above its mouth, in Oregon, and extended to include (2) a number of gentes or villages of the Athapascan stock of North American Indians in the same general locality. Little is known of the primitive customs of the tribe, but they formerly practised polygamy, and widows were buried alive in the graves of their deceased husbands. After hostility toward the government they were removed in 1856 to the Siletz reservation, where they have since resided. At the date mentioned they were officially reported to number 1,311, but they are now reduced to a few score.

TUY, twē, Philippines, pueblo, province of Batangas, Luzon, on Mantenlupâ River, 24 miles northwest of the pueblo of Batangas. It is surrounded by a cattle raising and agricultural region; and is connected with Balayan and the coast highway by road, and with the province of Cavité by a trail leading over the Sierra de Tagaytay. Pop. 2,430.

TVASHTRI, twăsh'trĭ, or **TVASHTAR,** in the Rigveda of the Hindus, the mythological creator, shaper or divine artisan, later classed among the Adityas or gods of heavenly light. He is the divinity who creates the gods, humankind, and animals, and rules their destinies. His daughter Saranyu, whom he married to Vivasant, was the mother of Yama and Yami, the primæval pair. The sun as the primary source of life and all blessings is supposed to

be the mythological origin of Tvashtri. Consult Barnett, L. D., 'Antiquities of India' (London 1913); and Macdonnell, A. A., 'Vedic Mythology' (Strassburg 1897).

TVER, tvār, Russia, (1) capital of the government of that name, on the Volga, 96 miles northwest of Moscow. It contains a Kremlin or fortress, surrounded by a wall, outside of the main town, has fine promenades, spacious open squares, handsome buildings, palace, churches, two monasteries, convent, Protestant and Catholic churches, etc. The cathedral of the Transfiguration is a remarkable structure with five cupolas, and fine mural paintings by Platon (18th century). Further a monument to Catharine II, theatre, various schools, seminaries and military academy. There are numerous manufactories, including cotton mills, iron-foundries, wagon works, saw mills, starch factories, etc. A brisk trade is carried on with Moscow and Petrograd. There are spacious docks and machine-shops. Pop. about 62,600. (2) The government contains an area of 25,225 square miles. The surface is mountainous, declining into a plain at the north. Forests are extensive and the fields yield rye, barley, hemp and flax. The Volga and the Dvina are the principal rivers. Cottage industries are extensive and produce linen, felts, shoes, axes, nails, crude implements, etc. There are also manufactories of cotton goods, leather, flour, etc. Pop. 2,250,200.

TWACHTMAN, twät'mąn, **John Henry,** American painter: b. Cincinnati, 4 Aug. 1853; d. Greenwich, Conn., 8 Aug. 1902. He came under the influence of Frank Duveneck in 1875, just as the latter was fresh from the studio of Pilotry at Munich, and was making a great impression in New York by his brilliant and rapid execution. Twachtman, at his suggestion, studied from 1875 to 1878 at Munich under Loefftz and subsequently at Paris. He eventually settled at Greenwich, Conn., developing an original line of artistic production, in which he tempered the crudeness of impressionism by a certain refined and tender sensibility, and manifested a fine sense of color in its most delicate shades and subtile combinations. He has been called a "minor poet of the brush." Without being a rich colorist, or a bold innovator he produced pictures fresh, original and finding their way to the heart by their pathetic simplicity, the truthfulness of their detail and the absence of all flourish and self-consciousness in the apparent ease and directness of their technique. His typical theme was a winter landscape, a stream of water rushing down a ravine, between thin edges of ice, and bare bushes on each side; a white house with dull colored roof, under a turbid gray sky; or the coolness, moisture and silence of a snow scene, whose atmosphere he suggested with truly marvelous felicity. If he was not fully appreciated in his lifetime his paintings will doubtless grow in popular estimation, and win recognition as vital incidents in the history of American art, gaining emphasis also from their personal interest as reflecting the artist's fine nature, his love of beauty in landscape, and his keen observation of the more fleeting and elusive phases of atmospheric change, the more sombre charms of rugged or barren scenery and clouded sky, in the seaboard of the Eastern States. An exhibition of his paintings was held in New York in 1913 and there was a Twachtman room at the Panama-Pacific Exposition, San Francisco, in 1915. His works are scattered throughout America, but he is well represented in all important galleries.

TWAT, twät, or **TUAT,** Sahara, a large group of oases situated to the south of western Algeria in lat. 27° to 29° N., and separated from the Atlas Mountains by the desert of El Erg. It contains several salt lakes, wadies and some artificial irrigation canals, and produces dates, wheat, senna, cotton, etc. The principal caravan routes from Timbuktu to Algeria and eastern Morocco converge at this point, and the trade is very important. The principal single oases are Guarara in the north and Twat proper in the south, the latter having several mosques and a population of about 49,000. The Algerian railway system reached Twat in 1912. It is in the French sphere of influence.

TWEED, twēd, **William Marcy,** American politician: b. New York, 3 April 1823; d. there, 12 April 1878. He was by trade a chairmaker and first gained political foothold through his popularity as foreman of the "Americus" Fire-Engine Company No. 6, known as "Big Six." He was an alderman in New York in 1852–53, United States congressman in 1853–55, chairman of the New York board of supervisors in 1856, school commissioner in 1856–57, deputy street commissioner in 1861–70 and State senator in 1867–71. From his appointment as deputy street commissioner the power of the famous Tammany Ring really dates. He was practically at the head of the department and with his support of unscrupulous political friends his power increased until when elected commissioner of public works in 1870 the "Tweed Ring" controlled practically every department of municipal expenditure. He increased enormously the city pay-roll, giving to political allies high-salaried sinecure positions. His largest scheme for robbing the city treasury was that of the county courthouse, begun in 1868 and planned to cost $250,000, but upon which $8,000,000 was reported as expended in 1871, leaving the building uncompleted. The charter of 1870 which placed the power of auditing accounts with certain city offices occupied by Tweed and his friends removed all restraints from the system of plundering devised by the unscrupulous politician and the amounts appropriated extended into the millions. A secret account of these depredations was kept in the auditor's office and in the winter of 1870–71 the items were copied by a clerk in the office and were printed in the New York *Times* in July 1871, resulting in the downfall of the "ring" in the election of the following November. Tweed was brought to trial in 1873 on a charge of grand larceny and forgery and sentenced to 12 years' imprisonment and a heavy fine. His sentence was reversed in 1875, but he was unable to furnish bail pending certain civil suits brought against him and was committed to jail. He escaped to Spain in 1875 but was brought back to New York on a warship and again committed to the Ludlow Street jail, where he died. Consult Bryce, 'The American Commonwealth' (new ed., 2 vols., New York 1910); McGuire, J. K., 'The Democratic Party of the State of New

York' (ib. 1905); Myers, G., 'History of Tammany Hall' (ib. 1901).

TWEED, Scotland, a river rising in Peebleshire at Tweed's Well and the largest stream of the country. At Coldstream it forms the boundary between England and Scotland and enters the North Sea at Berwick, after a course of 97 miles. Its chief tributaries are Gala and Ettrick Waters, the Leader, Teviot, Till and Whitadder. The chief towns on its route are Peebles, Melrose, Kelso, Abbotsford, Coldstream, Dryburgh, Norham Castle, etc., many of them rich in historical and literary associations. The river is celebrated for its trout and salmon fisheries. It is navigable for barges for a short distance above Berwick. Consult Crockett, W. S., 'The Scott Country' (1892); Lauder, T. D., 'Scottish Rivers' (1874); Veitch, J., 'The River Tweed' (1884).

TWEEDLEDUM and **TWEEDLEDEE,** a phrase used only in making reference to a distinction between the two. The suggestion is, of course, that the only distinction between the two is in sound, in other words a distinction without a difference. The expression arose in the 18th century in the course of a dispute between the admirers of Bononcini and those of Handel, as to the respective merits of those musicians. The matter was thus satirized by John Byrom (1692–1763):

> "Some say, compared to Bononcini,
> That Mynheer Handel's but a ninny;
> Others aver that he to Handel
> Is scarcely fit to hold a candle.
> Strange all this difference should be
> 'Twixt tweedledum and tweedledee."

TWEEDS, a certain kind of cloth, so called from the fact that its manufacture originated and was long exclusively carried on in towns on the Tweed and its tributaries. It is distinguished by the softness and flexibility of its texture, qualities which result from the manner in which it is made, the yarns not being so finely spun nor the cloth so closely woven or so thoroughly felted as is the case with the fine English cloths. Tweeds are also well known by their peculiar and endlessly varied patterns and mixture of colors, produced by weaving with dyed yarns. The manufacture is of comparatively recent origin; but the great demand for the material has led not only to the rapid growth of the manufacture in its original locality, but also to its extension to various other parts of Scotland and also into England, as well as to the imitation of the material in France and other continental countries.

TWELFTH CENTURY. This is the century of the crusades. The first crusade was preached in 1095 and the Latin kingdom of Jerusalem came into existence (1099) just before it opened. Men continued to go from Europe in large numbers during the first quarter of the century to strengthen the little Christian kingdom. The second crusade (1147) gave a new impetus and the third crusade (1190) attracted large numbers of men from Germany, France and England. It might be thought that with Europe pouring out hundreds of thousands of her men, the youth and chivalry of the time, so many of whom were killed or crippled, though the whole population was less than that of most of the countries now, the period would be distinctly one of sluggish transition and that great accomplishment could not be expected. In spite of all this the century witnessed the great beginnings of that magnificent intellectual and artistic movement at the end of the Middle Ages which culminated in the 13th century, a period that itself sent out the next three crusades. The intensity of feeling aroused by the heartfelt efforts of Europe to rescue the Holy Land from the Moslem more than made up for the physical losses and this deep stirring of the human mind and will led to some of the greatest achievements that humanity has ever made. The effect of this stimulus was noted all during the later Middle Ages and the movement affected all classes and made itself manifest in the smaller as well as the larger towns. The architectural impulse was felt particularly in northern France and was so widely diffused that "each village and hamlet of Northern France possessed a church that was commonly of real value. No matter how insignificant it usually contained some object of art of striking beauty, an altar piece or a painting or a statue or stained glass or a tombstone or wood carving or a bell or wrought iron work that still bear the stamp of the genius time." All this has been emphasized for us by the destruction caused by the Great World War and the effort to catalogue the losses. Other countries were but little behind France in following the impetus. Spain has a series of great cathedrals, the foundations of which are traced to this time, though the country was in the midst of a determined effort to free itself from the incubus of the Moors. Many of England's great cathedrals were begun before the 12th century closed, while in Italy the earlier Renaissance, as it is sometimes called, affected architecture, art and literature. Gothic or pointed construction — so-called in deprecation in the later Renaissance because not originating in classic antiquity it seemed only worthy of the Goths, their barbarous ancestors, came into existence. It has for its basic principle that ornament should not be for its own sake but spring from construction work, and the first hints of it have been traced to Sicily. The pointed style fascinated the crusaders on their return and the fashion for it soon became diffused all over Europe.

The political history is that of the crusades. The second crusade was preached by Saint Bernard, after the fall of Odessa, a frontier stronghold of the little kingdom of Jerusalem, awakened the fear that the Holy Places might again fall into the hands of the infidels Bernard was bitterly disappointed in what seemed its failure, but it saved Jerusalem for the Christians for a generation. The Holy City was taken by Saladin, the well-known sultan of Egypt (1187), and this brought on the third crusade in which the three greatest sovereigns of Europe, Frederick Barbarossa, the emperor of Germany, Richard I of England, the Lion Heart, the title won by his heroism in this crusade, and Philip Augustus of France took the cross (1190). The emperor led his troops by land, but the German crusaders suffered as did their predecessors on crusade from friction with the peoples of eastern Europe and from disease in Asia Minor. In spite of obstacles they achieved success, but Frederick was drowned, his troops became dis-

heartened, the Turks inflicted severe losses and only 5,000 out of 100,000 ever returned to their homes. Richard and Philip Augustus convoyed their troops by ship and joined their forces at the siege of Acre. The siege was long and costly, but in spite of all Saladin's efforts to relieve the garrison the city had to capitulate. A rupture between Richard and the French king led to the return home of Philip Augustus and his troops. The English king remained to complete the task of winning back Jerusalem, but in vain. The tales of the personal combats between Richard and Saladin and their immediate followers belong to romance rather than history, but have some foundation. Saladin proved an opponent worthy of the chivalry of Europe. Richard concluded a favorable peace with the provisions that the Christians should have free access to the Holy Places and hold all the coast from Acre to Ascalon. Richard's return was hastened by rumors that his brother John was plotting against his kingdom. On his journey from the Holy Land homeward the English monarch fell into the hands of his political enemy the German Emperor Henry IV, the successor of Frederick, and was imprisoned *incommunicado*. Blondin, the favorite minstrel of the king, wandering in quest of him, sang to his harp beneath the walls of Richard's German prison and his voice was answered by the king. The imprisonment of the champion of Christendom against the Turks evoked bitter protests, but Henry absolutely refused release except on payment of an immense ransom. The story has often been cited as typical of the political bad faith of the time, but analogous events are not rare in history, even in our time. Richard was so beloved of his people that even the enormous imposition demanded did not seem too much, and with the consent of the clergy they stripped the very churches to make up the sum. The Lion Heart returned to England to be enthusiastically welcomed by his people, though his death within a few years put John (Lackland), a younger brother, one of the most despicable of English monarchs, on the throne (1199).

Bishop Stubb's estimate of the crusades in his lectures on "Mediæval and Modern History," delivered as professor at Oxford, has now come to be the accepted view. "They were the first great effort of mediæval life to go beyond the pursuit of selfish and isolated ambitions; . . . they failed in their direct object, but that is only what may be alleged against almost every great design which the Great Disposer of events has molded to help the world's progress; for the world has grown wise from the experience of failure rather than by the winning of high aims. . . . They brought out the love for all that is heroic in human nature, the love of freedom, the honor of prowess, sympathy with sorrow, perseverance to the last." Besides they touched men's hearts and minds so deeply that they stimulated them to their highest activity and as a result the crusading generations and those which immediately followed them succeeded in accomplishing more great things that the world will never willingly let die than any other. They were a great manifestation of the power of the spirit of man, and while they brought immense material losses to Europe and entailed almost innumerable evils, they brought immense good.

The political hero of the time is Arnold of Brescia, born about 1100 and executed 1155, who came into enduring fame about the middle of the century. The Italian cities were at this time just developing independent republican existence under consuls with a senate and an assembly of free citizens. Arnold, a disciple of Abelard, campaigned for and obtained the re-establishment of the Roman republic. The Pope was deposed, a senate of 56 members was formed, the ancient letters S.P.Q.R. reappeared in the public documents, and the republic became a fact. Every city of any importance throughout Italy, except in the kingdom of Naples, followed the example and took on a republican form of government. The emperor Frederick I, known as Barbarossa, looked jealously at this spread of the spirit of democracy and crossed the Alps to assert his rights in the peninsula. Italy welcomed him with naïve confidence that he would confirm the established order. The emperor proceeded to use all his power against the young municipal republics. He restored the Pope and Arnold of Brescia was executed. When Frederick returned to Italy in 1158, reaction against him throughout Italy was general and when he attempted to place imperial officials over the Italian towns, many of them revolted. Frederick laid siege to Milan, which held out for two years and then yielded only to famine. The Milanese were compelled to destroy their *carroccio* which carried their standard of independence and the town itself was totally destroyed, many of the neighboring cities which bore old grudges being permitted to wreak their vengeance upon it. Frightfulness, instead of crushing the spirit of the Italian cities, aroused their patriotism. The league of the Lombard cities was formed and Frederick had to lead his forces into Italy six times. On his fifth expedition he was defeated by the Lombards at Legnano (1176) and was compelled at the peace of Constance to renounce all his claims over the Italian cities. Between the Italian cities and his own turbulent nobles, Frederick was almost constantly at war during a long life which was to end ingloriously in the Third Crusade.

The league of the Italian cities to preserve their liberties was one of the first confederacies organized in the modern spirit. Formed as the result of the conflict with the German emperor, they were unfortunately the scene of bitter conflicts between two parties among the Italians themselves, the Guelphs and the Ghibbellines, these being the Italian forms of the German names, Welf and Waiblingen. The Welfs or Guelphs were the Papal and popular party opposed to the Ghibbellines, the imperial and aristocratic party. The Welfs were so called from Welf I of a powerful family in the time of Charlemagne. Waiblingen was the name of an estate not far from Wurtemburg belonging to the House of Hohenzollern, hence its use as a rallying cry of the emperor's party at the battle. The names Guelph and Ghibbelline are said to have been first used as war cries at the battle of Weinsburg in 1140 in which the Hohenstauffen emperor, Conrad III, conquered Welf VI. The names lost their significance in Germany to a great extent to become extremely important in Italy and there continued to designate bitterly antagonistic parties till the end of the 15th century. The first Lombard League

included all the cities from Venice to Piedmont. Henry the Lion, chief of the Welfs, had refused to follow the emperor, hence the adoption of the name of the opponents of the emperor in Italy. The success of the effort of the league against Frederick led to its formation in the following century once more and brought the Italians their first appreciation of what a united Italy might mean.

Bishop Stubbs declared that the greatest man of the century in his influence on his own and subsequent times was Bernard of Clairvaux (1090–1153). At the age of 23, after an education which had awakened in him a taste for literature and tapped a vein of poetry, Bernard, wearied of the trifles of life, with 30 young noblemen of Burgundy who shared his feelings, asked for admission to the monastery of Citeaux, where the rule of Saint Benedict was being re-established in all its old-time rigor. Bernard responded so well to the monastic discipline that only three years later, Stephen, the abbot of Citeaux, sent him at the head of a group of religious to found a new monastery in the Vale of Bitterness (Absinthe) in the diocese of Langres. Bernard renamed the place *Claire Vallée,* or Clairvaux, Bright Valley, and his own name has had this for epithet ever since. Bernard though so deeply intent on mortification that his health was threatened by it, and the régime at Clairvaux was so austere that it would seem forbidding, had a marvelous attraction for men and numbers flocked to him. Even his father and six brothers came to share the peace and happiness of his religious life at Clairvaux. The monastery became so crowded that over and over again bands of monks had to be sent out for new foundations.

Here Bernard wrote his great books which are still often consulted and have been reprinted in most of the modern languages in our generation. Here he delivered his homilies and from here the letters were written which influenced his times so deeply and reveal the man to us. The poetic tendency of his earlier years was now turned to sacred poetry and Bernard wrote some of the most beautiful of hymns. He became known as *Doctor Mellifluous.* He was famous in philosophy and theology as well, and it was he who answered Abelard so effectively and yet with so little of acerbity that that distinguished university man felt that nothing more could be said. Bernard and Abelard became reconciled and Abelard became a monk at Cluny and a teacher in the school of the monastery. When the crusade of the middle of the century was to be preached, Bernard was felt to be the man of all others to lead it, and his voice stirred multitudes to take up the cross, and wonders attested by all who heard him enhanced his influence. The failure of the crusade to accomplish all that he hoped embittered the close of Bernard's life. The selfish pettinesses of men face to face with a great good work made him realize how little he could really touch them.

Bernard's opponent in theological controversy, Abelard, is the other famous intellectual genius of the century. He is remembered for his scholarship and his educational influence, but mainly for the romance in his life. Like so many errant geniuses of France, Abelard was born (*circa,* 1079) in Brittany, just coming of age for his life work in our century. He was destined to a military career, but preferred to become a wandering scholar, hearing the lectures of many of the renowned teachers of the day. Shortly after the beginning of the century he was at Paris for some time and occupied a chair in the cathedral school, the forerunner of the university, where he taught dialectics with great success. He became the idol of Paris and, as he says himself, had the world at his feet. In the midst of this adulation came the romance which ruined his career. The popular professor was engaged by Canon Fulbert to give lessons to his niece, Héloïse. She was deeply intellectual and became a devoted admirer of her brilliant teacher. She was handsome and before long the teacher was forgotten in the lover. There was a secret wedding after the birth of their son, and Héloïse retired to the nunnery of Argenteuil and Abelard gave up his professional career. He was but in minor orders at the time and now he became a Benedictine monk in the abbey of Saint Denis. He had a rather stormy career after this, one phase of which is touched upon in the paragraphs with regard to Saint Bernard, but the end of his life was spent in peace at Cluny. He was buried at the Paraclete, the nunnery of which Héloïse was the abbess. Their remains are now said to be in the cemetery of Père la Chaise (Paris), where their tomb is a place of sentimental pilgrimage. The surprise is to find a romance with all the modern elements working itself out over seven centuries ago.

Héloïse was not yet 20 when she met Abelard, a man of nearly 40, at the summit of his career, and was won by his prestige and his intellectuality. Later in life she attracted the attention of Peter the Venerable of Cluny and of Saint Bernard for her intellectual qualities, and the rules which she gave to her nunnery, the Paraclete, became the basis of the constitutions of many monasteries for women. She had great administrative power and her letters are a revelation of a wonderful mother heart, combined with an intellect of high order and a literary quality usually supposed to have developed only much later in history than the 12th century. The fault of her youth was amply expiated and she came to be looked up to as a great good woman whose advice on important questions was worth having and who was turned to by many of her contemporaries because of their thorough appreciation of her excellent judgment and her unselfish character.

The century had its intellectual life, many of the products of which have survived, mainly in the monasteries. Citeaux, Clairvaux, Cluny, have already been mentioned and the abbey of Saint Victor founded by William of Champeaux, archdeacon of Notre Dame, deserves a place beside these. William after lecturing to crowds of students in Paris, relinquished his chair and retired to a small hermitage dedicated to Saint Victor near the city, where he was followed by a great many of his pupils, Abelard among them, and was persuaded to take up his lectures again. This was the origin of the famous abbey and school of Saint Victor. With the schools of Saint Genevieve and Notre Dame, it afterward formed the basis of the University of Paris. Among its most distinguished scholars were many known only by their Christian names and distinguished by the appellative "of Saint Victor." There was Hugh of Saint Victor, termed

the Saint Augustine of his time because of his work in philosophy and theology and the breadth of his scholarship, and Richard of Saint Victor, a Scotchman, called the "mystic doctor" because of the lofty spirituality of his writings; then Adam of Saint Victor, whether a Breton or a Briton is not known, who wrote hymns which are among the greatest of the time, and this is the supreme period of hymn writing in history. Archbishop Trench declared Adam of Saint Victor "the foremost among the sacred Latin poets of the Middle Ages." Other Saint Victorians were Peter Comestor (d. 1178), the historian, Peter Lombard (1100–1164), the famous *Magister Sententiarum*, whose book was the basis of scholasticism and the subject of so many commentaries; Thomas the abbot of Saint Andrews, to whom Saint Francis sent young Saint Antony of Padua for his theological studies, and many others. Few schools in history have had so many pupils of enduring distinction in a corresponding space of time. The abbey was the centre of the intellectual life of Europe at this time and the Mecca for many distinguished visitors, not a few of whom came to remain for some time. The English were particularly interested in it, and the second abbot, Achard of Saint Victor, was either an Englishman or was related very intimately to the Normans in England at that time.

The hero of the century in the eyes of all his contemporaries and for centuries later was Thomas à Becket, the martyr archbishop of Canterbury (1118–70). A legend makes his mother a princess from the East who met his father on the crusades. Kept in duress by her father until à Becket's return to England, she escaped surveillance and followed with only his name to guide her. She found her lover to become a Christian wife and the mother of Thomas à Becket, later the archbishop. He was a brilliant student at Merton College, Oxford, and at Paris, and at 22 entered the service of Theobald, archbishop of Canterbury. He became a favorite of Theobald who sent him to study civil and canon law at Bologne and Auxerre. When Henry II succeeded Stephen as king of England, he made Thomas à Becket his chancellor at the age of 36. The king and his chancellor were said to have "but one heart and one mind." When Archbishop Theobald died in 1161, Henry selected Thomas as his successor. Thomas would have refused the offer saying "I know your plans for the Church. You will assert claims which I, as archbishop, must needs oppose." Henry insisted. The inevitable division of opinion foreseen by Thomas occurred, owing to the king's ambition, and the archbishop refusing to yield had, like many another archbishop, to go into exile. Reconciliation took place and Thomas returned to England but the disagreement as to Church and state rights recurred and the king said impatiently, before his nobles in Normandy, "Who will rid me of this troublesome Churchman?" Four knights immediately left the royal presence, crossed the channel to Canterbury, and finding the archbishop in his cathedral at vespers, slew him before the altar. The popular outcry over this bloody deed was intense. The king shocked at the unlooked for effect of his hot words did public penance, and for the rest of the Middle Ages and until King Henry VIII brought about the separation from Rome, the shrine of Saint Thomas at Canterbury was one of the most famous and one of the most visited in Europe. Many thousands of pilgrims found their way there every year. Chaucer has made the Canterbury pilgrimages live for all the after time though the destruction of the shrine put an end to them four centuries ago.

The 12th century witnessed a climax of the development of the right of sanctuary or the right of asylum as it is also called, which meant so much for the beginning of the reign of law instead of violence. It consisted in the privilege enjoyed by all those who were persecuted and were in danger of violence, whether the persecution was just or unjust, of flying to a church where they were guaranteed immunity against capture or violence of any sort on the part of their pursuers. This privilege endured so long as they remained on sacred ground. In the meantime the ecclesiastical authorities under whose protection the fugitive had come used their influence to secure justice or at least to calm the passion of the pursuer. What was needed above all was time and this was secured by this means. This right had been exercised during preceding centuries to very good effect, but a number of incidents during the 12th century shows that it was coming to be recognized by all, even by rulers, and that as a consequence many acts of injustice, some of them irreparable, which would have occurred if the fugitive were without refuge, were prevented. This right of sanctuary was without discrimination as to the social condition of the refugees and this fact had much to do with making social barriers less decisive than they had been.

JAMES J. WALSH,
Author of 'The Thirteenth Greatest of Centuries.'

PRINCIPAL EVENTS OF THE TWELFTH CENTURY.

1105. Henry I becomes King of England. Abelard opens a school of rhetoric at Paris. Héloise becomes his pupil.
1106. Henry V is crowned Roman emperor of Germany.
1114. The marriage of Matilda, daughter of Henry I of England, to Henry V, Roman emperor.
1115. Saint Bernard founds Clairvaux Abbey.
1118. Rise of the Knights Templars. By submission to the king the commons of France gain protection from the nobles. Villanage abolished.
1122. Abelard founds the monastery of the Paraclete of which his wife, Héloise, becomes superior.
1127. The Southern Sung dynasty established in China and exists under nine emperors until 1280.
1130. Creation of the kingdom of Naples and Sicily.
1133. Count Roger of Normandy invades Sicily.
1135. Stephen becomes king of England.
1138. Civil war in England.
1139. Portugal becomes a kingdom.
1141. Papal interdict laid on France.
1142. Death of Abelard.
1146. Saint Bernard preaches the Second Crusade. Roger of Normandy and Sicily invades Greece.
1152. The divorce of Louis VII of France from Eleanor, gives Guienne, Poitou, etc., to Henry II of England, who marries her, and wars ensue. The Troubadours flourish. The Albigensian persecutions begin.
1153. Death of Saint Bernard of Clairvaux.
1154. The Plantagenets assume power in England.
1155. Execution at Rome of Arnold of Brescia.
1156. Roman law and the Catholic religion definitely established in Germany.
1161. Thomas à Becket becomes archbishop of Canterbury.
1162. Milan is destroyed by Barbarossa.
1164. Death of Héloise.
1169. Invasion of Ireland by Henry II of England.
1170. Archbishop à Becket of Canterbury assassinated.
1176. Barbarossa of Germany leads his fifth expedition into Italy and is defeated by the Lombards at Legnano. The Peace of Constance is concluded. The first Lombard League is inaugurated.

1180. Philip II reigns over France. Summons John of England as a vassal.
1187. Saladin captures Jerusalem. The Third Crusade is preached.
1189. Circuit of justice introduced in England. Death of Henry II. Richard I of England, Barbarossa, emperor of Germany, and Philip Augustus of France join the Third Crusade.
1190. Defeat and death by drowning of Barbarossa. Siege and capture of Acre by French and English Crusaders. Quarrel between Richard and Philip, and withdrawal of the French from the Crusade.
1191. Saladin repulses all attacks on Jerusalem. Concludes a peace with Richard, giving Christians free access to all the holy places of Jerusalem.
1192. Capture and imprisonment of Richard I—Coeur de Lion—by Henry IV of Germany.
1194. Release of Richard by ransom.
1195. Several thousands of Europeans sacrificed in the Crusades. Return of the survivors.
1199. Richard I of England dies.

TWELFTH-DAY, Epiphany (the 6th of January), which is the 12th day from Christmas. This was formerly (as it still is) a day of great festivity and the evening of the day was the occasion of observing many curious customs. One of the most widespread of these was the baking of a cake (in England called twelfth-cake) with a bean in it, and dividing the cake among the partakers of the feast. Whoever got the piece with the bean in it was regarded as king for the remainder of the day, in France for the whole of the year. This custom is supposed to have been derived from that which prevailed among the Roman children at the end of the Saturnalia, of drawing lots with beans to see who should be king. In Italy it is customary to give presents to children on this day.

TWELFTH NIGHT. Just before Shakespeare began his series of great tragedies he wrote 'Twelfth Night' (1600–01) — the last of his great comedies. The play is notable for its blending of romantic beauty and charm in the story of the Duke, Olivia, Viola and Sebastian with a comic underplot in which are involved Maria, Sir Toby, Belch, Sir Andrew Aguecheek, Fabian and Malvolio. For the romantic story the author was indebted to several Italian stories which had been translated into French by Belleforest, and later into English by Barnaby Riche in his 'Apolonius and Silla.' The comic scenes and characters are the invention of Shakespeare, although they repeat many of the devices and effects of previous comedies. In fact the comic part of the play is a recapitulation of characters and incidents that had been successful in other comedies. Sir Toby and Sir Andrew belong to the family of Falstaff and Slender, while the clown is another Touchstone with a certain added maturity. The scenes in which the over-serious and self-centred Malvolio is made ridiculous by the clever devices of Maria are among the triumphs of Shakespeare's comic genius. Whether the interpretation of Malvolio's Puritanism as given in this play may be considered as Shakespeare's judgment is still a matter of debate. The conclusion of the comedy, in which the conflicting forces of love caused by the mistaken identity of Viola and Sebastian are resolved and the complete discomfiture of Malvolio is realized perfectly represents the subtitle of the play — 'What You Will.' The play was thus a sort of farewell to a type of dramatic writing in which Shakespeare had already achieved great triumphs. No comedy is more delightful or more fascinating. EDWIN MIMS.

TWELVE PATRIARCHS, Testaments of the, a work not recognized as in any sense Scriptural or authoritative, but of interest from the standpoint of ecclesiastical history. It was written in the 2d century after Christ, and purported to relate utterances of the fathers of Israel, foretelling the coming of the Saviour and discoursing on the results that would flow from that event. The predictions are modeled on those of Jacob, Gen. xlix, when the patriach blessed his sons and prophesied the future of them and their descendants before giving up the ghost. See APOCALYPTIC LITERATURE.

TWELVE TABLES, Law of the, the first written code of Roman laws, enacted in statutory form, having been drafted by a commission of 10 elected for the purpose and approved by the popular assembly (451 and 450 B.C.). It appears to have been a compilation of the older laws, founded on custom and precedent, but it formulated personal and property rights in such clear language that the patrician magistrates were no longer able to misinterpret and misapply them with impunity, as in former times. It was regarded by the people much as Americans regard the national Constitution, and Roman schoolboys learned the Twelve Tables by heart, even as late as the age of Cicero. A great body of rules grew up around the Twelve Tables, and as these called for expert legal interpretation, the study and practice of law gradually developed into a distinct profession. There remain to-day only fragments of this celebrated code. Many attempts at reconstructing it have been made, the latest by Voigt in 1883. Modern critics, never happy unless they can upset a tradition or two, contend that the Twelve Tables are a private compilation probably of the 3d century B.C. Consult Lambert, Edouard, 'Le problem de l'origine des Douze Tables' (Lyons 1902), and Appleton, C., 'Le testament romain: la méthode du droit comparé l'authenticité des Douze Tables' (Paris 1903). See ROME; DECEMVIRS.

TWENTIETH CENTURY. The opening year of the latest century was marked somewhat dramatically by the close of the long reign over the British Empire of Victoria of England, queen and empress, who died 22 Jan. 1901; by the assassination and death 14 Sept. 1901 of William McKinley, President of the United States, and by the accession of Theodore Roosevelt, Vice-President, to the chief executive office. Throughout the civilized world there was promise of peace and a growth of the spirit of humanity and internationalism. War between civilized nations seemed almost a thing of the past. Many World's Fairs, Universal Expositions, held in the preceding half century had brought the nations together as never before. Trade between nations as a medium for cementing friendship seemed to portend an ever-better understanding among rival peoples. The educated classes were drifting into a sense of security as regards war. A peace conference was held in Switzerland in the nineties and though it had broken up in disagreement the fact of its assembling seemed a great step forward. At the end of the century (1898) young Tsar Nicholas of Russia invited the nations to send delegates to a peace conference at The Hague. Most of them accepted. The conference was held (1899) and established a permanent court

of arbitration. Early in our century over 125 arbitration treaties between nations were arranged and statesmen considered the negotiation of such treaties as their highest activity. The second Hague Conference (1907) held at the invitation of the United States occupied itself with the drawing up of rules for humane warfare,—many of which were violated in the Great War. It strengthened the faith in peace and there were confident prophecies of a time soon to come when reason would rule international relations as it did personal relations since the disappearance of the duel.

In spite of the growing feeling that war was soon to be a thing of the past, when the century opened England was at war with the Boers and the United States was at war in the Philippines. In 1904 the bloodiest war that men had engaged in up to that time occurred between Russia and Japan. Just 50 years before Japan had been invited into the circle of civilization. When the Portsmouth (N. H.) treaty of peace (1905), signed largely through the influence of President Roosevelt, left Japan the victor, the yellow race had become a factor in world politics. Despite threatening incidents for seven years there was peace, but then the wars came thick and fast. Italy warred with Turkey over Tripoli (1912), the Powers refusing to permit the bombardment of Constantinople and limiting the war zone to Africa. The same year the first Balkan War broke out and the civilized world rejoiced when it seemed as though the defeated Turks were at last to be driven back to Constantinople. The dilatory diplomacy of the great nations in its fear of disturbing the balance of power, permitting Turkish atrocities to continue, made the world ready to welcome the removal of the sultan from Europe. The little Balkan nations, Greece, Serbia, Bulgaria, Montenegro, seemed about to accomplish what the "Great Powers" had balked over. Having disposed of the Turks with unexpected readiness the Balkan nations quarreled among themselves over the spoils and the second Balkan War, Greece and Serbia and later Rumania ranged against Bulgaria, proved one of the bitterest in the history of humanity. The same year the Mexican troubles, not yet concluded, began, and in the summer of 1914 the Great War broke out. The peace treaty was signed 28 June 1919 at Versailles, but fighting continued in many parts of Europe, so that no century of human history had so many wars in so short a time with so many killed and wounded and the end of it is not yet in sight.

The underlying motive of these wars was invariably commercial expansion. The Boer War resulted from English efforts for trade advantages in South Africa. The Russian-Japanese followed Russia's extension of her sphere of influence into Manchuria to obtain an ice-free port on the Pacific, her position in Europe denying her such an outlet for her commerce. In 1860 Vladivostok became a Russian port, but as it is closed during the winter Russia turned south toward Korea and the Manchurian coast. The Siberian Railroad was to be carried across Manchuria and its extension was made possible by the Japanese-China War (1895). The international convention after the Boxer Rebellion promised to shut out further encroachment on China, but Russia continued to advance and Japan declared war. Italy's war with Turkey was for Tripoli, the only portion of northern Africa left for the exploitation of European countries. The first Balkan War was almost a holy war in its purpose to expel the Turk, but the underlying motives were territorial expansion and commercial opportunities. The second Balkan War revealed this very clearly and was waged with supreme selfish disregard for human rights by grasping governments. The Mexican troubles were largely fomented by trade interests and grasping politicians. The Great War was rooted entirely in commercial rivalries and the fear that the growing power of other nations might prevent commerce and manufactures from having a free outlet into distant countries. Colonial expansion, the root of so many international difficulties, was almost entirely a matter of securing an outlet for the products of industry and the surplus population of European countries. The industrial era of the 19th century reached a climax of influence in which it was felt that the disposal of the industrial products of its people was the most important thing for government to secure. Many of the industries for which political striving was so earnest were employing men for such wages and under such conditions of health as made decent living almost impossible for a great many of those employed. The Great War produced internal conditions in all countries in which labor was in a position to claim rights that for a time seriously disturbed all national conditions. The war began for industrial expansion and commercial advantage redounded almost entirely to the benefit of labor in all the countries. What labor as the paramount influence in the lives of nations may do for mankind must depend on the ability of its leaders. With 7,000,000 able-bodied men killed in the war and another 7,000,000 so seriously crippled that they cannot do manual labor, at least 12,000,000 laborers were lacking from the world's labor supply. They were mainly the best labor elements, the able-bodied of military age. Their absence will surely affect the labor situation for some years to come. Everywhere then, as the second decade closes, there is unrest among the laboring classes and a striving for better wages. The outlook for better conditions for labor is promising unless political disturbances and a lack of community spirit are permitted to interfere.

Besides these wars a series of incidents all commercial in origin, carrying threats of war with them, occurred. In 1905 Germany's jealousy of the commercial rights which France had acquired in Morocco and which pointed to French absorption of that country seriously disturbed the world. The conference of Algeciras (1906) proved a diplomatic defeat for Germany, practically all the nations, including the United States, taking part against her. Germany's hopes were revealed. The German acquisition and fortification of Kiau-chau complicated the Far Eastern question; the proposed Berlin to Bagdad Railway with its strategic possibilities put another factor into the already complex Near East situation, while the rapidly increasing German navy threatened the development of superiority by sea as well as by land. This led to a lining up of the other

countries of Europe for self-defense. Germany's entrance into the Far East brought about (1902) an alliance between Japan and Great Britain, the first between a Western and an Eastern power. Mainly through the influence of King Edward VII (reigned 1901–10) England and France, hereditary enemies, composed long-standing difficulties (1904) and the hostility between England and Russia, due to their rivalry in Asia was replaced by an Anglo-Russian Entente. Persia, which had been a bone of contention between them, was divided into spheres of influence and a neutral section. Afghanistan, which had been a critical issue, was placed entirely under British influence and Tibet was to be respected. Great Britain, France and Russia thus made the Triple Entente as opposed to the Triple Alliance of Germany, Austria and Italy. This reconciliation of ancient enmities which brought about co-operation between these countries was due more to the influence of King Edward VII of England than any other single factor. After a rather stormy youth and a middle age given over to trivialities it seemed as though the long life of his mother, Queen Victoria, was fortunate in delaying his ascent of the throne and yet the 10 years of King Edward's reign accomplished much to align the world favorably for the great struggle that was to take place a few years after his death. He proved a diplomatic ruler of high order whose international influence was all for the best. The rapprochement between France and England probably saved Europe from war at the time of the Agadir incident when Germany sent a naval vessel to enforce her demands as to some compensation in Africa for the rights which France was securing in Morocco. The crisis was only delayed a few years.

The spirit of the time seething in so many wars had a beneficial effect in the political arena which will make the century forever famous in the history of democracy. Popular government and responsibility to the elected representatives of the people advanced as never before. The Liberals of England succeeded in modifying parliamentary law so that the veto power of the House of Lords on legislation was eliminated and as a consequence important measures of reform in taxation and franchise were passed. In Portugal King Carlos and the Crown Prince were assassinated 1 Feb. 1908 and Manuel II, younger son succeeded to the throne but in October 1910, fled before a revolution which set up a republic. The republic maintained itself though the monarchists have not ceased reactionary efforts. To the surprise of all, the Sultan of Turkey in July 1908 after a revolt in the army which threatened to prove serious proclaimed a constitution and elections were held and a new Parliament was opened in December. The Young Turks, representative of the better educated Ottomans' came to be the dominant party and liberalization was promised but the results were far from satisfying; cruelties continued and Turkey's entrance into the war against the Allies marked the doom of Turkish power in Europe. Austria took advantage of the disturbance in Turkey to annex Bosnia and Herzegovina placed under Austrian control by the Great Powers after the Russian-Turkish War. In October 1908 Prince Ferdinand of Bulgaria declared his country independent of Turkey and assumed the title of Tsar.

The most astonishing democratic development was the establishment of a republic in China where late in December 1911 a provisional republican government with Dr. Sun Yat Sen as President was proclaimed. This was all the more surprising because scarcely 10 years before the Boxer Rebellion (1900) had seemed to stamp China as hopelessly reactionary. The "Boxers," a secret society banded together for the extermination of the "Foreign Devils," laid siege to the foreign legations in Peking. A combined relief expedition from Japan, France, Germany, Russia, Great Britain and the United States occupied the Chinese capital, exacted a huge indemnity but signed an agreement for the maintenance of Chinese integrity. The dowager empress continued all powerful, for a decade, and then came the republic. In spite of certain reactionary movements, the President, Yuan Shih-Kai, "consenting" to be emperor for a time, the Chinese republic has maintained itself and in August 1917 entered the Great War on the side of the Allies.

In Russia the liberalizing tendencies of the young Tsar, so promising at the beginning of the century, gradually changed and utter autocracy prevailed. The Russian-Japanese War provided an opportunity for the liberal elements to press political reforms. With the army in the Far East the government had to yield but not until after the awful massacre of Bloody Sunday, January 1905, and harsh attempts at suppression which were rudely interrupted by the loss of the battle of Mukden (23 March 1905) and the annihilation of the Russian fleet in the East (27 May 1905). In August 1905 the imperial decree establishing a representative body, the Duma, though with very limited powers was issued. Unrest continued and a universal strike led to the granting of legislative powers. This body was arbitrarily dissolved the following year and another more complacent elected. This filled out its term as did the third Duma though without accomplishing much; but the fourth Duma was at hand in 1916 to demand the abdication of the Tsar when Russian affairs reached a crisis. The proclamation of a republic in 1917 seemed too good to be true and there are so many warring elements that the Russian people have still their political salvation to work out.

The greatest event of the century, the greatest of its kind in the history of humanity is the World War which lasted over four years and three months. On 28 June 1914, Archduke Francis Ferdinand, heir to the Austrian throne, with his wife, was shot to death in Serajevo, the capital of Bosnia. A bomb hurled by a printer aged 20 missed them, injuring others, but shots fired by a student, Princip, aged 19, proved fatal. Official investigation showed that the two assassins belonged to a Serbian secret society for revolutionary propaganda in Bosnia. Many Serbian high officials, hoping to unite the Serbs everywhere for action, were members of this. The annexation of Bosnia by Austria had aroused deep enmity in Serbia. Austria felt that this fomenting of revolution could no longer be per-

mitted. For the next three weeks Austrian diplomacy kept its own counsel, except so far as it was shared by Germany, but the authorities planned war against Serbia. In 1913 they had proposed aggregation against Serbia but Germany and Italy, as members of the Triple Alliance, refused to join it. The Austrian military purpose was so thoroughly hidden that many important diplomats and government officials of Great Britain, Russia and France, unsuspecting, went on their vacations in late July. July 23d, Austria's ultimatum to Serbia was delivered. War evidently was intended. No independent state could maintain its self-respect and accept the provisions. Behind Serbia stood Russia, unwilling to permit further Austrian encroachments in the Balkans. Germany was the ally of Austria and France of Russia and Great Britain had an understanding with both so that war would involve most of Europe. Serbia, taking counsel with foreign embassies, gave a most diplomatic reply, but could not submit completely. The Austrian Minister to Serbia withdrew at the end of the two days allowed for the reply and Austria declared war on Serbia 28 July. With Austrian mobilization, Russia mobilized and on this score Germany's Ambassador was instructed to withdraw from Saint Petersburg after having handed over a declaration of war 1 August. August 3d the German Ambassador to France declared a state of war because of aggressions at the frontiers. Germany seemed assured that England would not enter the war. The British Empire had but a few hundred thousand soldiers, the Boer War had been unpopular and had revealed British weakness and the threatened insurrection in Ulster, for which German munition plants supplied the arms, seemed to give assurance that England would refuse to enter a Continental war. Her great fleet made her mistress of the seas but it was felt that before this could count materially the war on the Continent would be over. When on 4 August it became known that German troops had invaded Belgian territory, Great Britain declared war. The German Chancellor in the Reichstag confessed that the invasion of Luxemburg and Belgium was "against the rules of international law" but the necessity of the situation demanded it. He promised "to atone as soon as our military end is attained." When the English Ambassador declared that the invasion of Belgium would mean war the German Chancellor suggested that "a scrap of paper" ought not to count for so much. Germany must be held responsible for the war at the bar of history, for though Austria precipitated it a word from Germany would have prevented it and not only was that word withheld but the publication of Austrian diplomatic documents (1919) shows that from early in July Germany urged such measures against Serbia as could only mean war. The most important witness against Germany is her own Ambassador in London during the crisis, Prince Lichnowsky, who published (1918) his account of the negotiations to prevent the war in which he found the English eager and anxious to avoid a conflict which they foresaw so clearly would prove ruinous for all concerned.

The first great phase of the war was the invasion of France by Germany with the idea that taken unawares the French would be put out of the war before slowly mobilizing Russia could be dangerous, and then the German armies might be turned to the Eastern front against the Russians. The advance of German troops through Belgium proved not only a political mistake, costing the sympathy of the world, but also a strategic error. The German armies were delayed in Belgium, affording time for French mobilization, though Belgium fortresses, supposed impregnable, rapidly crumbled before modern long-range high-explosive projectiles. The Germans approached Paris until the Eiffel Tower was in sight, when Von Kluck, commanding the German right wing, wheeled to the left (east) to cut off the French from their communications and precipitate a second Sedan on a far greater scale. On his exposed right wing a fresh army from Paris threw itself impetuously and the French centre under Foch holding, despite fierce attacks of Prussians and Saxons who were forced back, Von Kluck had to retire with immense losses and serious impairment of German morale. The plan of a short decisive war was at an end. The Germans entrenched and the long-drawn-out trench warfare of the next four years began. As Ivan Bloch had declared 15 years before, the spade proved more important than the rifle. This first battle of the Marne, fought along the historic river where for centuries Teutons and Franks had met, is one of the decisive conflicts of history. The ultimate conflict of the war was to be a second battle of the Marne, which also went against the Germans. After the first Marne battle the German objective became the Channel ports instead of Paris, and the bitter conflict of the fall and winter was in the mud of Flanders along the Yser around Ypres. The English and Belgians, supported by the French under Foch, heroically held against the massed attacks of the Germans though at awful cost in men. The "contemptible little" English army multiplied itself by valor. The Belgians, sturdily brave in misfortune, opened the sluices as their countrymen had so often done before against enemies, and the Germans were kept from the Channel ports.

On the Eastern front corresponding ultimate failure of objective met the Central Powers. The Germans defeated the Russians signally at Tannenberg, taking many prisoners. In August 1914 the Austrians planned an offensive, invaded Russia, but were driven back into their own territory, tried to reorganize there and lost another great battle, which gave the Russians possession of Lemberg, capital of Austrian Galicia. The Russians next invested the strongly fortified city of Przemysl, while the rest of their troops pushed on to the outskirts of Cracow, capital of Austrian Poland. Przemysl fell (March 1915) and the Russians from the heights of the Carpathians looked down on Hungary, which seemed at their mercy. The Germans had to rush men from their Western front to save the situation, and this afforded time for British army organization. Serbia was overrun and suffered intensely for the rest of the war. The Russians made a masterly retreat, came back under Brusiloff late in 1916, while the Germans were attempting Verdun and the Austrians were engaged with the Italians in the Trentino and

seemed in sight of victory. Austria had to hurry picked troops from the Italian front and the Germans had to summon forces even from Verdun to meet the overwhelming attack which carried the Russians to the very gates of Lemberg once more and gave them nearly 500,000 prisoners. Encouraged by Russian success Rumania entered the war on the side of the Allies 27 Aug. 1916. For a while her armies made progress against the Austrians, and there was hope of Russian co-operation, but the progress of disintegration had already begun in Russia and the supplies of food and oil to be obtained in Rumania tempted the Central Powers to a great drive which completely overwhelmed the Rumanians. The armies of the Central Powers entered Bucharest under Falkenhayn and Mackenson 6 Dec. 1916, and for the remainder of the war Rumania had to suffer as an occupied country.

In the spring of 1915 an attempt was made to take Constantinople. English troops, strengthened by forces from Australia and New Zealand, who had come by way of the Red Sea, landed at Gallipoli. The expedition was badly managed and in spite of the most heroic bravery made no progress. An attempt to aid the land troops by the British navy was answered by such well-directed fire that important naval vessels were sunk. A later British invasion of Mesopotamia seemed at first destined to like failure. Kut-el-Amara was captured by the British, but they were surrounded and had to surrender after intense suffering. Better organization led to the recapture of Kut, and Bagdad fell (March 1917) and Jerusalem was taken by the English troops (December 1917). One of the significant developments in connection with these expeditions was the self-sacrificing loyalty of the Dominion troops to Great Britain. The Australian-New Zealand auxiliaries (Anzacs) gave an example of bravery at Gallipoli that has never been surpassed. The Canadian troops stamped their names immortally on Flanders fields and proved second to none in the dauntless courage with which they attained objectives set them.

Having refused to take her part in the Triple Alliance with the Central Powers at the beginning of the war, Italy, unable to obtain the cession of *Italia Irredenta,* unredeemed Italy, that is territory occupied mainly by people of the Italian race still under Austrian rule, was forced by popular opinion to enter the war on the side of the Allies 23 May 1915. Gradually the Italian armies pushed their way into Austrian territory, greatly lessening Austria's power of resistance to Russian invasion, but making slow progress because of Alpine heights as the fighting terrain. The advance continued with some intermission all during 1916 and the greater part of 1917, when a surprise attack of German-Austrian troops brought the defeat of Caporetto (24 October), due partly to a new mode of attack, but mainly to a defeatist propaganda among the Italian troops. All northern Italy was laid open to the invader and over 250,000 prisoners were taken. The coming of British and French troops steadied the Italians and there was an immense patriotic reaction which strengthened the morale of the Italian troops. After this Italy proved a valuable factor in the war, claiming the attention of Austrian troops and proving a resource for Greece and the Balkan nations.

The year 1917 was the high tide of war effort and success for the Central Powers, and they felt on the strength of their position at the end of it that the war was surely won. Germany held most of Belgium and northern France, and the most determined and costly attacks had failed to dislodge her. Serbia overrun was held by the Central Powers and most of Rumania was in their possession. From Berlin to Bagdad German influence was supreme. The collapse of Russia enabled them to put their agents in control of large portions of it as the Brest-Litovsk Treaty revealed. The defeat of Italy back to the Piave in the autumn nearly put that country out of the war. There was doubt for a time as to whether Italy could come back effectually, but she did. The hopes of the Allies were at their lowest ebb just as America entered the war and the U-boat sinking of nearly 1,000,000 tons of shipping a month, unknown then, but now revealed, seemed to portend an enforced unfavorable peace. The situation grew worse in prospect rather than better during the spring of 1918, for German drives made disturbing progress. The appointment of General Foch as commander-in-chief of the Allied armies and the increase of Americans on the line in France gave renewed hope to the Allies. After Foch's counter-attack, beginning 18 July, the Central Powers crumbled, no other word can describe the unexpectedness of their collapse, and the armistice was signed 11 November.

The importance of naval power was demonstrated completely. The English fleet maintained its supremacy and protected England's commerce, so indispensable for the country. A single month's interruption of commercial intercourse would have put England in severe straits; two months would, it is said, have compelled capitulation. Germany's commerce was completely interrupted, though when submarine freighters came to the United States our genuine neutrality was shown by readiness to furnish supplies. This form of commercial relations proved too difficult and Germany's segregation from the world by sea more than any other single factor brought about German collapse and the end of the war. A great naval engagement was looked for between the rival fleets, but did not come. A portion of the German fleet met a strong detachment of the British (31 May 1916) but the engagement was hampered by mists and interrupted by darkness. The English lost about twice as many vessels and men as the Germans but their claim that the Germans escaped complete defeat only by retreat in the darkness was confirmed by the absence of any further attempt on the part of the German fleet to risk an engagement. After the armistice was signed the immense German fleet steamed across the North Sea and surrendered at Scapa Flow, where a few months later it was sunk by its officers in violation of their parole.

In spite of England's command of the surface of the seas the submarine warfare came very near proving the vital turning point of the war. Only the revelations made by Admiral Sims make it clear how serious were England's affairs from this danger when America entered the war. If the German U-boat campaign had

continued for even a few months to be as disastrous as it had been, British authorities felt that the end of the war could not be far off. American naval aid proved as important a factor for ultimate victory as military assistance on the Continent in the following year. American enterprise and ingenuity solved the problems of U-boat resistance and robbed this German naval arm, the real cause for the forcing of America into the conflict, of its power. Some 2,000,000 American troops were convoyed to Europe with a loss of scarcely a hundred, and communications which ensured the victualing and supply of our armies in Europe and of the English people were maintained in such a way as to prevent any serious interference with work or war.

Early in 1917 the Germans had finished enough submarines to make them confident of being able to put an end to English commerce. They declared a barred zone around the British Isles (1 Feb. 1917), offering a permit for one United States ship a week to reach Britain. Submarine warfare had already strained the relations with the United States; the sinking of the *Lusitania* (7 May 1915), with 1,200 men, women and children, over 100 American citizens, had created bitter feelings; other sinkings of American vessels were explained diplomatically, but the bitter feelings grew. When unrestricted submarine warfare was declared diplomatic relations were broken off and Count Von Bernstorff, whose connection with disturbing machinations in this country made him unpopular, was sent home. Sinkings continued, hostile relations with Mexico against the United States were attempted by Germany, and on 6 April Congress approved the President's declaration that the United States had been forced into the war. The United States was totally unprepared, but the first troops, regulars, reached France in July. It was not, however, until the beginning of 1918 that American troops in large numbers were sent to France. In the meantime peace negotiations had been suggested by Germany, and 8 Jan. 1918 President Wilson issued a program of world peace with 14 points, to be prominent on peace negotiations. The Quadruple Alliance: Germany, Austria-Hungary, Bulgaria and Turkey negotiated a peace with the Bolsheviki in control of the Russian government. This Brest-Litovsk peace, so called from the town in Poland where representatives met, showed that the Germans were intent on dismembering Russia for the benefit of the Central Powers. March 21, 1918 the Germans began a great "peace drive" on the Western front to force the Allies to sue for peace. The British were driven back almost to Amiens, but with the French held firmly. April 9 the Germans attempted to break through the British between Arras and Ypres to reach Calais and the English Channel. The British command to die at their posts, "backs to the wall," checked this. The third great German thrust came on 27 May and was answered by a counter-attack by the Americans, who took Cantigny. A week later the second and third American divisions stopped the Germans at Chateau Thierry. The German armies prepared for the fourth great drive, 15 July, and for three days seemed to be breaking through, but were held, and on 18 July Foch began the counter offensive. This was a complete surprise and proved the beginning of the end. Colonel Sargent in 'The Strategy of the Western Front' tells the reason: "But it was perhaps not so much the surprise due to the concealment of his forces prior to attack that deserves mention, as it was the surprise caused by the rapidity of the blows which he struck and the unexpected places where they fell. Hardly had the Germans been driven from the Chateau Thierry salient when Rawlinson attacked from the British front toward Chaulnes and Debeney from the Montdidier front toward Lassigny and Roye. These attacks were soon followed by Mangin's attack toward Noyon and Byng's toward Bapaume. Then came Horne's great attack from Arras toward Cambria and Douai, followed shortly afterward by Pershing's double attack against the Saint Mihiel salient." The American capture of the Argonne Forest was one of the great events of history. Many an army in preceding generations had tried to take the Argonne Forest by direct attack when the ground was not so thoroughly fortified as at this time, but no army ever succeeded in taking it until the Americans overran it at the end of September. This broke the spirit of the German armies, for it was recognized that there were millions more Americans to come over and that resistance was hopeless. As a matter of fact, all the preparations had been made to have 5,000,000 of Americans in France during the following year. The British forces in France are in striking numerical contrast. Mrs. Humphrey Ward published (1919) the official chart of the British general staff. The actual fighting strength January 1916 was 470,000. The maximum was reached (April 1917) 760,000. The number continued to descend and in May 1918 was 540,000 with but 465,000 on armistice day. At that time America's total forces in France were nearly 2,000,000 and 1,390,000 (General March's figures) were on the firing line. The French figures were not available but the opinion of military authorities is that they had less than 1,000,000 of men in actual combat on armistice day. The Americans had more than three times as many as the British and perhaps one and one-half times as many as the French. Nothing shows so clearly the factor that America was in ending the war as these figures.

The Peace Treaty saw the application of the principle of self-determination of the nations which made very important changes in the map of Europe. Finland became independent. Poland, which had disappeared as a country a century before, divided by Prussia, Austria and Russia, was now restored to its former status, the seaport of Dantzig on the Baltic being given to it. A new state, Czecho-Slovakia, consisting of the former provinces of the Austrian Empire, Bohemia and Moravia, was established. Hungary became independent of Austria; it was thus limited to a very small territory around Vienna. The Eastern Slavs formed Jugo-Slavia, consisting of Serbia, Croatia and Slavonia with Bosnia and Dalmatia. Race characters were made the foundation of boundaries in the Balkans. Greece acquired territory in Macedonia. Rumania had its territorial boundaries rearranged to include people of similar race. Bulgaria was restricted in its frontiers, and the Ottoman Empire in Europe disappeared.

At the beginning of this century the Irish problem, so thorny for several generations, seemed to approach solution. Land bills passed by Parliament had given the tenantry rights and the Congested District Boards solved housing problems. One of the first important applications of the elimination of the veto power of the House of Lords was made for a Home Rule bill, which passing the Commons three times and rejected by the Lords was signed by the king, thus becoming a law (September 1914). Because of the war it was suspended. For some time Ulster, the northern part of Ireland, though represented in Parliament by a majority of Home Rule members, had been threatening at least in and around the city of Belfast, to revolt if Home Rule were granted. They bought arms from Germany and openly drilled recruits. When the order was given to mobilize against them a number of the most important officers in the army refused to serve. In spite of this situation Redmond, leader of the Home Rulers, announced that the Nationalists would support the war. The continued suspension of the Home Rule Law caused grave discontent and in April 1916 an insurrection broke out in Dublin led by the Sinn Fein (Gaelic for "We ourselves," pronounced shin fāne), and proclaimed an Irish Republic with its own flag. The rebellion was suppressed, the leaders captured and ruthlessly put to death, though clemency to the Boers under similar circumstances had proved the value of a conciliation policy. The Irish people were rendered thoroughly disaffected and peace in Ireland has since been maintained by coercion. Though self-determination has come for practically all the other peoples of Europe, as the result of the war, it has not come for the Irish in spite of their age-long struggle for it.

A very prominent feature of the history of the century centres around votes for women. Certain of our Western States and New Zealand and Australia granted the suffrage to women in the later 19th century and with the establishment of The Commonwealth of Australia full Parliamentary suffrage was granted to women (1901). Finland (1906), Norway (1907), Sweden (1912), Denmark (1915) enacted woman suffrage. In England the suffrage leaders, tired of Parliamentary methods for securing the vote for women, resorted to violence. From 1905 to 1910 this policy was continued and, as has been the case with regard to manhood suffrage in the first half of the 19th century, proved more effective so that in 1910 a woman suffrage bill passed a second reading of the House of Commons but was then shelved. Violence continued but without legislative result though the question was being forced upon many minds. With the outbreak of the war the militant suffragists announced suspension of agitation so that the women might devote themselves to the country's needs. They rendered such service to the country in many ways that opposition to woman suffrage largely diminished. The Reform Bill of 1918 granted the ballot to women over 30 years of age with certain real estate conditions. This gives the franchise to some 6,000,000 of women. In the United States the Western States, which granted votes to women, had been well satisfied with the legislation and the suffrage movement was spreading even before the war. With the magnificent devotion to national purposes exhibited by the women of the country during the war other States granted the vote and opposition to woman suffrage in America notably lessened. Congress passed a bill authorizing an amendment to the Constitution granting the vote to women. This has to be approved by the legislatures of three-fourths of the States, but there is almost assured prospect of such approval.

Education suffered severely from the war. Attendance at European universities in the countries at war fell to a small percentage of what it had been before for all healthy young men were at the front. For a time it seemed as though university professors would have little to do but the war called many of them to do special work connected with their department for war purposes. The application of science so as to make war more destructive than ever sadly diminished the prestige of intellectual attainments. Soon another derogatory element exerted its influence. Most of the professors in German universities signed a document directed to the educated classes of the world, proclaiming that the war was not of Germany's making but was made by her enemies for her humiliation in jealousy of her magnificent progress during the past generation. Germany was waging defensive war for the Fatherland. A manifesto signed by 3,500 German teachers, professors and lecturers proclaimed the belief that the salvation of the culture of Europe depended upon the victory which Germany was about to achieve. The word culture became equivocal. German education was thrust from the pedestal which it had occupied in the academic world and lost the prestige which it had acquired, particularly here in America, during the preceding generation.

This revelation of the inner meaning of what was thought highest in modern education was due to the fact that German universities and schools were state institutions and faculties felt compelled to support government. The value of academic freedom was realized as never before, though it was pathetic to see that great mental attainments proved insufficient to give that independence of judgment which might be expected of men looked up to as leaders of the intellectual life of Europe. The tendency to set success in life as the principal goal of education was unveiled. The incidents led to a review of the reasons for German prominence in education and its definite elimination. At the end of the war Germany had lost not only her position in world affairs but above all her primacy in the academic world.

An even severer blow to the prestige of university teaching was the discovery that academic chairs had been made pulpits for the spread of the doctrines which animated the Central Powers during the war and which proved a shock to the rest of the world. The struggle for life had been taken in a very literal non-Darwinian sense as the order of the universe in securing the survival of the fittest. This was particularly applied to international affairs and charity and justice were supposed to be things apart from national aggrandisement. The three great apostles of these teachings, which had not been taken quite seriously out-

side of Germany but deeply influenced German academic minds, were Nietzsche, Treitschke and Bernhardi. Nietzsche, with some mental disturbance from early adult life, spent many years before his death in an insane asylum. In a series of books he supplied pan-Germanism with a basic philosophy. A typical expression was, "Ye say it is the good cause which halloweth even war, I say unto you 'it is the good war which halloweth every cause.' War and courage have done more great things than charity." Instead of the Christian law of charity Nietzsche proclaimed "this new commandment which I give you, Oh my brethren, Be ye hard." Treitschke was a professor of history at the University of Berlin attracting large audiences by the spell of his eloquence. The basic principle of his philosophy of history was that a state is not subject to the moral law. Its only policy is expediency and even its treaties bind only so long as it is advantageous to keep them. "A state cannot bind its will for the future as against another state. A state has no superior judge over itself and it will conclude all its treaties with this tacit reservation." Bernhardi, much read in Germany, was scarcely known in other countries, for his teaching seemed too contradictory of accepted principles to be taken seriously. It was the culmination of the philosophy of Nietzsche and the philosophy of history of Treitschke as applied to the 20th century situation. Bernhardi hailed war as the greatest good. Nature wanted the survival of the fittest and war brought that about. "Might is at once the supreme right and the dispute as to what is right is decided by the arbitrament of war. War gives a biologically just decision since its decisions rest on the very nature of things." The materialistic philosophy of the later 19th century had run itself out to its legitimate conclusions and a great educated people proceeded to apply those conclusions and the world then had to take them seriously.

The literary output of the century was mainly notable for its lack of serious significance. There was never so much reading in the history of humanity and books sold as never before and never so much attendance at plays and never so much money made by novelists and dramatists, but there is more than a serious doubt as to the enduring literary value of anything written in the century. The war stimulated some young poets "whose souls were touched by flame in the trenches" to flights of song higher than for a generation, but even with the stimulus of war nothing has been written that is taken seriously as great poetry and great literature. Reading has become very largely a recreation, attendance at the theatre to a great extent a dissipation of mind and serious thoughts are not welcomed. Large collections of books are available for all those who wish to make use of them but three out of four of the volumes taken from the libraries are of fiction, just as about the same proportion of the theatres are filled with audiences intent on light musical comedy. Great museums are visited by discouragingly few people, one in 10 or less of the population goes once a year, and popular education seems to have resulted largely in the cult of the trivial.

The 20th century was a period of enterprising invention and adventurous discovery. After years of effort the North Pole was reached by Peary 6 April 1909, and only two years later the South Pole was reached by Amundsen 16 Dec. 1911. He preceded Scott with a British expedition by but a few weeks. Wireless telegraphy became a means of communication even to the antipodes, invaluable for ships at sea, saving many lives; wireless telephony became an actuality. The triumph in invention was the solution of the problem of flying by the Wright Brothers in America. The Great War brought intensive development of aviation so that just after the war (1919) transoceanic flight was not a surprise. Facility of communication progressed, annihilating distance. Men developed ever so much greater power to use physical resources. There was some question whether the mental side of humanity was not pushed into the background by this. Rodin, the French sculptor, said that the telephone represented man's ear, stretched out to hear a thousand miles; the fast express train was a lengthening of his legs to get over ground as if with "seven league boots"; as man's mind remained the same, exaggeration of the body without corresponding mental development made a monster of him. During the Great War the applications of science added immensely to destruction and to the toll of human lives and suffering demanded by the struggle. Man's material progress proved as potent for ill as for good.

The world figure of the first two decades of this century is Theodore Roosevelt, born of an old Dutch family with a Celtic strain of which he was proud. He won back seriously threatened health by years of ranching in the West to be robust and vigorous, and developed into a man of broad views who in every position looked to the general good rather than that of any faction despite what might be the result for his own career. The Spanish-American War brought him into national prominence; elected governor of New York and then Vice-President for McKinley's second term, the assassin's bullet made him President at a moment when the "big interests" were in control of our politics. He set himself to oppose them for the benefit of the people, and while the advocates of special privilege roused opposition to him he became the most popular individual in the United States. Under his leadership the Progressives became a great factor in politics. His activity in bringing about the peace conference between Russia and Japan and the value of his influence in securing the acceptance of peace conditions made him a world figure. He put aside a third successive term as President though he might have argued that his first incomplete term did not bring him under the traditional restriction and there seems no doubt that he could have been President again. When the reactionary movement gained the upper hand he brought the defeat of President Taft and came to be looked upon as the most striking personality in the country whose opinions were considered as always thoroughly representative of the best interests of the whole people. At the beginning of the war he offered to organize and lead a division on the Western front. His four sons were prominent in the war. He died suddenly 6 Jan. 1919, re-

gretted by all his fellow-countrymen even by those who had not followed his leadership.

JAMES J. WALSH,
Author of 'The Thirteenth Greatest of Centuries.'

PRINCIPAL EVENTS OF THE TWENTIETH CENTURY.

1901. 22 January Queen Victoria of the British Empire dies. Edward VII proclaimed king and emperor. President McKinley shot 6 September, died 14 September. Theodore Roosevelt, Vice-President, becomes chief executive of the United States. Pan-American Exposition at Buffalo. Pan-American Congress in the city of Mexico. Hague court of international arbitration instituted. Australia extends the suffrage to women.
1902. Anglo-Japanese alliance to preserve the integrity of China and Korea. The first congress of the republic of Cuba assembles in Havana. Peace treaty signed between the Boers and the British. The California Pious fund controversy with Mexico arbitrated by The Hague tribunal. The Samoan dispute decided in favor of Germany by King Oscar of Sweden. Reciprocity treaty established between Newfoundland and the United States.
1903. Panama Canal Treaty rejected by Colombia. State of Panama secedes, proclaims a republic and concludes Isthmian Canal Treaty with the United States. Assassination of the king and queen of Serbia. Death of Pope Leo XIII; election of Pope Pius X. Alaskan boundary dispute decided in favor of the United States. Russia disregards Japan's representations over encroachments in Manchuria.
1904. Russo-Japanese War. Anglo-French treaty settles Newfoundland, African and other disputes. British expedition into Tibet reaches Lhasa. Louisiana Purchase Exposition at Saint Louis.
1905. Defeat of the Russian army and navy. Treaty of Portsmouth, N. H., ends Russo-Japanese War. Anglo-Japanese treaty of alliance renewed. Parcels post treaty effected between the United States and Great Britain. Norway separates from Sweden. Wright brothers invent the aeroplane.
1906. Pan-American conference at Rio Janeiro. Earthquake and fire destroys two-thirds of San Francisco. Franco-German embroglio over Morocco settled by the Algeciras conference. First Douma or Parliament opened in Russia in May, dissolved in July. Parliament opened in Persia. End of Dreyfus case in France. Separation of church and state in France. Norway independent elects Haakon VII king. China restricts the opium traffic. War between Central American republics.
1907. Second Russian Douma or Parliament lasts from March to June. In Finland, under full woman suffrage laws, 19 women are elected to the Diet. New Parliament opens in the Transvaal. Hostile demonstrations against British rule in India. In China, reform movement overthrows old educational and military systems. Universal suffrage in Austria strengthens the Socialist party. Women suffragists in England make violent demonstrations. The second Hague conference meets. Japanese laborers excluded by law from the United States except by passport. Interstate Commerce Commission in the United States prosecutes corporations for violation of the anti-trust laws. Tercentennial celebration of the settlement of Jamestown, Va.
1908. United States Congress remits $13,000,000 of Chinese Boxer indemnity. United States and Japan agree on Pacific Ocean affairs. United States severs diplomatic relations with Venezuela. King and crown prince of Portugal assassinated. Belgium annexes Kongo. Bulgaria declares independence. Sultan of Turkey restores the Constitution. The powers unite to prevent war.
1909. Austria annexes Bosnia and Herzegovina. Peary reaches the North Pole. Hudson-Fulton celebration at New York.
1910. King Edward VII of England dies; George V succeeds. South Africa union is proclaimed. Arizona and New Mexico admitted to statehood. Pan-American conference meets at Buenos Aires. Aerial navigation makes great progress.
1911. Revolution in Mexico. President Diaz resigns and sails for Europe. Francisco I. Madero elected President. Chinese National Assembly is dissolved. The republic of Portugal is recognized by the leading powers. War between Italy and Turkey in Tripoli. George V, king of England, crowned emperor of India at Delhi. Amundsen reaches the South Pole 16 December.
1912. China, the oldest of monarchies, becomes a republic 12 February. Italy annexes Tripoli 23 February but war continues with Turkey until 18 October and the signing of the Treaty of Ouchy. The Balkan League declares war on Turkey, 30 September and the first Balkan War begins.
1913. Parcel post system established in the United States. War of the Balkan allies against Turkey ended by the Treaty of London 30 May. The second Balkan War, between the Balkan Allies, begins 29 June, and is ended 10 August by the Treaty of Bucharest. President of Salvador assassinated. Ex-President Madero of Mexico assassinated. Woman suffrage introduced in Hungary. The first Parliament of China assembles. The Gettysburg semi-centennial celebration. Dedication of the palace of peace at The Hague.
1914. Direct wireless communication established between Germany and the United States. Treaties of arbitration ratified by the United States Senate with Great Britain, Norway, Sweden, Switzerland, Portugal, Spain, Italy and Japan. Formal opening of the Kiel Canal. Assassination of Archduke Francis Perdinand of Austria and his wife. Declaration of war by Austria against Serbia. The World War begins.
1915–1916. The World War.
1917. 2 April. The United States declares war against the illegal acts of the German government and joins the Entente Allies to end the conflict.
1918. Germany sues for peace and hostilities cease 11 November. See WAR, EUROPEAN, and related operations.
1919. Theodore Roosevelt dies suddenly 6 January. Franco-American-Anglo treaty of alliance defends France from unprovoked attack by Germany. Peace treaty, signed at Versailles 28 June 1919, reconstructs Europe and provides for a league of nations against war. Trans-Atlantic flights made by aeroplanes and dirigible balloons.

TWENTY THOUSAND LEAGUES UNDER THE SEA. This popular romance by Jules Verne tells an exciting story that makes a powerful appeal to the imagination of most young people and to not a few of their elders. The author launches immediately into his story, gives himself over to it, has confidence in it and trusts to events rather than to style to attain his purpose. As a result, no critic has ever spoken well of his style, yet all concede his ability to tell a rarely good story. 'Twenty Thousand Leagues under the Sea,' though written in 1869–70, before the invention of the submarine, remains to-day the most fascinating story of its kind, surpassed only by the truth, which has again shown itself stranger than fiction. Many details of Verne's sea-monster fit startlingly the modern submarine, and the present-day reader finds in the romance, if much to entertain, little to astonish him. The story is carried on by a well-balanced group of characters, not the least of whom is Conseil, the faithful servant, who captivates the boy reader as does Friday in 'Robinson Crusoe.' Apart from its series of thrilling adventures which render this romance of the sea so good a story, the book is most remarkable as an anticipation of events which actually surpass it in all the elements of romance. In this respect it is, and will remain, an example of the sheer prophetic power of the creative imagination.

RAYMOND WEEKS.

TWICE TOLD TALES, The, was the earliest published work of Nathaniel Hawthorne with the exception of a juvenile romance, 'Fanshawe.' After his graduation from Bowdoin College in 1825 Hawthorne lived a secluded life at his mother's modest home in Salem, and wrote and rewrote many tales. No publisher would accept a collection of these, but S. C. Goodrich brought out a number of them in his annual, *The Token*, and a few of them appeared in other places. It was not until 1837, when a college friend secretly gave the publisher a guarantee against loss, that these were collected and issued in book form. The title chosen calls attention to the fact that they had been printed before. An enlarged edition of the 'Twice Told Tales' appeared in 1842. The volume of 1837 was the first work of Hawthorne to bear his name, and it did some-

thing toward introducing him to the public; but it was not until the success of his romances directed attention to these earlier works that their value was fully perceived; and the author could still refer to himself as "the obscurest man of letters in America." The 'Twice Told Tales' occupy an important place in the development of the short story in America, and the best of them show all the distinctive qualities of Hawthorne's work. While he had no definite and preconceived theory of the short story, Hawthorne's feeling for form and proportion led him to produce stories that marked a great advance on those of his predecessors. It was in his reviews of the 'Twice Told Tales' that Poe first formulated his dicta regarding the short story which have since been accepted by almost every critic of that literary form. Among the characteristics of Hawthorne seen in the 'Tales' are his fondness for old New England settings, as in the four 'Tales of the Province House,' 'The Gray Champion' and many more; his interest in psychological studies, and especially in those which involve the effect of some sin or ambition on the soul, as in 'Wakefield,' 'The Minister's Black Veil,' 'Lady Eleanor's Mantle,' etc.; his habit of centring his tales about a material object, as in the 'May-Pole of Merry Mount,' 'Endicott and the Red Cross' and others already named; and his use of an elusive but powerful suggestiveness, which varies from a passing hint like the falling of the withered rose-leaves in 'The May-Pole of Merry Mount' to the carefully elaborated ending of 'The White Old Maid.' The volume also contains a few pieces like 'Sights from a Steeple' and 'Sunday at Home,' which are in no sense tales, but which illustrate the author's power of interesting the reader in a quiet account of slight and seemingly unimportant details. Even in the tales proper, the plots, judged according to standards developed by later writers, are not especially elaborate or ingenious. The portrayal of character is not always vivid, though the reader is rarely conscious of any notable deficiency in this respect. The author excels in the representation of ordinary human beings in situations that produce mental or moral stress, in the creation of an effective atmosphere or tone and in so weaving his incidents and foreshadowing their outcome as to produce a perfect impression of unity. Those who wish to make a careful study of one of the tales for the sake of Hawthorne's technique can do no better than to choose 'The Ambitious Guest.'

WILLIAM B. CAIRNS.

TWICHELL, Joseph Hopkins, American Congregational clergyman and author: b. Southington, Conn., 1838. He was graduated at Yale in 1859, and served as chaplain during most of the Civil War. In 1865 he accepted a call to the Asylum Hill Congregational Church, Hartford, Conn. His writings include 'John Winthrop' (1891) and 'Some Old Puritan Love Letters' (1893).

TWICKENHAM, twĭk'n-ăm, England, a town or urban district of Middlesex, on the Thames four miles southwest of London. In the 18th century it was a fashionable resort. It is now a residential suburb. Here are Walpole's villa and Orleans House, once the residence of Louis Philippe. Pop. 29,367. Consult Cobbett's 'Memorials of Twickenham' (London 1872).

TWIG-GIRDLER; TWIG-PRUNER. See GIRDLER.

TWIGGS, twĭgz, **David Emanuel,** American soldier: b. Richmond County, Ga., 1790; d. Augusta, Ga., 15 Sept. 1862. He was appointed a captain in the Eighth Infantry in March 1812, served in the War of 1812 and in 1814 was promoted major. He also fought in the Seminole and Black Hawk wars, and in 1836 reached the rank of colonel. During the Mexican War he rendered important services, and was brevetted brigadier-general for his conduct at Palo Alto and Resaca de la Palma, where he commanded Taylor's right wing. He commanded a division at Monterey, received the brevet of major-general, was for a little while governor of Monterey and then joined Scott at Vera Cruz. He commanded the Second division in the advance on the City of Mexico; at Cerro Gordo he led the attack, and at Contreras and Churubusco and at the city gates he performed efficient service. In 1861, while in command of the Department of Texas, he unresistingly surrendered to the Confederates the United States property entrusted to his care, and was in consequence dismissed from the army. Entering the service of the Confederacy, he held a brief command in Louisiana, but toward the end of 1861, on account of infirmities of age, he resigned.

TWIGGS, Levi, American marine officer, brother of David Emmanuel Twiggs: b. Richmond City, Ga., 1793; d. Chapultepec, Mexico, 13 Sept. 1847. He entered the marine corps as second lieutenant in 1813, and was senior officer of marines on the frigate *President* during her last cruise under Decatur. At the outbreak of the Mexican War he joined the expedition under General Scott and was killed in the assault upon Chapultepec.

TWILIGHT, daylight which continues after sunset, called crepuscular light. Twilight is occasioned by the reflection of sunlight from the higher parts of the atmosphere which are still illuminated after the sun has become invisible from ordinary heights. Light is reflected from the upper air till the sun is about 18 degrees below the horizon, but the duration of twilight is manifestly much influenced by the state of the atmosphere as to clouds, etc. In low latitudes, both on account of the quickness with which the sun traverses the 18 degrees below the horizon and because of the transparency of the atmosphere, there is little twilight. On the other hand, in latitudes higher than 43 degrees twilight at certain times of the year lasts from sunset to sunrise.

TWILIGHT SLEEP. This term is used as the equivalent of the German term Dämmerschlaf, a fanciful term applied by Krönig and Gauss for the method used by them in the delivery of parturient women at their private hospital for women in Freiburg, Germany. It was claimed by them in 1914 that they had been using it for 15 years with great success and they certainly have been fortunate in spreading abroad the knowledge of it and drawing patrons from many parts of the world. It consists in the hypodermatic use of a combination of scopolamine and morphine in solution

from the beginning of labor pains and continued at sufficient intervals to keep the patient semi-narcotized and in a state of amnesia so that she is oblivious of the fact that she is in labor or that she has labor pains, or even that she has a baby when it is born. The dosage is graded according to the tolerance of the patient and repeated as often as she appears to be coming out from its influence. Krönig and Gauss assert that it is uniformly or nearly uniformly satisfactory in depriving labor of its suffering, that it has few fatalities, that occasionally, rarely, an infant is apparently narcotized, but that suitable effort will always, or nearly always, relieve this. They insist that it is a great boon for women to proceed to labor with the assurance that the much dreaded pain of that ordeal will be eliminated, that the mental effect will prove very stimulating and offer to the woman a much more desirable prognosis than she could have by other methods of treatment at present in vogue.

An account of the method of treatment at the Freiburg institution was published by two laymen (women), who had been there and familiarized themselves with the method, in *McClure's Magazine* for June 1914. The treatment requires the constant attendance and watchful care of the physician from the moment the first hypodermic of the mixture is given. It is quite possible that it may result in morphine poisoning if given unadvisedly and there is a very real danger that the infant may be still-born. It seems a little strange if the method has all the merits which are claimed for it that it should have been used so long in Germany and not have found favor at the great maternities at Berlin, Munich, Vienna, Prague and elsewhere, but none of these great institutions seems to have been sufficiently impressed with its importance to take it up and use it as a matter of routine in its obstetric service.

After the appearance of the article above mentioned the method was tried in several hospitals in New York and Brooklyn and under skilful obstetric management. In the two years which have passed since then it has been used in some hundreds of cases with very good success, as reported in various contributions by those who have tried it and advocate it. But it has failed to meet general approval with obstetricians just as it seems to have failed to excite enthusiasm in Europe.

The combination of these drugs has been used in this country a number of years as a preliminary to general anæsthesia before the performance of a major surgical operation. Its effect in the experience of the writer in such use has been good; it calms the patient's fear, slows the pulse and keeps it slow during the operation, and relieves the patient of the post-operating tendency to vomiting. Also the patient may sleep uninterruptedly for many hours after the operation, which frequently is a great advantage.

It is not receiving the attention or discussion which it had a year ago, and it seems likely that the slight wave of popularity with which it was ushered in has passed along, like anæsthesia by injection of certain fluids into the spinal canal which a few years ago was used by numerous obstetricians but now has been practically abandoned because of its danger. For many years obstetricians have made use of ether and chloroform during labor and it would be hard to imagine anything more effective than one or the other of these in relieving the severe pain of parturition when it is properly given. Its effect passes off more quickly than the scopolamine-morphine combination and when chloroform is used it is rarely followed by vomiting or other unpleasantness. There is a mortality to ether and chloroform, and also a certain morbidity, but the percentage is so small it would be unwise to discard such beneficent helps. If it were possible for the use of scopolamine and morphine to be applied to 100,000 unselected cases and compared with an equal number of cases in which chloroform was used it is probable there would not be a very great difference in the mortality and morbidity of the two methods. It is quite improbable that there will be any revolution in obstetrics from the twilight sleep influence and from present appearances it will very soon be one of the curiosities in obstetric practice.

TWILL, a textile fabric, in which the weft threads do not pass over and under the warp-threads in regular succession, as in common plain weaving, but pass over one and under two, over one and under three, or over one and under 8 or 10, according to the kind of twill.

TWIN FALLS, Idaho, city and county-seat of Twin Falls County, on the Oregon Short Line Railway, 35 miles south of Shoshone. Abundant water power is provided by the Shoshone Falls. It has a general manufacturing business and makes candy, harness and vinegar. Pop. about 5,000.

TWIN-LEAF, an herb (*Jeffersonia diphylla*) of the barberry family, found in the northeastern United States. It has solitary four-parted white flowers, an inch across, borne on slender scapes, and succeeded by capsular fruits. The radical, long-petioled leaves are peculiar, the cordate blade being divided to the very base, forming two obliquely ovate lobes, entire, or again somewhat lobed, glaucous beneath and appearing to be twin leaflets. The leaves arise in tufts from a thick, horizontal rootstock, which is somewhat fleshy, and is said to be stimulative and antispasmodic. It has been employed as a remedy for chronic rheumatism.

TWISS, Sir Travers, English jurist: b. London, 19 March 1809; d. there, 15 Jan. 1897. He was graduated at Oxford, and afterward from 1842 to 1847 was professor of political economy there. In 1852–55 he occupied the chair of international law at King's College, London, and in 1855–70 was regius professor of civil law at Oxford. In 1862 he was made advocate-general of the British Admiralty, and in 1867 was knighted and appointed advocate-general to the queen. In 1872 he retired from public office, but was occupied with various state affairs, notably with the drafting of a constitution for the Kongo Free State, for the Belgian government, and in 1884–85 was counsel extraordinary to the British embassy at the Congress of Berlin. His published works include 'The Oregon Territory: Its History and Discovery' (1846); 'View of the Progress of Political Economy in Europe Since the Sixteenth Century' (1847); 'The Law of Nations' (1861–63); 'Monumenta Juridica: The Black

Book of the Admiralty' (1871–76) and 'Belligerent Rights on the High Seas' (1884).

TWO GENTLEMEN OF VERONA, The. 'The Two Gentlemen of Verona' would seem to be Shakespeare's earliest attempt at romantic comedy of the popular Italian sort. The play is mentioned in Meres's list in 1598, but was not printed before the folio of 1623, and appears to have been little acted either in Shakespeare's time or since. No evidence for a very early date exists except the logical improbability that this comedy could have been written by Shakespeare as late as 'A Midsummer Night's Dream,' 'The Merchant of Venice' and other works which show much higher mastery in the same line. As 'Love's Labor's Lost' is particularly a study in language and 'The Comedy of Errors' in plot construction, 'The Two Gentlemen of Verona' is primarily a study in characterization — crude as yet but interesting in its foreshadowing of what Shakespeare was later to do. We are reminded of 'A Midsummer Night's Dream' in the interlocking fates of the contrasted pairs of lovers; of 'The Merchant of Venice' in Julia's talk to Lucetta of her suitors and in the servant-clowns; of 'Twelfth Night' in Julia's disguise; of 'Romeo and Juliet,' finally, in Valentine's device of the rope-ladder, in the rendezvous of Silvia and Eglamour at Friar Patrick's cell, and in the passing mention of Friar Laurence (IV, ii, 37). 'The Two Gentlemen of Verona' is notably deficient in ability to portray real feeling. The plot proceeds by the help of conventional tricks and artificial dialogue. The representation of the awakening of love in Julia (I, ii) and in Silvia (II, i) is quite insincere, while the indifference with which Proteus's perfidy is treated and the essential weakness of Valentine chill the reader. There are, however, three elements of promise: the breath of deeper sympathy in the play's best scene (IV, ii), where Julia and the Host look on while Proteus woos Silvia; the fine song, one of Shakespeare's best, in this same scene "Who is Silvia, What is She?" and the melancholy Launce with his dog Crab. The story of Valentine was perhaps invented by the dramatist, but the part of the plot which concerns the fickle Proteus and the true-hearted Julia is apparently an adaptation of the tale of Felismena, one of the episodes in Montemayor's long pastoral novel, 'Diana Enamorada.' An English translation of this Spanish work was not printed till 1598, but several versions seem to have been current earlier in manuscript, and the outline of the tale was otherwise available.

TUCKER BROOKE.

TWO HARBORS, Minn., city, county-seat of Lake County, on the Duluth and Iron Range and the Lake Superior railroads, 28 miles northeast of Duluth. It is a large ore shipping point and also ships lumber and pulp wood. Pop. about 5,500.

TWO KETTLE INDIANS (mistranslation of Oóhenónpa, lit. "Two-boilings"), one of the seven divisions of the Tetons, who in turn form part of the great Dakota confederacy of the Siouan linguistic stock, the other divisions being the Brulés, Sans Arcs, Blackfeet or Sihasapa, Minniconjou, Oglala and Hunkpapa. The Tetons took possession of the Black Hills region of North Dakota, which had previously been occupied by the Crow Indians, long before white men came. They were noted for their prowess in war, and have had, with other Siouan tribes, numerous conflicts with the whites. The Tetons are on reservations, as follows: 4,907 Brulé, Lower Brulé, "Northern," Loafer, under Rosebud agency, South Dakota; 467 Lower Brulé under Lower Brulé agency, South Dakota; 2,471 Blackfoot Sioux, Minniconjou, Sans Arcs, and Two Kettles under Cheyenne River agency, South Dakota; 6,608 Oglala under Pine Ridge agency, South Dakota; about 500 Blackfoot Sioux and 500 Hunkpapa under Standing Rock agency, North Dakota. Total Tetons (est.), 18,098, not including Sitting Bull's refugees in Canada, about 100 in number.

TWO NOBLE KINSMEN, The, a pathetic drama founded on Chaucer's' 'Knighte's Tale,' and first printed in 1634, with the names of Shakespeare and Fletcher on the titlepage as authors. That Shakespeare wrote any part of it is not now believed, but Massinger and Rowley are sometimes suggested as collaborators with Fletcher.

TWO-PHASE SYSTEM. See ELECTRICAL TERMS.

TWO RIVERS, Wis., city in Manitowoc County, on the Chicago and Northwestern Railroad and on Lake Michigan, seven miles northeast of Manitowoc. Its manufactures are office furniture, dentists' and printers' cabinets, gasoline engines, aluminum novelties, woodenware and knit goods. Pop. about 6,000.

TWO SICILIES, Kingdom of the. See SICILIES, THE TWO.

TWO-THIRDS RULE, a provision of constitutional and parliamentary law intended to restrain and prevent unjust and inconsiderate action on the part of majorities. It was unknown in the legislative assemblies of ancient Greece and Rome, and has no precedent in the Parliamentary history of Great Britain. It may be regarded as American in its origin, and grew out of the jealous vigilance with which the smaller communities included in the Union of States sought to safeguard their political rights. The Constitution of the United States, in conferring on the Senate the power to try impeachments, provided that no conviction should be had by less than a two-thirds vote, thus securing to a minority of the States as represented in the Senate, the power to decide the result. The effect of the two-thirds provision, in the case of President Andrew Johnson, when tried on articles of impeachment, was to prevent his conviction, the vote being 35 senators for conviction and 19 for acquittal. A change of one vote would have carried conviction, and although public feeling ran high at the time, some senators who voted against the President expressed themselves in subsequent years as gratified with the result. In this case the two-thirds rule had exactly the effect intended by the framers of the Constitution. A similar rule regarding trials of impeachment has been adopted in State constitutions. The Constitution of the United States also provides that in the event of a veto by the President of any measure which has passed Congress, an affirmative vote of two-thirds shall be necessary to enact the measure into law, and such vote must be taken by yeas and nays, and the names of

the persons voting entered on the journal of each house respectively. This rule has also been adopted in the States in which governors possess the power of veto.

The two-thirds rule is best known through its adoption and political effect in national conventions of the Democratic party held for the nomination of candidates for President and Vice-President of the United States. It was adopted in the first Democratic National Convention, held in the city of Baltimore, 21 May 1832, when the Committee on Rules reported the following resolution:

«Resolved, that each State shall be entitled, in the nomination to be made of a candidate for the Vice-Presidency, to a number of votes equal to the number to which they will be entitled in the electoral colleges under the new apportionment in voting for President and Vice-President, and that two-thirds of the whole number of votes in the convention shall be necessary to constitute a choice.»

The rule applied only to the nomination for Vice-President for the reason that there was no difference of view as to the nomination for President, Andrew Jackson being the unanimous choice for the latter office, while there were several candidates for the Vice-Presidency. Martin Van Buren was nominated for Vice-President under the two-thirds rule, and was elected to preside over the very body which, by the casting-vote of John C. Calhoun, the former Vice-President, had rejected his nomination as Minister to England.

In the Democratic National Convention of 1836 no reference was made to the two-thirds rule. Martin Van Buren was nominated for President without opposition and Richard M. Johnson received more than a two-thirds vote on the first ballot for Vice-President. In 1840 Van Buren and Johnson were again made the candidates of their party, without any necessity for invoking the two-thirds rule. They were defeated in the election by Harrison and Tyler.

In the Democratic National Convention of 1844 the two-thirds rule was reaffirmed, and made to apply to both President and Vice-President. Van Buren had a majority of votes for the Presidential nomination, but less than two-thirds, and he maintained this majority on the first eight ballots. Opposition to him was strong, however, and on the ninth ballot James K. Polk, of Tennessee, who had not received a vote until the eighth ballot, received the entire vote of the convention. He had not even been a candidate for the nomination, and his name had not been put formally before the convention, when its members agreed, in view of the opposition to Van Buren, to make him their nominee. The supporters of Van Buren had apprehended from the first that the adoption of the two-thirds rule would involve his defeat, and they opposed it strenuously, the debate on the question lasting a day and a half. Since its adoption in 1844 it has never been disputed in Democratic National Conventions. The convention of 1848, which spent three days in organizing, followed the rule, and it was again reaffirmed in 1852 when Lewis Cass, the leading candidate, was defeated, and Franklin Pierce nominated on the 49th ballot. Cass had a majority on many ballots, but did not command the necessary two-thirds, while Pierce did not receive a vote until the 40th ballot. In the convention of 1856 James Buchanan had a majority for President early in the balloting, but did not receive the necessary two-thirds until 17 ballots had been taken.

The Democratic National Convention which met in Charleston, S. C., 23 April 1860, was the most exciting ever held in the history of the party, and the enforcement of the two-thirds rule in that body may be said to have indirectly brought about the Civil War. The convention was in session for 10 days, and took 57 ballots without making a nomination. Stephen A. Douglas had a majority over all on all ballots, but could not obtain the necessary two-thirds. There were 303 votes in the convention, and 202 were necessary to a choice. The convention adjourned to Baltimore, and there the party divided on the issues which brought about the conflict between North and South in the following year. It is generally agreed that Douglas, if nominated at Charleston, and supported by the whole strength of his party, would have been elected, and civil war avoided. That this would probably have been the result is indicated by the fact that Abraham Lincoln, the Republican candidate, received a popular vote of 1,866,152, against a popular Democratic vote of 1,375,157 for Douglas and 847,953 for Breckenridge, indicating a large popular majority, and electoral majority also, for the Democratic candidates, had the party been united. In subsequent Democratic conventions the two-thirds rule has been adhered to, but at various times its repeal has been earnestly urged by many Democratic party leaders and newspapers.

TWO-WIRE SYSTEM. See ELECTRICAL TERMS.

TWO YEARS BEFORE THE MAST, by Richard Henry Dana, Jr., is a truthful narrative that has all the fascination of fiction. When the author was advised to try a sea voyage for his health, which had become impaired during his student days at Harvard, he rejected the conventional pleasure trip to Europe, and shipped as a common sailor on a vessel bound from Boston around Cape Horn to what is now California and Oregon. Gold was not yet discovered, and the cargo chiefly sought was hides. On his return he published, in 1840, the account of his experiences which has become an American classic. It gives an admirably vivid account of life on a sailing vessel in the days when the old American merchant marine was at its best, and it shows glimpses of the Pacific Coast that are interesting in view of later historical developments. Young Dana was not only a close observer but a «good mixer.» His descriptions of ocean storms, of the wild scenery around the Cape, of the coast country, of the details of navigation and the stowing of cargo are supplemented by sympathetic and very real portrayals of his shipmates during the long cruise. Though he did not write for the sake of effecting reforms, his recital of unnecessary hardships and abuses to which the crew were subjected attracted public attention, and had a salutary effect. His style is not ambitious, but is apt, direct and admirably suited to his material. It may have been this lack of apparent effort that made publishers slow to accept the work. The manuscript is said to have brought the author but a

nominal sum, but the merits of the book were promptly recognized as soon as it was published, both in England and in America. While by no means a "juvenile" it is a narrative of unfailing interest for boys. A later edition, published in 1869, contains an added chapter which gives an account of a later trip to California; this is of both comparative and biographical interest. Handsomely illustrated editions of the work have been published in recent years.

WILLIAM B. CAIRNS.

TWOMBLY, Alexander Stevenson, American Congregational clergyman and author: b. Boston, 14 March 1832; d. Newton, Mass., 19 Nov. 1907. He was graduated at Yale in 1854 and at the Andover Theological Seminary in 1858. From 1859 to 1872 he held pastorates in Cherry Valley, N. Y., Albany, N. Y., and Stamford, Conn. He also served as chaplain in the Army of the Potomac. In 1896 he retired from the ministry and devoted himself to literary work. He wrote 'The Choir Boy of York Cathedral' (1890); 'Masterpieces of Michelangelo and Milton' (1896), and 'Hawaii and Its People' (1900). He also edited the silver series of 'English Classics.'

TYAN-SHAN, tē-ān'shān', **THIAN-SHAN,** or **CELESTIAL MOUNTAINS,** central Asia, a range of mountains running in an easterly direction from the Pamir plateau along the northern boundary of the Tarim Basin (East Turkestan) into southern Mongolia. In the east it forms a more or less connected ridge, but toward its western extremity it spreads out, fan-like, into a number of diverging ranges. The highest point, situated near the western end, is Tengri Khan, with an altitude of little over 24,000 feet. See HIMALAYA.

TYBEE, tī-bē', an island in Chatham County, Ga., at the mouth of the Savannah River. It is about six miles long and three miles wide. The waters surrounding it are on the north Tybee Roads, on the east the Atlantic, on the south Tybee Creek and on the west Lazaretto Creek. The Tybee lighthouse is on the northeastern end; it is 144 feet high; the white dioptric light is 150 feet above the water and is visible 18 nautical miles. The lighthouse is in lat. 32° 1′ 20″ N., long. 80° 50′ 31″ W. In the Civil War it was occupied by the United States forces, under command of Brigadier-General Sherman, 28 Nov. 1861 and batteries were subsequently erected on it and the adjacent islands, for the reduction of Fort Pulaski at the mouth of the Savannah River, commanded by Colonel Olmstead of the Confederate army. The bombardment began on the morning of 10 April 1862 from 11 batteries, between 1,500 and 3,000 yards from the fort, mounting 20 guns and 16 mortars, and the fort capitulated at 2 o'clock the next afternoon.

TYCHO BRAHE, tī'kō brā'ĕ. See BRAHE, TYCHO.

TYCOON, or **TAIKUN,** tī-koon', a Chinese word meaning "great prince." The title was formerly conferred by foreigners on the shogun or commander-in-chief of the Japanese army.

TYLER, Bennet, American clergyman: b. Middlebury, Conn., 10 July 1783; d. South Windsor, Conn., 14 May 1858. He was graduated at Yale (1804), was pastor of the Congregational church in South Britain, Conn. (1808–22), president of Dartmouth College (1822–28) and pastor of the Second Congregational Church, Portland, Me. (1828–33). He became professor of Christian theology in the seminary at East Windham (1833) and remained there until the day of his death. His 'Lectures on Theology' was published after his death by Rev. Dr. Gale, his son-in-law (Boston 1859). Consult Walker, W., 'New England Leaders' (New York 1901).

TYLER, Charles Mellen, American educator: b. Limington, Me., 1832. He was graduated at Yale in 1855 and later attended the divinity school there. He was ordained in the Congregational Church in 1857 and served as captain of volunteers during the Civil War. At its close he became pastor of the South Congregational Church, Chicago, and in 1873 he was called to the First Congregational Church of Ithaca, N. Y., where he remained till 1892, when he resigned to accept the appointment of Sage professor of history and philosophy of religion and Christian ethics at Cornell University, becoming professor emeritus in 1903. After 1907 he served as trustee of Cornell University. He published 'Bases of Christian Belief'; 'Life of George Wolcott, U. S. V.,' and last chapter of Pfleiderer's 'Geschichte der Religious Philosophie' and various articles in papers and magazines.

TYLER, Daniel, American soldier: b. Brooklyn, Conn., 7 Jan. 1799; d. New York, 30 Nov. 1882. He was graduated from West Point in 1819, served on garrison duty in New England in 1819–24 and was on duty in France in 1828–29 preparing a comprehensive work on 'Manœuvres of Artillery' and securing drawings and designs afterward used in modeling the United States artillery equipment. In 1834 he resigned from the army and was occupied as a railway constructing engineer and railroad president until the outbreak of the Civil War. He was appointed colonel and later brigadier-general of volunteers in 1861 and was in command of a division at Blackburn's Ford and at the first battle of Bull Run. He was mustered out of service 11 Aug. 1861, but was reappointed brigadier-general of volunteers 13 March 1862 and assigned to the Army of the Mississippi. He participated in the siege of Corinth, April–June 1862, and in June 1863 was in command at Harper's Ferry and Maryland Heights. In April 1864 he resigned his commission and subsequently established large cotton and iron industries in Alabama, was president of the Mobile and Montgomery Railroad in 1873–79 and also founded the town of Anniston, Ala.

TYLER, James Gale, American marine artist: b. Oswego, N. Y., 15 Feb. 1855. He was educated in the public schools of Oswego, N. Y., until 1870; studied for marine artist with A. Cary Smith, naval architect. He is represented in the collections of T. B. Clark, James Gordon Bennett, Catalin Lambert, A. K. Bolan, W. M. K. Alcott and many others. Among his most important pictures are 'The Half Moon'; 'The New World'; 'Norman's Woe'; 'Towing In the Prize'; 'Under Steerage'; 'Fortunes

of War'; 'The Mad Atlantic'; 'First American Shipwreck'; 'Flying Dutchman'; 'Abandoning the Jeannette,' etc. He has contributed illustrations and marine art studies to *Harper's, The Century, Truth* and other magazines.

TYLER, John, 10th President of the United States: b. Greenway, Charles City County, Va., 29 March 1790; d. Richmond, Va., 18 Jan. 1862. He was the second son of John Tyler, governor of Virginia (1808–11) and United States district judge (1812–13), and Mary Armistead, the only daughter and heiress of Robert Armistead. In early youth Tyler attended the school kept by Mr. McMurdo, a tyrannical Scotchman. Young Tyler at the age of 11 showed his independence and courage by crushing the autocratic schoolmaster's authority. In 1802 Tyler entered the grammar school of the College of William and Mary at Williamsburg, where he displayed an especial fondness for ancient history, Shakespeare's poetry and music. In 1807 he was graduated, and two years later was admitted to the bar. He was elected in 1811 to the State legislature, where he became a firm supporter of President Madison's war policy. One of his earliest public acts in this session occurred in connection with the United States Bank. The recharter of the bank was then before Congress and the Virginia assembly, in which State the bank was unpopular, instructed their senators, Richard Brent and William B. Giles, to vote against the recharter. Brent, however, voted in favor of the recharter and Giles voted in the negative, though contrary to his opinion and under protest. Accordingly, on 14 Jan. 1812, Tyler introduced resolutions of censure upon the course of the senators, asserting the Virginia doctrines as to the bank and the right of instruction. On 20 March 1813, Tyler married Letitia, daughter of Robert Christian. Her health was delicate. She died shortly after he became President. In 1844 Tyler married Miss Julia Gardiner. During the War of 1812 Tyler was called into the field at the head of a company of militia in defense of Richmond, then threatened by the British. From 1811 to November 1816 he served in the State legislature, when he was chosen to fill a vacancy in the House of Representatives. Here he became conspicuous as a strict constructionist Republican and States-Right advocate. He consistently opposed Calhoun's bill in favor of internal improvements, Clay's proposal for the recognition of the independence of the revolting Spanish-American colonies, a national bankrupt law, increased tariff duties and a bill for changing the per diem allowance of members of Congress to an annual salary of $1,500. He condemned, as arbitrary and insubordinate, the conduct of General Jackson in Florida, and delivered an elaborate speech against the national bank. In the 16th Congress, Tyler opposed the passage of the Missouri Compromise on the ground that Congress had no power to legislate for or against slavery in any Territory. In 1821 he declined re-election and retired to private life; but in 1823 he was again elected to the Virginia legislature. From 1825 to 1827 he served as governor of the State, when in the latter year he was elected United States senator to succeed John Randolph. In the Senate Tyler maintained an independent attitude although adhering to his strict constructionist principles. He voted against the "tariff of abominations" because he believed it was unconstitutional, and after taking part in the Virginia Constitutional Convention of 1829–30 he returned to the Senate, where he found himself first drawn to Jackson by the latter's veto of the Maysville turnpike bill. However, he displayed his independence by attacking Jackson's Turkish policy; approving Van Buren's appointment as Minister to Great Britain; supporting Jackson in the election of 1832 as the least "objectional candidate"; condemning South Carolina's nullification doctrines, while objecting to Jackson's proclamation of 10 Dec. 1832. The compromise tariff of 1833 caused by South Carolina's attitude was earnestly supported by Tyler; but on the "Force Bill," allowing the President extraordinary powers for the collection of duties, he was the only senator to vote in the negative. With the opening of Jackson's war on the United States Bank, Tyler broke with the administration and began to associate more closely with the opposition soon to be designated as the "Whigs." Tyler saw in the unbridled democracy of Jackson a tendency toward despotism "under the leadership of a headstrong and popular chief" and to him the "only safeguard for constitutional government lay in strict construction." Thus in the controversy over the removal of deposits from the United States Bank and with regard to Clay's resolution censuring Jackson for his course in this matter, Tyler voted with Clay and the bank men. In the election of 1836 Tyler was nominated by the "States-Rights-Whigs" for the Vice-Presidency on the ticket with Hugh L. White of Tennessee, and received 47 votes. Tyler's hostility to the Jackson party was emphasized when he resigned his seat because he could not conscientiously obey the instructions of the Democratic legislature of Virginia to vote in favor of Benton's resolution expunging from the Senate Journal the previous vote of censure. In January 1838 he was chosen president of the Virginia Colonization Society, and in the spring of the same year was returned to the Virginia legislature. The following year he made an unsuccessful attempt for the United States senatorship. The Whig Convention of 1839 nominated General Harrison for the Presidency in order to secure the votes of the anti-Masons and National Republicans, whom Clay had alienated, and Tyler was chosen as his running mate in order to obtain the votes of those Democrats who were dissatisfied with the administration. In the whirlwind campaign that followed Harrison and Tyler each secured 234 electoral votes and were elected. Harrison died one month after his inauguration and Tyler succeeded to his office. Immediately the President found himself in a conflict with Congress over the attempt to re-establish a national bank. Tyler had always held that Congress could not create a corporation within the State without the consent of the State. Therefore, Tyler vetoed the two bills presented to him as not incorporating his ideas, and after the second veto all the Cabinet members, except Webster, who was then negotiating the Webster-Ashburton Treaty, resigned. Thenceforth through-

out his administration Tyler was a President without a party and in constant strife with Congress. At the close of his term Texas was annexed, and this seemed to commend him for re-election; but in August 1844, after having been nominated at an irregular Democratic convention at Baltimore in May, Tyler withdrew from the race. From then until the Civil War Tyler held no public office, but when South Carolina adopted its ordinance of secession Tyler came forth as an advocate of peace and was chosen president of the Peace Convention which met in Washington, 4 Feb. 1861. Seeing the futility in getting Congress to accept the Peace Conventions resolutions, Tyler advocated the immediate secession of Virginia. In May 1861 he was elected a member of the provisional Congress of the Confederate States, and the following autumn was elected to the permanent Congress, but died before taking his seat. Consult Tyler, L. G., 'The Letters and Times of the Tylers' (3 vols., Richmond 1884), and Wise, H. A., 'Seven Decades of the Union' (Philadelphia 1872); Wilson, J. G., 'Presidents of the United States' (Vol. II, New York 1914).

R. C. McGRANE,
Assistant Professor of History, University of Cincinnati.

TYLER, John Mason, American biologist: b. Amherst, Mass., 18 May 1851. He was educated at Amherst (1873), received his A.M. degree there (1876), was at Union Theological Seminary (1874–76) and at Göttingen and Leipzig (1876–79). He was instructor in biology in Amherst (1879–81), and Stone professor in biology in that college since 1882. Among his publications are 'Man in the Light of Evolution' (1908), and 'Place of the Church in Evolution' (1914).

TYLER, Lyon Gardiner, American educator: b. Sherwood Forest, Va., August 1853. He is the son of President Tyler, and was graduated at the University of Virginia in 1875. In 1877 he became professor of *belles-lettres* at the College of William and Mary. In 1882–88 he practised law in Richmond, Va., and in 1888 was called to the presidency of the College of William and Mary. He has published 'The Letters and Times of the Tylers' (1884–85); 'Parties and Patronage in the United States' (1890); 'The Cradle of the Republic' (1900; 2d ed., 1906); 'England in America' (1904); 'Williamsburg, the Old Colonial Capital' (1907); 'The Cavalier in America' (1913). He edited 'Narrative of Early Virginia, 1606–1625' (1907); 'Men of Mark in Virginia' (5 vols.); 'Biographical Dictionary of Virginia' (5 vols., 1915).

TYLER, Moses Coit, American historian and scholar: b. Griswold, Conn., 2 Aug. 1835; d. Ithaca, N. Y., 28 Dec. 1900. He was graduated from Yale in 1857; later studied theology there and at Andover, and was pastor of the First Congregational Church, Poughkeepsie, N. Y., 1860–62. He was professor of English literature in the University of Michigan, 1867–81; literary editor of the *Christian Union* in 1872–74, and in 1881 was appointed professor of American history in Cornell University, which position he occupied at the time of his death. He was ordained deacon in the Protestant Episcopal Church in 1881 and priest in 1883. He published 'The Brawnville Papers' (1869); 'A History of American Literature During the Colonial Period' (1878); 'Manual of English Literature' (1879); 'Life of Patrick Henry' (1887); 'Three Men of Letters' (1894); 'The Literary History of the American Revolution' (1896). His 'History of American Literature' is a work of great literary charm and the most thorough scholarship. Consult Burr, G. L. (in 'Report' of the American Historical Association, Vol. I, New York 1901); Austen, J. T. (ed.), 'Moses Coit Tyler: Selections from his Letters and Diaries' (Garden City, N. Y., 1911); Trent, W. P. (in *The Forum,* New York, August 1901).

TYLER, Robert Ogden, American soldier: b. Greene County, N. Y., 22 Dec. 1831; d. Boston, 1 Dec. 1874. He was graduated at West Point in 1853, and until the outbreak of the Civil War served on frontier duty in the West. In April 1861 he accompanied an expedition for the relief of Fort Sumter. In May he was made assistant quartermaster with the rank of captain, and in September was appointed colonel of the Fourth Connecticut Volunteers (afterward First Connecticut Heavy Artillery), with which he served until the spring of 1862 in the defenses of Washington. He was conspicuously active in the Peninsula campaign of 1862, participating in its principal battles, and in November was promoted brigadier-general of volunteers. At Fredericksburg he commanded the artillery of the centre ground division. In recognition of his bravery in that action he was brevetted major in the regular army. He distinguished himself in the battles of Chancellorsville, Gettysburg and Spottsylvania; and was placed in command of the artillery reserve in the Army of the Potomac in November 1863. During the Spottsylvania action he repulsed an attack of Ewell's corps, and for this "gallant conduct and brilliant success" he and his men were publicly thanked by General Meade. He led a brigade at Cold Harbor, and there received a wound which maimed him for life and permanently broke his health. At the close of the war he was brevetted major-general in both the volunteer and regular armies.

TYLER, Royall, American jurist and author: b. Boston, Mass., 18 July 1757; d. Brattleboro, Vt., 16 Aug. 1826. In 1776 he was graduated at Harvard. He studied law under John Adams, was aide to General Lincoln for a short time in the Revolutionary War and afterward in Shays' Rebellion of 1786. He engaged in law practice at Guilford, Vt., in 1790, became judge of the Vermont Supreme Court in 1794 and in 1800–06 was chief justice. 'Reports of Cases in the Supreme Court of Vermont' (2 vols., 1809) constitute his only legal publication, but as a dramatist and a humorous writer he attained a considerable reputation. He was one of the first successful American playwrights, his plays including 'The Contrast' (1786); 'May-Day' (1787); 'The Georgia Spec' (1797), etc. He was a contributor of humorous prose and verse to the leading periodicals of his day, and also published 'The Algerine Captive' (1797); 'Moral Tales for American Youths' (1800); 'The Yankey in London' (1809), etc. 'The Contrast'

was republished in 1887 by the Dunlap Society. Some of Tyler's work appeared in *The Farmer's Museum* and *The Portfolio* of Joseph Dennie.

TYLER, Wat, English social reformer: b. Colchester, Essex; d. London, 1381. Nothing is known of his antecedents. There was serious cause for the rebellion which he headed, but like men of other ages he had ideas beyond his time, which he had imbibed from the teaching of a priest, John Ball (q.v.). The insurgents demanded the abolition of serfdom and the poll-tax, a maximum rent of four pence per acre for all lands freed from monastic or monarchial control, the right to buy and sell free from toll all over England, the abolition of the statutes of labor which favored landlords and master-craftsmen at the expense of the workingmen. There seems to have been a general spirit of discontent against all vested interests pervading the lower classes at the accession of Richard II—city corporations, monastic landholders, chartered corporations of all sorts. The young king paltered with Tyler and made promises which he afterward broke and the rebel leader was stabbed to death by Walworthe, mayor of London. This insurrection is an interesting incident in the history of the English people and cannot be treated as cavalierly as it used to be until about the middle of the 19th century when English historians began to apply themselves seriously to a study of their country's history as illustrated by original documents. Froissart and Walsingham deal unkindly and unfairly with Tyler, as might be expected since he opposed the clerics. Consult Trevelyan, 'England in the Age of Wycliffe' (1899); Powell, 'The Rising in East Anglia in 1381' (1896); Réville, 'Soulévement des travailleurs d'Angleterre en 1381' (Paris 1898); Hunt, W., and Poole, R. L., 'The Political History of England' (Vol. IV, London 1906); Oman, C., 'The Great Revolt of 1381' (Oxford 1906); Kriehm, George (in *American Historical Review,* Vol. VII, New York 1902).

TYLER, Tex., city, county-seat of Smith County, on the International and Great Northern, the Saint Louis Southwestern railroads, also a branch to Lufkin in Angelina County; about 95 miles east by south of Dallas. The city is on the highest point of land between the Gulf of Mexico and the Red River and is in a fertile agricultural region. The chief manufacturing establishments are a box factory, brick works, pottery, canning factory, ice factory, oil mills, mattress and overall factory, "Cotton Belt" railroad shops, general offices, waterworks, electric-light plant, telephone works. The last census reported 20 industrial establishments, employing 592 persons, with a capital of $686,000 invested, paying $391,000 in services, $449,000 for raw materials and turning out products valued at $897,000. The shipments are chiefly cotton, corn, fruits, vegetables, hay and livestock. There are several churches. The educational institutions are Tyler College, Tyler High School, Hubbard, Marsh and Douglas public schools, two public schools for colored pupils and East Texas College for colored pupils. The four banks have a combined capital of $600,000. and the average annual amount of business is $50,000,000. The government is of the commission form since 1914. Tyler was settled in 1846, incorporated the same year and chartered as a city in 1875. Pop. 11,629.

TYLOPODA, a group of ungulate mammals, containing the camels and llamas, an ancient group characterized especially by the structure of the feet, in which no traces of the second and fifth toes remain, and the fused metacarpals and metatarsals diverge somewhat at the distal ends. The tread is formed by solepads. Singular peculiarities are the elliptical shape of the blood corpuscles and the character of the rumen-chamber of the stomach. See CAMELIDÆ.

TYLOR, tī'lôr, **Sir Edward Burnett,** English anthropologist: b. Camberwell, London, 2 Oct. 1832; d. 2 Jan. 1917. He was educated at the Friends' School, Tottenham, and in 1856 accompanied the ethnologist Henry Christy on a scientific journey through Mexico, one result of which was his 'Anahuac or Mexico and the Mexicans' (1861). He was appointed keeper of the Oxford University Museum in 1883 and became professor of anthropology there in 1895. He was knighted in 1912. In 1888 he was Gifford lecturer at Aberdeen and became president of the Anthropological Society in 1891. He has published in addition to the work already named 'Researches Into the Early History of Mankind' (1865); 'Primitive Culture' (1871; 3d ed., 1891); 'Anthropology' (1881); 'The Natural History Religion' (1900). His works gave a great impetus to anthropological science. Tylor is perhaps best remembered for his statement and development of the proposition that animism is an unusual factor in primitive religion.

TYMPANUM. See EAR.

TYNAN, Katherine. See HINKSON, KATHERINE TYNAN.

TYNDALE, tĭn'dąl, **Hector,** American soldier: b. Philadelphia, 24 March 1821; d. there, 19 March 1880. He was engaged in business in his native city during the events just preceding the Civil War. With John Brown and his raid in Virginia he had no connection; but on the last visit of Mrs. Brown to her husband Tyndale consented, at the risk of his life, to act as her escort, a duty which, in the face of insult and violence, he unflinchingly performed. At the outbreak of the war he was in Europe, but at once returned and entered the army as major of the 28th Pennsylvania regiment. In April 1862 he was promoted lieutenant-colonel. At Antietam he commanded a brigade, with which he three times repulsed Confederate assaults. Early in the day he was badly wounded, but remained on the field for hours, being finally carried, with a second wound, to the rear. In November 1862 he was made brigadier-general of volunteers for gallantry in that battle. At Wauhatchie by a bayonet charge he captured a hill which was later named Tyndale's Hill. He also took part in a number of battles around Chattanooga. In 1865 he was brevetted major-general. He was a Republican nominee for mayor of Philadelphia in 1868, and was defeated by only 68 votes out of more than 120,000.

TYNDALE, William. See TINDALL, WILLIAM.

TYNDALL, tĭn'dąl, **John,** British physicist: b. Leighlin Bridge, County Carlow, Ireland,

21 Aug. 1820; d. Haslemere, Surrey, 4 Dec. 1893. After secondary schooling he joined the Ordnance Survey, with which he was connected for five years. He was then engaged in railway work, and in 1847 became a teacher of physics at Queenwood College, Hants. After studying in Berlin and becoming acquainted with Faraday, Huxley and other eminent men, he was appointed professor of physics in the Royal Institution, London, with which he continued to be connected till his retirement in 1887. Tyndall did a vast amount of valuable work by original investigation in various branches of science, especially magnetism, electricity, heat, light and sound, on which he published many papers and several well-known volumes. Among these are 'Notes of a Course of Nine Lectures on Light' (1870); 'Notes of a Course of Seven Lectures on Electrical Phenomena' (1870); 'Contributions to Molecular Physics in the Domain of Radiant Heat' (1872); 'On the Transmission of Sound by the Atmosphere' (1874); 'Free Molecules and Radiant Heat' ('Philosophical Transactions,' 1882). He made, also, studies of glacial phenomena. In 1872–73 he lectured in the United States, and in 1873 published 'Six Lectures on Light, Delivered in America.' He was president of the British Association meeting at Belfast in 1874 and delivered an eloquent address, which, by its materialistic tendency, aroused much controversy. He was the recipient of numerous honors from learned bodies at home and abroad, and many of his books were translated. His ability as a speaker fitted him to be a popular expounder of complicated problems in modern physical science.

TYNE, tīn, England, a northern river formed by the junction of the North and South Tyne, rising in Northumberland and Cumberland counties. As a united river it flows by Newcastle and empties into the North Sea at Tynemouth, after a course of 120 miles. It is partly tidal and belongs to the richest coal region of England. Its principal tributaries are the Derwent and Team. The chief towns are Corbridge, Ovingham, Newburn, Newcastle, Gateshead, Jarrow, Tynemouth, North and South Shields (qq.v.). It is navigable above Newcastle. Ship-building is important, and the Tyne is celebrated for its boat races. Many manufactures are carried on along its banks. Many improvements have been made by the building of long piers and the deepening of the channel, giving an impetus to trade. Consult Guthrie, 'The River Tyne' (Newcastle 1880), and Palmer, 'The Tyne and its Tributaries' (London 1881).

TYNEMOUTH, tīn'mŭth or tīn'mŭth, England, a municipal and Parliamentary borough in Northumberland, at the mouth of the Tyne on its north bank about eight miles east of Newcastle. It is a favorite watering-place and a fine promenade, park and winter garden have been laid out along the beach. There are many handsome buildings in the town, including Tynemouth Palace and a picturesque old priory, the Master Mariners' Asylum, aquarium, assembly-rooms, etc. The borough includes the towns of North Shields, Chirton, Cullercoats and Preston. The clearings at the port amount to 1,500,000 tons annually and there is a large export trade in coal and coke. Pop. 58,800. Consult Adamson, 'Tynemouth Priory and Castle' (in Archæologia Ælina, Vol. XXIII, London 1901).

TYNER, tī'nėr, **James Noble**, American lawyer: b. Brookville, Ind., 17 Jan. 1826; d. Washington, D. C., 5 Dec. 1904. He was admitted to the bar of Indiana, but later gave up his practice to enter political life. In 1869 he was elected to Congress from Indiana, and served until 1875, when he was appointed Postmaster-General. He remained in the Cabinet until 1882. In 1889 he was made assistant Attorney-General for the Post Office Department, in which capacity he served until 1893. Four years later he was reappointed to this office, but resigned in 1903.

TYNG, Stephen Higginson, American Protestant Episcopal clergyman: b. Newburyport, Mass., 1 March 1800; d. Irvington, N. Y., 4 Sept. 1885. He was graduated from Harvard in 1817, was in mercantile pursuits in 1817–19 and in 1819 began the study of theology with Bishop A. V. Griswold (q.v.). He was ordained in 1821, and was minister of Saint George's, Georgetown, D. C., in 1821–23 and of Queen Anne's parish, Prince George County, Md., in 1823–29. From 1829 to 1833 he was rector of Saint Paul's, Philadelphia, from 1833 to 1845 of the church of the Epiphany there. He held the rectorship of Saint George's, New York, from 1845 until his retirement as pastor emeritus in 1878. He was well known for his eloquence in the pulpit and on the platform. His theology was strongly evangelical, and he was a prominent opponent of ritualism in his Church. He also advocated total abstinence, and was otherwise identified with reform interests. Besides editing successively *The Episcopal Recorder, The Theological Repository* and *The Protestant Churchman*, he published several volumes, including collections of sermons and addresses and 'Recollections of England' (1847); 'Forty Years' Experience in Sunday Schools' (1860); 'The Prayer Book Illustrated by Scripture' (3 series 1863–67), and 'The Office and Duty of the Christian Pastor' (1874). Consult the 'Life' by his son, C. R. Tyng (New York 1890).

TYPE. See PRINTING.

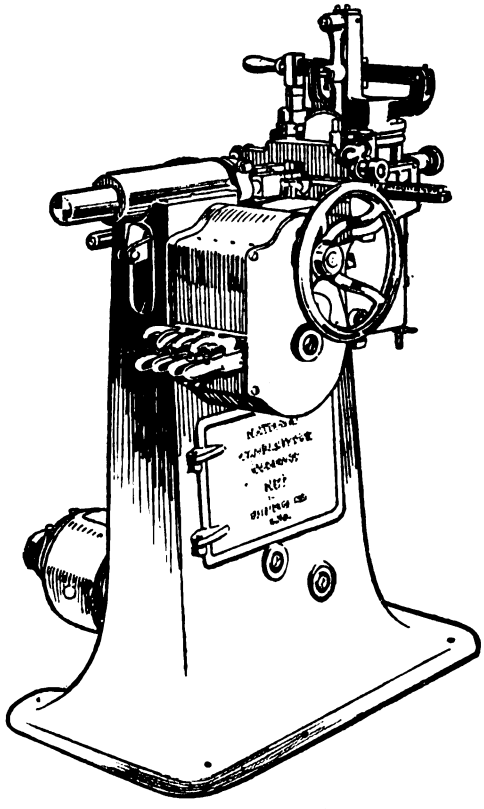
TYPE-CASTING MACHINES. Every book, news and job-printing office in former years has been absolutely dependent on the type-founder, with his elaborate plant and his established fonts of type in standard and individual copyrighted faces. The waste and wear was large and costly. Office economics compelled the use of fonts even after the faces of many of the types had become too battered for clean printing. To replace the broken and battered type it was necessary to send to the foundry for «sorts» (as the individual types are called) to fill out the fonts, and this was not only expensive but unsatisfactory, because it resulted in mixing new type with the old. The invention of the Mergenthäler Linotype machine enabled the printing offices to present absolutely clear-faced, freshly-cast body type for newspapers, books, pamphlets and the like. To a degree, also, headline type for newspapers could be economically set up and a considerable proportion of the advertising display. But there still remained a demand for movable type for hand

use. To effect the economy demanded, a small, compact machine, a sorts caster, to cast individual type of any face and size at the pleasure and convenience of each office, was devised and several different makes are now in successful operation in many newspaper, book and job-printing offices, one being the invention of J. S. Thompson, another of Hanrahan, Brown and Boydon.

The sorts caster occupies but little space — four and one-half feet high by three and one-half feet long by three feet wide. It is operated by belt and pulley and requires one-fourth horse power. Carrying to the full the newly-adopted standardization of type, one size of the machine will cast with accuracy type from 6-point up to and including 36-point, and a larger size type from 36-point to 72-point.

A very solid cast-iron frame supports the strongly made component parts — an adjustable steel mold to which is fastened the brass matrix of the desired letter; a gas-heated pot of molten type metal; a plunger rod to force accurately the exact amount of molten metal into the mold as the latter is automatically thrust forward into place, and a planer to trim the base of the type and eject it, perfect and complete, along on the delivery rod when mold and melting pot separate.

The base of the mold is stationary and permanently secured to the machine and forms with the ejector rod two sides of the mold. These are so arranged as to receive interchangeable insert mold parts to complete the exact parallelogram required by the particular face and size of the type to be cast. This insert mold part carries the brass matrix in which is cut the face of the type. Each matrix specifies the exact adjustment of blanks which the operator must make to procure the correct width or set-wise size of the character to be cast. There is an insert mold part for each body-wise size.



A Sorts Caster Machine.

A 50-pound font of 12-point type can be cast in nine hours and a font of 18-point in seven. Fonts of matrices are sold outright; distinctive designs may be cut for individual printers, or fonts may be hired as books are from a circulating library.

TYPE-COMPOSING MACHINES. See COMPOSING MACHINES.

TYPE METAL. See TYPE AND TYPE-FOUNDING.

TYPE-SETTING MACHINES. See COMPOSING MACHINES.

TYPE AND TYPE-FOUNDING. A type for printing is a letter or character in reverse, which is inked and impressed on paper to print. Type are ordinarily made of a composition of lead, tin and antimony, lead predominating. A common formula is: lead 10, antimony 4 and tin 2. The addition of antimony serves to harden the type and tin toughens it, while the proportion of the three is designed to obviate shrinkage in casting. Very large type are cut out of hard wood, with a pantagraph machine. Type are now made to a uniform height, which is a little under an inch, and are cast so exactly that thousands of them are combined in lines, pages and forms and wedged together solidly in a chase or frame and placed on the bed of a press for printing. Early printers had to cast their own type by throwing the hot molten metal into hand moulds. Hand casting was abandoned about 1845 and the Bruce type-casting machines were generally adopted in American type-foundries. These cast the type with a jet or sprue that had to be broken off, after which the type was smoothed by rubbing on a stone to remove the bur or rough edges. About 1890 automatic Barth type-casting machines came into use, delivering a completed type, and these have displaced the hand-machines. The standard machines are used to cast body type, as from 5- to 12-point. (See PRINTING for description of type sizes). There are also machines that cast job or display type and one of these also sets the type. See COMPOSING MACHINES.

Type-founding begins with designing the letters, which are drawn to a very large scale. Permanent dies are made from these drawings and these dies are used to guide the cutters of a punch-cutting machine, which form characters or letters in steel that is afterward hardened. These punches look like type but have usually a long shank. They are used to drive into softer metal to form a matrix, which matrix is later to form one end of a mold in which the type is cast. A mold of a given size may be used to cast any type of that size, if the appropriate matrix of the desired letter is introduced. The form of a matrix is that of a letter or printed character, but the type itself is a reverse form. The type proper is made rectangular and is nicked on the front

or lower side to assist the compositor in placing it in correct position. The position of the nick or number of nicks also serves to distinguish the type of different fonts of the same size. There is usually a groove across the foot to take out any irregularity in breaking off from the sprue; also a pin-mark on one side. The top or printing surface of the type is called the "face" and the beveled side of this face is the "beard," the beveling permitting easy withdrawal from the matrix. When a type-face is in high relief it is said to have a deep "counter." The horizontal hair-lines, which are conspicuous on the H, F, M, etc., are termed "serifs." A part that hangs over the body, as in some f's and j's, is a "kern." Blank types, below type high, are called "quadrats" or "quads," but when less than an n in width are termed "spaces." The "body" of a type is the size of the shank and the standard sizes are measured by "points." (See PRINTING). A point is one-seventy-second of an inch, and 12-point and "pica" are now identical. The point and the pica are the units of measurement, together with the m. This m is spelled "em" and is assumed to be square in body, as wide as it is high. One thousand ems is the unit by which type composition is paid. The price of type composition has varied all the way between 25 cents and $1 per thousand ems.

Type are made in an infinity of styles or faces, the most common of which are shown below:

This line is set in De Vinne.

Type that is broad for its height is termed "fat" and when narrow for its height is "lean." A font or "fount" of type is a complete assortment of one kind. As more e's are used than any other letter, these are the most numerous in a font, being followed by t, a, o, i, n, etc. An ordinary font contains capitals, lower case, figures, points, spaces and quads and some signs or reference marks, as $, &, *. It may also contain italic, small caps, fraction-marks, accented letters, logotypes, etc. The printer's case is usually made as a pair, the lower case letters, figures, points and spaces being in the lower case of the pair and the capitals and small capitals and signs, etc., in the upper case. Hence capitals are sometimes called "upper case."

The first English type-founder of ability was John Day (1522–84), who made type only for his own printing office. Benjamin Sympson (1597), of London, was the first English founder to make type for the printing trade. He was followed by John Grismand, Thomas Wright, Arthur Nichols and Alexander Fifield. Joseph Moxon was the most distinguished of the early English founders, and flourished from 1659 to 1683. He published the first book which describes type-founding, 'Mechanick Exercises' (1683), a reprint of which may be found in many large libraries. William Caslon (1692–1766), of London, was the most conspicuous founder of the 18th century and laid the designs of some of the best modern faces. After him came John Baskerville, Alexander Wilson, Thomas Cottrell, Joseph Fry, Joseph Jackson, Robert and William Martin, Vincent Figgins, William Miller, Anthony Bessemer, all of Great Britain. In the United States, Abel Buell, of Connecticut, is mentioned by De Vinne as being probably the first founder, in 1769. The early founders were also stereotypers. It was in 1772 that Christopher Sauer (or Sower) established a type-foundry at Germantown. Benjamin Franklin established his Philadelphia printing office with type bought of P. S. Fournier, the French founder who is credited with originating the point system. Later Franklin cast his own type in a small way. John Baine, of Glasgow, came to Philadelphia, in 1875, and started a foundry. Adam G. Moppa established the first foundry in New York about 1791, but later went to work for Binny and Ronaldson, who began type-founding in Philadelphia in 1796. In 1833 this was taken over by Johnson and Smith and finally became the well-known house of MacKellar, Smith and Jordan. White and Wing started in Hartford in 1804, but discontinued. White going to New York in 1810. In 1854 White and Company sold out to Farmer, Little and Company. Robert Lothian made type in a small way in New York early in the 19th century. James Conner established himself originally as a stereotyper in New York in 1827 and later took up type-founding. William Hagar's foundry was started in New York in 1840. David Bruce (1770–1857), followed by George Bruce and David Bruce, Jr., conducted a type-foundry in New York from 1806 until 1890. David Bruce, Sr., invented the "patent block" for stereotypes and David Bruce, Jr., the first real type-casting machine. James Lindsay and Peter C. Cortelyou were associated with the Bruces. Samuel N. Dickinson and Michael Dalton were the most conspicuous Boston founders in the last century. The Cincinnati type-foundry was established in 1817, the Saint Louis foundry in 1840. Faulkner and Son established a foundry in San Francisco in 1866 and Painter and Son in 1868. Collins and McLeester began in Philadelphia in 1853, Barnhart Brothers and Spindler were established in Chicago in 1878 and later in Saint Louis, Omaha, Kansas City and Saint Paul. Marder, Luse and Company started in Chicago in 1855 and later they had a foundry in San Francisco. Shraubstadter and Saint John started the Central Type Foundry in Saint Louis in 1875; the Cleveland foundry was established in 1879. The multiplication of type-foundries in the United States entailed great duplication of costs in producing new type faces. These and other conditions induced the formation in 1892 of the American Type Founders Company, which took over 23 of the leading firms and corporations in type-founding in America. This has been commonly referred to as the Type Trust, but it never monopolized the business and independent foundries have been maintained in most large cities. Early in the 20th century the widespread use of the linotype machine took away from the type-foundries a large part

of the trade that would otherwise have existed in individual type. Then the monotype and several type-casting machines came into use in large printeries, which now cast a great deal of their own type. The business of the type-foundries, thus reduced, has changed and they now handle a great variety of printers' supplies and small mechanism. Consult Pasko, 'Dictionary of American Printing' (1892); De Vinne, 'Plain Printing Types' (1900).

CHARLES H. COCHRANE,
Former Secretary, Typothetæ of New York.

TYPEE. 'Typee: a Peep at Polynesian Life,' which Herman Melville published in 1846, was the earliest notable romance dealing with the South Seas, a region abundantly exploited by romancers since. Melville had visited the Marquesas in the summer of 1842 as a sailor before the mast on the whaling-ship *Acushnet*, had escaped with a companion to the island of Nukuheva [Nukahiva], and had strayed into the cannibal valley of Typee [Taipi], where the savages held him for four months in an "indulgent captivity." Although he kept no journal and wrote nothing down for three years, he followed his memories closely; but of few writers is it more difficult to say than of Melville at what point fact shades into fiction. Merely as history 'Typee' has real value, with its sympathetic yet sharp-eyed observation of Marquesan customs and its rich descriptions. It is, however, as fiction that the book has been primarily influential and generally read, as a romance of the life led by a sophisticated man among perilous, lovely, barbaric surroundings. The valley of Taipi becomes, in Melville's handling, a region of dreams and languor which stir the senses with the fragrance and color of the landscape and the gay beauty of the brown cannibal girls, especially of Fayaway, the dainty, memorable heroine. Yet Melville, though thoroughly sensitive to the felicities of the exotic life, never loses himself in it entirely, as did later men like Lafcadio Hearn and Pierre Loti, but remains always the shrewd and smiling Yankee. (He later continued the narrative in a sequel, 'Omoo,' q.v.).

CARL VAN DOREN.

TYPEWRITER, a machine operated by means of a manual keyboard, which produces characters resembling those of ordinary letter press, as a substitute for handwriting, by the impress of type.

History.— The first successful typewriter was an American invention, and was so far perfected in the late seventies of the 19th century that many thousands were then being made to supply the demand. The archives of the British Patent Office show that in 1714 a patent for a writing machine — the first typewriter known — was applied for by Henry Mill, a London engineer. No drawing of his machine is extant, and its construction is not known. In 1784 a French invention appeared, designed to make embossed or raised characters for the blind. In 1829, W. A. Burt patented the first American machine. A French machine of 1833 was provided with the first manual keyboard. In 1843, Charles Thurber, then of Worcester, Mass., secured a patent for a typewriter, and two years later a second patent, but his machines were never perfected for practical use. About this period Sir Charles Wheatstone invented several writing machines, the models of which repose in the South Kensington Museum. The year 1855 saw the production of Foucault's writing machine for the blind. Indeed most of the efforts of early inventors were directed to producing machines for the use of the blind, and embossed characters were general.

In 1856, Alfred E. Beach, of New York, one of the proprietors of the *Scientific American*, secured a patent for a typewriter which embodied the characteristic basket-like disposition of type-bars and type used on the standard machines of to-day. The Beach machine was for printing embossed letters for the blind. Contemporaneous with this inventor, Dr. S. W. Francis, of New York, was working on the same line. He arranged his keys in a circle around the instrument, used an inking ribbon, a traveling paper-frame and an alarm-bell, rung as the end of the line was approached, thus embodying many features of present-day instruments. Thomas Hall, of New York (inventor of the Florence sewing-machine), also was experimenting on a typewriter about this time. In 1859 he learned of the prior patents and tried to purchase them. In June 1867 he obtained a patent of his own; and one of his machines, printing large and small letters, was shown at the Paris Exposition of 1867. The paper was placed on a table, which slid under the bottom of the machine. The spacing for letters varied with their thickness, thus producing work more resembling that of type than does the identically spaced typewriting of recent machines. Hall struggled against much discouragement, and never succeeded in bringing his machine into use. In 1881 he secured a patent on another type of machine, with a perforated dial-plate and rubber cylinder. It achieved a partial success, but of late years it has been turned out in cheap form as a toy. John Pratt, of Center, Ala., secured a United States patent in 1868 for what he called his Pterotype — a complicated machine which did not come into public use. This brings us to the recent history of the typewriter in which it was brought to the high degree of efficiency we witness to-day. Charles Latham Sholes, of Milwaukee, Wis., with Samuel W. Soule and Carlos Glidden, became associated: the first two were trying to construct a numbering machine and Glidden suggested developing the idea into a typewriter. After months of work Sholes left the others, and with James Densmore, of Meadville, Pa., as financial backer, pushed the invention to completion, and secured a patent in June 1868. In 1873 it was put on the market as the Sholes and Glidden typewriter. E. Remington and Sons, of Ilion, N. Y., became the manufacturers of the machine and, in 1874, 400 were sold. These early machines printed only one kind of letter so that the writing was in capitals only. The introduction of small letters occurred in 1877 and many minor improvements were added from time to time. As this machine, the first which proved a commercial success, embodies most of the fundamental elements of present-day machines, an enumeration of these will not be amiss. The Remington, as it is now known, is characterized by the "shift," by which the

same keys print large or small letters as desired. The radial type-bars, forming when at rest a sort of basket, form another common feature. On the top of the frame is a roller covered with India-rubber; and by its side and parallel, a smaller roller. Between these the top edge of a sheet of paper is inserted, and brought into proper position to receive the first line of "writing." Immediately in front of the rubber cylinder (in the "visible writers"), beneath (in the "invisible writers"), and in line with its axis, is the ink-ribbon; and in front of the ribbon at a point in the centre every letter is made to appear in succession to do the writing. The ink-ribbon is automatically raised in front of the type-bar when a key is depressed, and falls back to its original position as the bar recedes, this permitting the typist to see the impression on the paper. During operation the ribbon is gradually unwound from a spool or holder at one side of the machine on to another at the opposite side; the movement of the ribbon may be reversed at will. The carriage with the platen moves along one space to the left as each key is released. This movement and stoppage is regulated by a coiled spring and strap, and a ratchet escapement. For tabulation special column stops are set at the desired distance and upon depressing the tabulár key the carriage advances to the left until the next column stop is reached. The types are usually of steel or some hard alloy and are fixed in the ends of a series of levers, each lever having its fulcrum at a point in the circumference of the central opening. The key for forming the spaces between the words extends nearly the whole length of the keyboard, so that it can be readily worked, no matter in what position the hands may be at the close of every word. The depression of each key causes the letter with which it is connected to strike the ink-ribbon, thereby transferring the form of the letter to the paper. On removal of the pressure, the type descends by its own gravity.

The Caligraph, invented and developed by George W. N. Yost, uses no shift, but has a separate key for each character. In February 1880 a patent for a typewriter was granted James B. Hammond, of New York. The type-faces were carried on the periphery of sectors of circles. These were slipped on a vertical pin and rotated around it. Three such sectors gave three sets of types, thrown into action by two "shifts." Instead of striking the type against the ribbon and paper, a hammer gave the paper a blow from the back against the ribbon and type-face. The force of the blow came from a spring, so that an even force was always secured. Other classes of machines have no ribbon, but use an inking pad. Of these the Yost was the most successful. In 1889 arrived the Smith-Premier machine — a double keyboard type-bar machine. It made use of a tri-colored ink-ribbon. The Blickensderfer machine of the type-wheel class entered the field in 1892 and attained great popularity. After a period its backers put out an electric machine which rendered operation very easy. From 1890 to 1905 over 100 new machines were brought out, but few had any distinguishing merit and after a brief career the market was left to the older and standard machines. An exception to this was the Underwood machine of the type-bar class, a "visible" writer from the start. This machine is a great favorite with typists because of the ease of manipulation and the high quality of the work. The L. C. Smith machine also proved of enduring quality. Ball-bearings were used to secure smoothness and ease in running. Other more or less successful machines are the Oliver, Royal and Monarch. The Oliver can scarcely be called a "visible writer" since only one-third of the line of writing can be seen. This machine has a "double shift" system for which the advantage is claimed that a smaller and simpler keyboard is rendered possible thereby.

Within recent years writing-machines have been developed for writing on flat cardboards, on a book such as a ledger, to make out bills, tabulate, discount and add several columns of figures. The Elliott-Fisher, the earliest and one of the best of these machines, has a flat platen, about which the machine proper may be moved up or down, right or left, etc. Bookkeeping and adding typewriters have also been put on the market by the makers of standard writing-machines such as the Remington and Underwood companies. They have done much to remove the drudgery from bookkeeping and accounting.

The typewriter became a favorite soon after its introduction in the seventies. It is now regarded as an essential part of all office equipment and even in the home it is coming into general use. Portable machines of excellent quality have made it available for travelers, army officers in the field, etc. Magazines and other periodicals are practically a unit in demanding typewritten "copy" from their correspondents and contributors, because of its greater legibility. As regards speed, a rate of 60 words a minute is good ordinary work and is about three times faster than a good penman, a rate of 80–90 words is fast average, while 100 words or over per minute is considered very fast. The record in competition is 143 words per minute. A recent invention is a typewriter with telegraphic attachment, which makes it possible for an operator to type a message, for instance, in Montreal, and a receiving machine in New York prints the message on a paper after the manner of the ordinary machine. The Patent Office reported on 9 Oct. 1919 that it had issued approximately 7,006 patents covering typewriting machines.

Statistics.— Too frequently official statistics include the incidentals under "Typewriters and Supplies." Below are the latest available figures:

Year	Establishments	Typewriters and supplies value
1914	107	$30,988,000
1909	89	26,309,000
1904	66	16,642,000
1899	47	8,400,000
1889	30	1,422,000

These establishments or factories were located in the States as follows: Connecticut,

7; New Jersey, 8; New York, 61; other States, 31. In the year 1914 typewriter machines were being produced in 50 establishments with an invested capital of $27,635,000, with an output valued at $19,851,000 and giving employment to 12,654 wage-earners. The following are the export values of typewriters in recent years: 1908, $6,495,756; 1909, $6,899,069; 1910, $8,239,510; 1911, $9,778,498; 1912, $11,423,691; 1913, $11,532,364; 1914, $10,575,573; 1915, $5,315,134; 1916, $9,104,189; 1917, $11,162,423; 1918 $7,480,714. The sudden fall in exports after 1914 is, of course, a reflection of the war cutting off Europe from the American product as well as shortage of ships and contracted credits in neutral countries.

TYPHA, the cat-tails or bulrushes, a genus of perennials growing in swamps, the somewhat sword-shaped bases of the leaves often submerged. The leaves of *T. latifolia* are radical, long and linear; the flowers are monœcious in a cylindrical spike, terminating a tall stem and subtended by fugacious bracts. The perianth consists of bristles, with stamens or ovary according to sex; the staminate flowers are at the apex of the stem and after pollinating gradually disappear, leaving the lower fertile ones to mature their fruits. When ripe, these fruits form decorative cylindrical masses, of a handsome seal-brown color, at the level of, or a little higher than, the tops of the leaves. During the winter these spikes disintegrate and the nut-like fruits float away, supported by the white hairs expanding at their bases. The smaller species (*T. angustifolia*) has spikes in which the staminate and pistillate portions are slightly separated. Both are widely distributed. As is the case also with the western American species, the abundant mealy pollen of *T. elephantina,* or elephant-grass, serves for bread in India and New Zealand and also as a substitute for matches and tinder, since it is very inflammable. The plant is a favorite food of elephants. *Typha* rhizomes abound in starch and when rid of their acridity become a food of various peoples; they have also been employed as an astringent and diuretic drug, and the down of the fruits serves as a dressing for wounds and for upholstering purposes. See BULRUSH; TULE.

TYPHOID BACILLUS. This bacillus, the cause of typhoid fever, was first discovered by Eberth in 1880. He found it in the glands of the mesentery and in the spleen. It was not until 1884, however, that Gaffky obtained the organism in pure culture. He first used a potato culture-medium and was fortunate in obtaining the organism, for since its discovery it is becoming more and more evident that the typhoid bacillus is very closely allied to a great variety of other forms and it is now necessary to use a very complicated technique in order to separate this form from a number of allies. One form, the *Bacillus coli commune,* or colon bacillus, a constant inhabitant of the intestinal canal, resembles the typhoid bacillus so closely that as late as 1890 no less an authority than Koch declared that a sure means of differentiation between the typhoid and colon bacillus had not been discovered. Since then, however, work by a number of bacteriologists, Pfeffer, Wassermann, Löffler, Abel, Hiss and others, has given a series of distinguishing signs, so that at the present time it is possible to make a definite separation of the typhoid organism from all others. The typhoid bacillus is a short comparatively plump rod varying in length from $\frac{1}{2000}$ to $\frac{1}{8000}$ of an inch and in width from $\frac{1}{5000}$ to $\frac{1}{8000}$ of an inch. It has a number of flagella (10 to 12) which enable it to move. The marked motility of the typhoid bacillus is of much importance in the study of this form since the so-called blood-test or Widal's test for typhoid depends on a change in this characteristic. For the details of its cultural characters standard works on bacteriology should be consulted but it is of importance from the standpoint of sanitary science and preventive medicine (q.v.) to realize that the typhoid bacillus is capable of growing for a time at least in many different foods and drinks, particularly in milk and in water. Every patient with typhoid fever is constantly giving off millions of these small bacteria in stools and in urine. From these two main sources the great danger in typhoid contagion comes, for soiled fingers of chambermaids, flies, household implements may all prove intermediaries in conveying the bacilli to food and thence into the digestive canal of a well person. Or the fæces and urine may soak into a well or other source of drinking-water supply, and thus be the means of causing extensive epidemics. Contagion by uncleanliness and lack of care in disinfecting the stools and urine is responsible for most cases of typhoid fever. Destroy the bacillus by heat or by proper chemical means and typhoid fever will disappear. (See BACTERIA; TYPHOID FEVER). Consult Muir and Ritchie, 'Manual of Bacteriology'; Kolle and Wassermann, 'Handbuch der pathogene Mikroorganismen' (1902–04); Osler, W., 'Problems of Typhoid Fever in the United States' (Baltimore 1899); id., 'Studies in Typhoid Fevers' (ib. 1895); 'Public Health Report, No. 56' (Washington 1911); 'Reference Handbook of the Medical Sciences' (1915); Whipple, J. G., 'Typhoid Fever: Its Causation, Transmission and Prevention' (New York 1908).

TYPHOID FEVER, or **ENTERIC FEVER,** a specific continued fever of long duration and communicable, due to the *Bacillus typhosus* or Eberth's bacillus. It is usually attended with diarrhœa, sometimes with an eruption and is characterized by inflammation and ulceration of Peyer's patches (q.v.) in the small intestine, by enlargement of the spleen and mesenteric glands and catarrhal inflammation of the intestinal mucous membrane. It is one of the exanthemata (q.v.). This fever was called typhoid and at one time abdominal typhus, from its supposed resemblance to typhus fever (q.v.). It has also been known as low and as slow fever and as autumnal or fall fever. It is considered to be a preventable disease, yet it prevails frequently as an endemic and epidemic, especially in large cities, destroying many lives. It occurs most often in the fall and early winter and mostly between the ages of 18 and 45, when men especially are less prudent and run more to excesses than at other periods of life. Improper dwellings and bad sanitary environments, excess in eating and drinking, want of sleep and too much mental work — by these the vitality is undermined, predisposes persons even in the prime of life to the onset of typhoid, especially if it be prevailing in their community. It is believed

that the blood of such persons has undergone some chemical change which has diminished its bactericidal quality and so lowered its inherent power of resistance to disease. It is not very uncommon to find cases of "walking typhoid," i.e., persons not sick but having a temperature of 102° to 104°, especially toward evening.

Typhoid fever is frequently, if not always, a septicæmic disease and its range of infectivity is greater than is usually supposed. The bacillus has been found in the blood, urine, fæces and sputum. Milk, vegetables, flies, oysters, etc., are bearers of the germs, while the bacilli may be conveyed by air to the respiratory mucous membrane and their initial colonization take place there rather than in the gastro-intestinal tract. Typhoid fever like cholera is considered as "ingestion infection" and both are disseminated from the excreta, vomit and perhaps sputum. But drinking water polluted by the bacilli through infected sewage, etc., is the most frequent cause of typhoid infection. Germs from a single case of typhoid may find their way into springs and other sources of water supply and cause widespread dissemination of the disease. The epidemics in Lausanne, Switzerland (1872), Chicago and Philadelphia (1890–1900) and Ithaca, N. Y. (1903), are examples of typhoid outbreaks caused by polluted water. "In Vienna, when for a period the water supply from guarded springs was turned into the city, typhoid which had persisted in epidemic form for years almost entirely disappeared and when as the drier season advanced this purer supply was insufficient and the water of the Danube was again turned on the scourge broke out with renewed violence but in those parts of the city supplied by river-water. This experience was repeated in Paris and it is practically true of every city supplied with drinking water from exposed streams and lakes." Freezing does not sterilize water so that contaminated ice used in drinking fluids or coming in direct contact with food is a source of infection. The boiling of water is a safeguard while filtration is not trustworthy in the elimination of infective organisms. Next to infected drinking water infected milk is the most common cause of typhoid through the polluted hands of milkers or from the washing of receptacles for milk in cold water polluted by typhoid discharges. Such vessels should be thoroughly scalded. The ingestion of uncooked articles of food and especially of salad vegetables — lettuce, celery, etc.— raised in ground fertilized by infected sewage, is a source of infection, as is the ingestion of oysters and clams grown in water similarly contaminated. Dust carrying typhoid germs, if inhaled, may convey the disease into the system. That flies which have found access to the excrement of typhoid fever patients may carry the infecting organism to food and so produce typhoid was proved in the Spanish-American and the Boer wars. The danger of typhoid in armies is always imminent; soldiers will drink polluted water, not caring to wait till it is boiled; the ground becomes saturated with discharges; flies and dust abound, and many of the men will not keep clean. "Typhoid fever in our camps," says Sternberg, "has been to a large extent due to the neglect of well-known sanitary measures." This has been the experience in nearly all wars.

Experiments have shown that infected clothing, surface soil, fæces and urine retain active bacilli for many days and there is reason to believe that typhoid is sometimes spread through infected hands, clinical thermometers, water-closets, clothing, etc. The New York department of health, which insists upon the importance of disinfecting the urine as well as the fæces of typhoid patients, states that "it is probable that in 50 per cent of the cases the typhoid bacilli are present in the urine at some stage of the disease," and recommends keeping the urinal or bed-pan partly filled with a 1 to 20 solution of carbolic acid.

Two important means in the diagnosis of typhoid have come into use within the last few years; namely, Erlich's test or the diazo-reaction and the Widal test. The first, which has the advantage of being more readily applied, is as follows: "Equal parts of the suspected urine and a solution (saturated solution of sulphanilic acid in 5 per cent hydrochloric acid 40 parts; 0.5 per cent solution of sodium nitrite 1 part) are mixed and well shaken. On the addition of a few drops of ammonia a brilliant rose-pink color should appear, if the case be one of typhoid fever. The 12-hour sediment is also characteristic, consisting of a dirty gray lower layer and a narrower dark olive-green upper layer." The reports of army surgeons in the great European War (1914–18) show that the affection known as "para-typhoid" is more common than typhoid. It has most of the symptoms of typhoid but less pronounced and has been responsible for deaths, which have been imputed to other causes. It is believed that the bacilli responsible are a union of the Eberth and Colon bacilli as shown by the Widal reaction. A mixed serum has been used hypodermically with success against both.

Prophylaxis.—"An epidemic is like a conflagration,— it is more easily suppressed at the beginning." "An ounce of prevention is worth a pound of cure." These are two sayings quite applicable to typhoid fever. The Ithaca epidemic might have been prevented by keeping the water supply pure; but once started, "all the science of the 20th century could not save all the lives." Purity of water and cleanliness of foods, proper cooking, the thorough removal and destruction of refuse, the use of septic tanks for sewage, the getting rid of flies and other hygienic measures are the means for preventing the origin and spread of typhoid; but these measures must be persistent, not spasmodic. The term summer typhoid is frequently applied to typhoid fever appearing in cities in the fall, but originating in country summer resorts — classed, it may be, as healthful.

It is now well known that from 2 to 10 per cent of all cases of typhoid become "carriers" of the disease, some "temporary" for about three months, others "chronic" for an indefinite period, continuously or intermittently for years it may be.

Such carriers as well as walking cases of typhoid are frequent sources of infection. The bacilli collect in the gall bladder, multiply and discharge into the intestines and find their way into the urine. The germs in the undisinfected excreta of these people are carried by flies or soiled hands to food. Even persons who have never had typhoid may become carriers. "Ty-

phoid Mary» was such a carrier, acting as cook in various families and in a hospital she was responsible for 57 cases of typhoid and three deaths. Boards of health now issue directions to «carriers.»

The various efforts that have been made by the use of internal medicines such as salvarsan and unotropin, to rid the body of a carrier of the lurking germs have only been partially successful.

Anti-typhoid serums and bacterins are used hypodermically with excellent results as immunizing agents — and as a cure. The prevention of typhoid by such means in armies is a triumph.

In 1901 Parkes and Rideal reported that after detailed experiments made to determine what substances could be added to drinking-water containing typhoid or other infecting micro-organisms to make it innocuous, they had decided upon acid sodium phosphate or sodium bisulphate, in compressed tablets of five grains each, to be used three to a pint of water 15 minutes before drinking, and when not in use to be kept in a closed receptacle, as a metallic box. They believe that the substance will be efficacious unless the water is very badly polluted. The statement has been made repeatedly in newspapers that lemon-juice destroys the typhoid bacillus, and therefore should be added to suspected drinking-water. W. H. Park, the bacteriologist, shows on the contrary that while the acid kills the micro-organisms it requires too much acid and too much time for the chemical action to take place to render lemon-juice a practical agent for their destruction.

Symptoms and Course of the Disease.— The duration is usually from three to four weeks in adults in cases of recovery, though the patient may be sick many days beyond the 28th, owing to diarrhœa, loss of muscular tone, flabby heart, etc. Death may occur in the first and even the fourth week, or later, but usually takes place in the second or third week. It may result from a peritonitis set up by perforation of an ulcerated spot, from intestinal hemorrhage, even after all the leading symptoms are gone, from diarrhœa, pneumonia, nephritis, embolism, thrombosis, etc. The period of incubation, which is not definitely known, is variously stated to be from 7 to 21 days. It is difficult to determine the exact time of exposure to the poison, and the onset of the attack is usually insidious.

First Week.— The disease begins with more or less fever, lassitude and aching «in the bones,» and sometimes a chill, more often a chilly feeling, especially when the hands are put into cold water or the person is exposed to cold air. Headache, pains in the back and limbs, alternations of chilliness and heat, and sometimes vomiting, nosebleed, diarrhœa and tenderness of the abdomen supervene. The pulse rarely exceeds 85 or 90; the tongue is moist, but covered with a thin coating; the fever gradually increases, remission occurring in the morning. Toward the end of the first week the tongue becomes dry, delirium is likely to occur, weakness is marked, consciousness is numbed and diarrhœa may increase. Toward the end of this week a rash sometimes appears, consisting of small pink spots, most abundant on the abdomen and chest, then on the back and rarely on the face and extremities. The spots continue to come out as long as the fever continues, do not coalesce, disappear under pressure, and do not become hemorrhagic.

Second Week.— The tongue is very dry; if there has been diarrhœa it increases, or may appear for the first time, and is attended by gurgling, the discharges having a peculiar «pea-soup» appearance. There is more or less tenderness over the ileo-cæcal region, due to the inflammation of Peyer's patches, and some tumidity of the abdomen. Delirium increases; temperature rises at night to 102°, 104°, 105° F., or more with sharp declines in the morning (steeple-like rises, as shown on temperature chart); the pulse is frequent — 100 to 120.

Third Week.— Gradually the patient passes into the third week, and symptoms slowly abate; or he grows worse; then the tongue cracks and bleeds; sordes appear on the lips, teeth and tongue; he has low muttering delirium; tympanitis is considerable; fever continues. He may recover even now, but there is the possible danger of hemorrhage, perforation or a serious depression of the vital forces, at any stage of the disease, but chiefly in the second and third weeks. As recovery sets in the greatest care is necessary that the patient may not overeat nor exert himself unduly, lest a relapse should occur or a serious complication be induced.

Treatment.— The treatment consists of rest in bed from the outset, diet, hydrotherapy and medicines. The food through most of the sickness should be largely liquid — milk, peptonoids, etc., and predigested material, but always adapted to the patient's powers of digestion. If curds or undigested food be seen in the stools, all food should be suspended for a considerable time, or given of another kind and in small quantity every three or four hours. Later, bread and milk, milk pudding, with rice or tapioca, eggs lightly boiled, poached or shirred and cocoa may be given. The patient may drink freely of water at any time, and may have fruit-juices. When the temperature has been normal for several days he may have fish, chicken, broths, soups and may carefully and gradually resume ordinary food. Sponging with tepid or cold water, vinegar and water, or alcohol and water, and the use of wet packs — as frequently as they can be used with apparently good results are often more serviceable than drugs. Yet medicinal measures are often necessary. Coaltar derivatives should never be used except to lower the temperature, and then very carefully. Eliminatives, as calomel and intestinal antiseptics, as salol, are useful. Acetozone, or benzolyl-acetyl-peroxide, is now used internally as a germicide with benefit in many cases. Stimulants should only be used when there are signs of heart-failure and then in moderate quantity — brandy, whisky, champagne, ether and camphor. Opium, carefully used in excessive diarrhœa or in peritonitis; ice internally, and applied to the abdomen in intestinal hemorrhage; ergotine hypodermically; bromide of sodium, etc., producing necessary quiet or sleep, are all of value; but the disease cannot be shortened in its course to any extent, though its severity may be modified. Skilful nursing, therefore, is necessary. The prevention of bed-sores and the keeping the mouth

clean add much to the patient's comfort and help him to recover.

Typhoid fever in children is more common than was at one time believed. It is the "remittent" fever of childhood, the "infantile hectic" fever, etc., and seldom occurs under one year of age. It does not conform closely to the type of typhoid in adults and differs as to distinct stages and well-defined temperature changes. It runs its course in from 10 to 20 days, and is characterized by gastro-intestinal catarrh, fever, prostration, wasting, nervous symptoms and scanty isolated eruption. See PATHOLOGY.

TYPHON, tī'fŏn, in Greek mythology, a giant, the son of Tartarus and Gæa. He had 100 heads shaped like those of a serpent and with devouring flames darting from the many mouths and eyes. Typhon, as soon as born, made war on heaven to avenge the death of his brother giants, compelling the gods to fly for safety; Jupiter, however, regaining courage, threw off the resemblance of a ram which he had assumed, and, hurling his thunderbolts at the audacious invader, flung him to earth wounded and writhing, when, to prevent his recovery, he cast Mount Etna at his head and buried the rest of his body beneath the earth. Through this vast mountain, however, the imprisoned giant still belches forth his fire and smoke and howls his discordant thunder. Consult Longfellow's poem 'Enceladus,' and Meyer, M., 'Die Giganten und Titanen' (1887).

TYPHOON, name given by navigators to those tremendous rotatory storms of wind or hurricanes that visit the coast of Tonquin and China as far north as Ningpo and the southeastern coast of Japan. Typhoons are the cyclones of the Eastern Asiatic Coast. They occur from May to November but are most frequent during July, August and September. They resemble the great hurricanes of the West Indies in their general characteristics, but with the main features more strongly marked. There is a depression of the barometer, over a space more or less circular, accompanying the typhoon, but it is generally more contracted in area, and deeper and more abrupt than in European or American storms. It is not uncommon for the barometer, at the centre of the depression, to read 28.3 inches, and on rarer occasions to fall even as low as 27 inches, and the changes of pressure are very rapid, frequently two or three inches in an hour. It is this enormous difference of atmospheric pressure between neighboring places, and the consequent rapidity of the fluctuation, which gives the typhoon its terribly destructive energy — the law regulating the strength of the wind being, that it is proportioned to the difference of pressure between the place from which it comes and the place toward which it blows. The low pressure in the centre is confined to a very limited space, and since all round this space the pressure is greater, it follows that the level of the sea there will be higher. Hence a high wave frequently accompanies a typhoon, advancing inland, carrying with it ruin and dismay, and sometimes bearing ships far over the level fields, where they are left stranded. Typhoons have their origin in the ocean east of China, especially about Formosa, Luzon and the islands immediately south. They thence proceed, in four cases out of five, from east northeast toward west southwest, rarely from east southeast to west northwest, in other words, their course is generally along the coast of China. The whole body of the typhoon advances at the rate of 12 miles or more an hour; within the body thus traveling the winds often blow 80 to 100 miles an hour, whirling round the centre of atmospheric depression in a direction contrary to the motion of the hands of a watch, as do all the storms in the northern hemisphere. They thus rotate in the directions south, east, north, west, and travel along the coast, so that the coast feels the north side of the typhoon, while at a distance from the coast the south side alone is experienced. The rotation, however, is in circles not returning on themselves, nor opening outward by their centrifugal motion, but tending to blow somewhat inward upon the centre of lowest pressure. The intensity of the typhoon is aggravated by the large quantity of heat disengaged in the condensation of the vapor of the atmosphere into the deluges of rain which fall during the storm — 10 to 12 inches of rain frequently falling in one day. The meteorological offices at Manila, Hongkong and Tokio publish special studies and charts of typhoons from time to time, while the general paths with special explanations are published in the monthly pilot charts of the Pacific issued by the United States Hydrographic Office. Consult Algué, José, 'The Cyclones of the Far East' (2d ed., Manila 1904); and Doberck, W., 'Law of Storms in the Eastern Seas' (4th ed., Hongkong 1898).

TYPHUS FEVER, a highly contagious eruptive fever, one of the exanthemata (q.v.), formerly known as putrid, ship, jail or camp fever, and by other names. The disease is very rare in the United States, and when it appears it is usually in the line of immigrant travel. But owing to the very strict quarantine regulations of the American and Canadian governments it is seldom imported, or if introduced is stamped out by thorough isolation and disinfection. A constant vigilance is exerted to prevent the importation of old rags, which are seldom free from infection. The disease is also rare in the great centres of population in Europe and elsewhere, but it is epidemic in certain towns of the Old World and in some parts of Latin America where sanitation is of a most primitive kind. It is a filth-disease, therefore a disgraceful disease, and its occurrence is favored by overcrowding, bad ventilation, poor food, etc., and is especially more likely in winter. The body louse is the carrier of the disease. Though resembling typhoid fever in some respects, it is easily recognized, quarantined, disinfected and controlled. It is caused by the bacillus typhi exanthematici, discovered by Dr. Harry Plotz in 1915. There are no characteristic lesions, except that the blood contains but little fibrin and is darker than normal, and the spleen and liver are engorged and softened. Sometimes the stomach and lungs are also softened. The real cause of death is not usually acertained. The mortality of typhus fever is not much more than that of typhoid fever when there is good ventilation and strict attention to other hygienic measures, but in overcrowded and badly ventilated prisons, etc., it is very great.

The average duration of typhus (14 to 21 days) is less than that of typhoid fever. The incubation period varies from one to two weeks. The fever begins much in the same way as typhoid, with lassitude, aching in the limbs, headache, chills or chilliness, rapidly rising temperature and dark flushing of the skin. The eyes are moderately congested; there is little disposition to diarrhœa; the abdomen is not swollen or tender; and the patient is not likely to vomit, or to have nosebleed. The tongue soon becomes dry and dark, and sordes form; the pulse is frequent; as the fever reaches its height the breath and perspiration have a peculiar musty odor, and the patient passes from a state of delirium into a nearly comatose condition. Toward the end of the first week (usually the fourth or fifth day) an eruption appears on the sides of the abdomen, in the axillæ and about the wrists. For the next two days it continues to appear over the rest of the skin, except that of the face, and is most abundant on the trunk. After the third day it ceases to come out. At first the spots disappear under pressure, but after a day or two they fade out like black-and-blue spots, and in another day or two a small petechial hemorrhage appears in many of them. At its height the rash has a dull red color which Sir William Jenner compared to the juice of a ripe mulberry. When the spots coalesce and spread over a large space much danger is indicated. Treatment consists in combating the evils which give rise to the disease. The patient should be kept in a well-ventilated room with windows open even in winter; but he must also have plenty of bed-clothes, and there must be a fire in the room. Keep the room and patient thoroughly clean, and see that he has an abundance of good and easily digested food. Stimulants and other medicines will be seldom needed, yet a physician must not be dispensed with, since complications such as erysipelas and abscesses may occur. Plotz used a vaccine with considerable success in Serbia during the great epidemic there in 1915. Consult Vaughan, C. C., 'History and Epidemiology of Typhus Fever' (*Journal of the American Medical Association*, Chicago, 29 May 1915).

TYPOGRAPHICAL UNION, International, a society of typesetters, compositors and linotypers banded together for mutual protection, for the regulation of wages, fixing the number of apprentices allowed to each establishment, the length of time each apprentice must serve in order to become a master workman, and for extending general aid to the members of such association. The international or supreme body is composed of delegates from subordinate unions in the United States and Canada. The management of the internal affairs of each union is left almost entirely to the subordinate divisions. Thus each local union may regulate the number of apprentices, the scale of wages for composition, time work, etc. Whenever a member of one local union comes within the jurisdiction of another local body, he at once is subject to the by-laws of the latter. Traveling cards are granted to members, but these cards must be deposited with the local union within the jurisdiction of which its holder proposes to remain for a given length of time, and dues must be paid into the local union with which the card is deposited. It was founded in 1852 as the National Typographical Union, taking the name International in 1869. In 1882 there were 95 local organizations and a membership exceeding 10,000. In 1916 there were 754 local unions and 60,231 individual members. There are hundreds of local unions in the United States, that of New York being the largest, having a membership of several thousand — followed by Chicago, Philadelphia, Boston, Saint Louis and other large cities of the country. The International Union meets once every year, at different places in the United States and Canada. The permanent headquarters are at Indianapolis, where a large school of instruction is maintained. A home for disabled printers and tuberculars is also maintained at Colorado Springs.

TYPOGRAPHY. See PRINTING.

TYPOTHETÆ, a name given to a trade guild consisting of persons connected with the printing trades, both workmen and employers. In the year 1465 the Emperor Frederick III of Germany "permitted printers to wear gold and silver, and both the typographi and typothetæ were honored by him with the privilege of bearing coat-of-arms, and wearing armor. The shield of the typothetæ bore an eagle with extended claws, and the open helmet was surmounted by a crown." The first use of the name in the United States was in 1863, when P. C. Baker of New York proposed the name for a society of employing printers in that city. The name was adopted, but the society did not survive long. In 1883 the Typothetæ of the City of New York was resuscitated. From that city similar organizations spread all over the country, and in 1887 the United Typothetæ of America was formed. Later the Printers Boards of Trade, mostly known as Franklin Clubs, were taken into the organization, and the title now is United Typothetæ and Franklin Clubs of America. There are local Typothetæ in most of the large cities of the United States and Canada. The organization has ceased fighting actually against unionism, and confines its activities largely to trade education and improvement of conditions.

TYR, tir, in Norse mythology, the son of Odin, and the god of war and of renown. According to the Edda, he had but one hand. When the Asa-gods persuaded the wolf Fenrir to allow himself to be bound with the Gleipnir, Tyr put his right hand in the wolf's mouth, as a pledge that he would be loosened; and when the gods refused to release him, the wolf bit off Tyr's hand to the wrist, which was called in consequence, Ulflithr, or the Wolf's Joint. In the twilight battle of the gods, he meets his death at the same time with his enemy, the monster dog Garmr.

TYRANT, a word derived from the Greek *turannos*, which signified an absolute ruler. The word did not have originally the bad signification which we now attach to it; but as it is a rule which admits of very few exceptions, that the possessor of uncontrolled power, whether individual, corporation, or multitude, will abuse it, tyrant came at length to signify an abuser of power, particularly of the chief power in the state. Consult Plasz, 'Die Tyrannis bei den Griechen' (Berlin 1887), and Schömann-

Lipsius, 'Griechische Alterthümer' (4th ed., ib. 1897).

TYRCONNEL, tĕr-kŏn'ĕl, **Richard Talbot**, EARL OF, viceroy of Ireland: b. about 1630; d. Limerick, 14 Aug. 1691. He was the youngest son of Sir William Talbot, a prominent figure in politics under James I. At Drogheda he was with the forces that withstood Cromwell and one of the few that escaped the massacre there. On the accession of James II Talbot was at once made Earl of Tyrconnel and placed in command of the troops in Ireland, where he strove to secure the king's independence of Parliament by favoring Roman Catholics in the army and in official preferments, at the expense of Protestants, many of whom he summarily dismissed. In 1687 he was made lord deputy of Ireland, an appointment that added dismay to the consternation which he had already spread among the English Protestants there, many of whom quitted the country, a great part of which was given over to lawlessness, commercial decay and general wretchedness. In 1689, when James reached Ireland after his flight from England, he created the earl Duke of Tyrconnel. After the battle of the Boyne (1690), in which he fought, the duke retired to France, but in 1691 returned to Ireland and further endeavored to serve the cause of James, which, however, was soon hopelessly lost.

TYRE (mod. Arab. *Sûr*), the most famous city of ancient Phœnicia, in lat. 33° 12′ N., named probably from the double rock on which it was first founded. It was doubted among the ancients themselves whether Tyre or Sidon was the older, and the question is not settled; though it seems certain that Tyre had long existed independently when Sidon, defeated by Ascalon, transferred herself almost bodily to Tyre. There were two towns of Tyre closely connected in historical times — one on the continent, the other on the island opposite, together comprising, according to Pliny, about 19 Roman miles. The more important of the two was the continental town, Palæ Tyrus; while the island-town served more or less for storehouses, manufactories, arsenals and the like. The entire city was in a fertile region; and its magnificent combination of land and sea scenery formed the theme of many an ancient poet and seer. Nothing but myths have come down to us respecting Tyre in its earlier period. Its history dawns on us with Abibal, predecessor of the biblical Hiram, under whose rule (B.C. 980–947) Tyre attained its full glory and renown. An alliance with Solomon was entered into; trading expeditions were undertaken jointly by the Israelites and the Phœnicians; and Solomon is supposed even to have married Hiram's daughter. During Hiram's reign, Tyre was much enlarged and embellished; and its two roadstead and harbors, among the wonders of the ancient world, date probably from the same period. He was followed, according to ancient writers, by Balæastartus; after him reigned, for brief periods, his four sons, by the murder of the last of whom the throne became hereditary in the house of Ithobaal, the Ethbaal of Scripture, whose daughter was married to King Ahab. Tyre then appears to have gained the supremacy over Sidon and also spread her colonies far and wide. Shortly after the death of this king, Carthage was refounded by Elissa (Dido), about 813 B.C., in consequence of a popular demonstration which deprived her of the throne in favor of Pygmalion. This "new city" gradually diminished the importance of the old one; at least Tyre seems to have been weakened to such an extent by the emigration of its best elements that it disappears from history until the three great powers, Chaldæa, Assyria and Egypt by turns endeavored to make themselves masters of the Tyro-Phœnician Coast, with its east and west trade. Shalmaneser, king of Assyria, reduced Tyre after a long siege; and the whole of Phœnicia, the most important places of which had already thrown off their allegiance to Tyre, was rendered tributary to Assyria. During the Chaldæo-Egyptian struggle, Tyre, again at the head of the country, sided with Egypt and was conquered by the Chaldæans. Once more the Phœnicians attempted to throw off the foreign yoke, and Nebuchadnezzar marched against them at the head of his armies. Having taken Jerusalem in B.C. 587, he reduced the whole sea-coast, except Tyre, which stood 12 years' siege by water and by land, ending not in subjection, but only in an apparent submission, leaving the native sovereigns on their thrones, and their wealth and power untouched. In B.C. 538 Cyrus became master of Phœnicia, which at that time again was under Babylonian supremacy, and the hegemony was bestowed on Sidon. For a long time Phœnicia prospered under wise Persian rulers; but when Xerxes in his Greek wars, had completely destroyed the Phœnician fleet, and exhausted nearly all her resources, the exasperated inhabitants rose once more, but only to be utterly crushed. Sidon, at the head of the Revolution, was fired by its own inhabitants and again Tyre resumed the lead in 350 B.C. Having refused to pay allegiance to Alexander the Great after the battle of Issus, it was besieged by him in B.C. 332 and fell after seven months' hard resistance. Alexander replaced the old inhabitants by new colonists, chiefly Carians; and though the city had been almost destroyed, it rose again after a brief period to wealth and power, and in B.C. 315 was able to hold out 18 months against Antigonus. Under the Romans, Cleopatra received Tyre as a present from Antony; but the last trace of its independent existence was taken from it by Augustus. A Christian community had then been founded there. The trade and manufacture of Tyre, aided by its exceptionally favorable naval position, gave it, even under Roman dominion, a high place among its sister cities; and once again, in A.D. 193, it even took active part in the contest between Septimius Severus and Pescennius Niger, which, resulting in the success of Severus, brought back to it some of its ancient distinction. In Saint Jerome's time it was again the most beautiful city of Phœnicia, and one of the most prosperous cities of the whole East. In the 7th century it came under the dominion of the Saracens and so remained until taken by the Crusaders and in 1192 became the northern boundary of Christian territory in Palestine. It continued to flourish — still chiefly through its renowned manufacture of purple — until 1516, when the conquest of Selim I, together with the newly-discovered route to Asia by the Cape of Good Hope, put an end to its

wealth and commerce and almost to its existence. Although there has been a slight improvement in its prospects of late, the magnificent city of old still presents a scene of desolation and wretchedness. About 6,500 inhabitants now dwell in Sûr, among the ruins of its ancient glory, finding scanty livelihood in exports of tobacco, cotton, wool and wood. Consult Bérard, Victor, 'Les Phéniciens et l'odyssée' (Paris 1903).

TYRE, Bank of. The city of Tyre was ancient in the time of Alexander the Great. Directly or otherwise, its trade extended to all parts of the known world and embraced every commodity included in commerce. Its ships and caravans fetched tin from Britain, ivory and gold from Africa, spices and frankincense from India. For return cargoes they carried those woolens, colored by precious dyes, which constituted the basis of all its other commerce, the "bales of (purple) blue and broidered work and chests of rich apparel" mentioned in Ezekiel, xxii, et seq., a monopoly so odious to the Persians that the wife of Darius refused even to touch a piece of Tyrian woolens (Quintus Curtius, ii, 17). The enormous wealth thus created naturally led to the establishment of a bank, which after many vicissitudes was still found existing, when in A.D. 1124 Baldwin, brother of Godfrey de Bouillon, led his crusaders from the capture of Tyre, to that of Roha or Edessa, near the fords of the Euphrates. It was here that were situated the famous woolen and fulling mills and dye-works of the Tyrians. The advantages of the place were a fall of water for power, the adjacent alum deposits of Roha for mordants, the clays for fulling and the river for transport. The dye-stuffs being light were easily brought from the seacoast, where Godfrey secured the convenient shipping port of Joppa, which he erected into a countship.

Edessa was no new manufacturing town. Under its ancient name of Oorfa or Urfa it had been one almost as long as Tyre had been a trading emporium. The two places had probably been connected ever since they were founded by the Kheta, for its name of Oorfa was merely a replica of that Mongolian Oorga which down to the present day is celebrated for its woolen manufactures and beautiful but secretly applied dyes; while as to the elusive Carchemish, where the Kheta were overthrown by Sargon, it was situated at or near the fords of the more recently named Edessa.

Following the example of his brother Godfrey, Baldwin, for himself, now erected Edessa into a countship and stretched its territorial boundaries across the Euphrates, with the view to enlarge its scope of taxation, as well as its facilities for trade. He also rehabilitated the ancient Bank of Tyre and invited his crusading brethren, the Rhodians and Venetians, to make avail of its advantages as a place of security for the treasures which they were daily plundering from the surprised and defeated Greeks and Moslems. These became its principal depositors. Alluding to the crusading knights for description, Hallam says in his very first chapter: "Men resorted to Palestine, as in modern times they have done to the Colonies: in order to redeem their time, or repair their fortune. Thus Gui de Lusignan, after flying from France for murder, was ultimately raised to the throne of Jerusalem. . . . It was here in 1099, when their triumph was consummated, that it was stained with the most atrocious massacre; not limited to the hour of resistance, but renewed deliberately, after that penitential procession to the Sepulchre, which might have calmed their ferocious dispositions."

The avarice of the Knights of Rhodes was nowhere exhibited more glaringly than in their connection with the Bank of Tyre. This depository was first pounced upon by the Venetians, who after taking possession of its treasure and issuing in its stead parchment bank notes, signed by the doge Dominico Michieli, petitioned King Godfrey at Jerusalem to continue them (the Venetians) in the bank's "mercantile privileges." Instead of making this concession Godfrey conferred the "privileges" upon his brother Baldwin. Among the coveted advantages of the bank was the monopoly of the wool trade which now became the spoil of the French knight.

After Baldwin had set up his mills and dyeing works at Edessa, after he had employed the most cruel means to force from the natives the secrets of their trade, after Godfrey had arranged an organized resumption of the commerce of Tyre, reviewed its ancient bank and secured and improved an additional sea-port at Joppa, their fellow-crusader, Rohemond, a son of Robert Guiscard, led several shiploads of lazzaroni from Naples, to ravage the East, steal from his allies the stolen secrets of Edessa, and carry them to Italy, there to continue the once famous woolens trade of Tyre in the Bay of Taranto.

From that moment the Bank of Tyre declined; plunder still continued to come in and some measure of profits was gleaned from the melting of bullion, exchanges of coins, charges for the safekeeping of treasure, etc., but these items were not sufficient to support such a bank and cover the risk it ran from fire, robbery or successful fraud. The commercial community of Tyre was gone; its shipping, its trade, its connections were gone; more than all, its great woolens trade was gone; and with little prospect of their revival. Yet a forlorn hope of improvement seems to have kept it alive, or nominally alive, until the year 1145, when Edessa was besieged by a native army commanded by the brave Zenghi, or Sangiar, one of the Atabek sultans, who, after a fierce struggle of 25 days, finally made a practicable breach in its formidable walls and entered the city sword in hand. His triumph, however, was marked by his death, for here, as Gibbon regrettingly relates, fell "the last hero of his race." Although Tyre remained in the hands of the triumphant Latins, its woolens trade was lost; its commercial importance annihilated; and its bank expired and was forgotten. For the history of other ancient banks see BARCELONA, BANK OF; BYZANTIUM, BANK OF; FUGGERS, BANK OF THE; GENOA, BANK OF; MEDICI, BANKS OF THE; VENICE, BANK OF.

TYRNAU, tĭr'now, or **TIRNAU**, a town of Hungary, about 30 miles northeast of Presburg, on the Waaj Valley Railroad. Its interest was lost when the university was removed to Pesth (1635–1754). Cloth, linen, vinegar, sugar and wine are manufactured. It was for-

merly the residence of the Hungarian primates. Pop. 14,759.

TYROL, tĭr'ŏl (Ger. tē-rōl'), or **TIROL,** Austria, a crownland and principality, situated in the western part of the empire, 11,224 square miles in area, and bounded on the north by Bavaria, on the east by the crownlands of Salzburg and Carinthia, on the south by Italy and on the west by Italy, Switzerland and Vorarlberg. With the latter crownland it forms an administrative district. Its area, exclusive of Vorarlberg, is 10,300 square miles. Almost the whole area is included in the Eastern Alps, which are here almost as high and quite as complex, wild and romantic as the Swiss Alps, including large glaciers, gorges and mountain torrents. The highest point is the Ortler Spitze on the western boundary; altitude, 12,802 feet. The chief rivers are the Inn in the north, flowing into the Danube, and the Adige in the south, flowing to the Adriatic. But little of the soil is suitable for agriculture though considerable quantities of grapes and fruits are grown. Cattle, sheep and goats are raised in large numbers. Iron, zinc, copper and lignite are mined to some extent. The principal industries are cotton spinning and weaving. The chief exports are cattle, cheese, lard, wine and fruit. Of the inhabitants 55 per cent are German and 44 per cent Italians; nearly all are Roman Catholics. The capital is Innsbruck. Tyrol was anciently the eastern portion of Rhætia. It came under the House of Hapsburg in 1359 through Margaret, the heiress of the last counts. In 1805 it was ceded to Bavaria, but restored to Austria in 1814. Pop., exclusive of Vorarlberg, 852,712.

TYRONE, tī-rōn', **Hugh O'Neill,** 2d EARL OF, Irish chieftain and soldier: b. about 1550; d. Rome, 1616. He was the grandson of the 1st earl and son of Baron of Dugannon. His early life was spent in England. After the murder of his brother in 1562 he returned to Ireland, succeeding to the barony. He was called "The O'Neill," and was the leader of the Irish insurrection against Elizabeth and English occupation. Both Connacht and Leinster soon joined the standard of the Ulstermen and were met by an English army under the Earl of Essex and engaged in a war for supremacy. For some years Tyrone baffled the English army, but was overcome by Lord Mountjoy in 1603, in spite of the aid of Spain, and compelled to surrender. He was pardoned later and reinstated in his earldom. In 1607, being suspected of further intrigue, he fled to Brussels, and later to Rome, where he passed the remainder of his life living on a small stipend furnished jointly by the Pope and the king of Spain. Consult Meehan, 'Fate and Fortunes of Tyrone and Tyrconnel'; Gainsforde, 'True Exemplary and Remarkable History of Hugh, Earl of Tyrone' (1619); Bagwell, 'Ireland Under the Tudors'; Mitchel, John, 'The Life and Times of Aodh O'Neill' (New York 1868); McRory, S., 'Beatha Aoidh Ui Neill' (Dublin 1906).

TYRONE, Pa., borough, Blair County, on a tributary of the Juniata River, and on branches of the Pennsylvania Railroad, about 15 miles north by west of Altoona and 90 miles west by north of Pittsburgh. It was settled in 1840 and incorporated as a borough in 1857. It is in an agricultural region in which there are deposits of iron and nearby considerable timber. The chief manufacturing establishments are railroad shops, paper mill, iron works, lime kiln, lumber mills, shoe factory, chemical works and candy works. The educational institutions are a high school established in 1878, public and parish schools and a school library. There are several churches. The banks have a combined capital of over $400,000. The government is vested in a burgess and a council of 14 members who hold office for two years. Pop. 7,176.

TYROTOXICON, or **CHEESE POISON,** a ptomaine or poisonous principle produced in cheese and in milk by putrefaction, and the usual cause of the poisonous symptoms sometimes following the eating of ice-cream and other milk or cream preparations. The name was first bestowed by Kuhn of Leipzig, in 1824 on the poisonous principle in putrefied cheese, and by Vaughan of Michigan in 1885 on the alkaloid that he obtained by evaporating an acidulated aqueous and etherized extract of the poisoned cheese. Tyrotoxicon poisoning is accompanied by intense pain, nausea, diarrhœa, throat constriction and weakening of the heart's action. Prompt treatment should be rendered in the form of emetics, or saline purgatives, and tonics to stimulate the heart's action. See PTOMAINES.

TYRRELL, George, British Catholic theologian: b. Dublin, 1861; d. London, 1909. He was educated at Trinity College, entered the Catholic Church (1880), became a Jesuit priest (1891) and was appointed instructor in philosophy at Saint Mary's College, England (1896). He was expelled from the Jesuit order (1906) for doctrinal reasons and was excommunicated a few years later for criticizing the Pope's encyclical on modernism. In 1908 he was attacked by Cardinal Mercier and replied in a volume called 'Mediævalism.' Among his publications was 'Christianity at the Cross Roads' (1909). Consult Egerton, H., 'Father Tyrrell's Modernism' (London 1909); Petre, M. D., 'Autobiography and Life of George Tyrrell' (2 vols., London 1912).

TYRRELL, James Williams, Canadian civil engineer: b. Weston, Ontario, 10 May 1863. He took his degree as civil engineer at Toronto University in 1889 but before this date was topographer of the Geological Survey of Canada. In 1885 he joined the Hudsons Bay expedition and was employed in that work on the steamer *Alert* until 1886. He practised his profession in Hamilton, Ontario (1889–93), accompanied his brother as Eskimo interpreter on an expedition from Lake Athabasca through the Barren Lands to Chesterfield Inlet (1893), and was engaged by the government to survey the country between Great Slave Lake and Hudsons Bay (1900). He was elected president of the Ontario Land Surveyors' Association in 1905, gazetted lieutenant of the Corps of Guides (1907) and promoted to be captain (1910). He has published books on his travels.

TYRRELL, Joseph Burr, Canadian geologist: b. Weston, Ontario, 1 Nov. 1858. He was graduated at Toronto University in 1880 and at Victoria University (B.Sc.) in 1889. He was appointed to the Canadian Geological Survey staff in 1881. He accompanied the Daw-

son Survey of the Rocky Mountains (1883) and began the exploration of the country north of Calgary between the Bow and Saskatchewan rivers (1884–87). He continued his explorations in the Hudsons Bay country for years and in 1895 he retired after being promoted to a captaincy in the Governor-General's Foot Guard. In 1908 he offered a prize for the best collection of minerals and was elected president of the Canadian Institute (1910, 1911). He is the author of numerous scientific papers.

TYRRELL, tĭr'ĕl, **Robert Yelverton,** Irish classical scholar: b. Ballingarry, Tipperary, 21 Jan. 1844; d. 1914. He was graduated at Trinity College, Dublin, where he became a Fellow in 1868, professor of Latin in 1871, and regius professor of Greek in 1880. In 1898 he became professor of ancient history and after 1904 served as registrar. He is the author of 'Bacchæ of Euripides' (1891); 'Correspondence of Cicero' (1879–1900); 'Acharnians of Aristophanes in English Verse' (1883); 'Miles Gloriosus of Plautus' (2d ed., 1886); 'Sophocles' (1897); an 'Anthology of Latin Poetry' (1893); 'A Second Anthology' (1901); 'Echoes of Kottabos' (1906), with Sir E. Sullivan; 'Essays in Greek Literature' (1909).

TYRRHENIAN (tĭ-rē'nĭ-ạn) **SEA,** that portion of the Mediterranean Sea which is enclosed between Sardinia, Sicily and the Italian peninsula.

TYRTÆUS, tẻr-tē'ŭs, Greek poet who flourished about 630 B.C. His birthplace is unknown. In the war between the Lacedæmonians and Messenians, the former applied to the Athenians for a general; and the latter, it is said, in derision, sent them Tyrtæus. The bard, however, so inspired the Spartans by his warlike songs, that they reduced the Messenians to subjection. He was accordingly treated with great respect, and received the rights of citizenship. Some fragments of his songs are extant. His poems are in Greek elegiac metre and in the time of the Hanoverian monarchy were translated into English and disseminated throughout the army for the purpose of fostering the warlike ardor of the soldiers. Consult Bergk, 'Poetæ Lyrici Græci' (Vol. II, 5th ed., Leipzig 1914).

TYSON, George Edgar, American Arctic explorer: b. New Jersey, 1829; d. 1906. He sailed with the *Polaris* American polar expedition (1871) and when wrecked in Smith Sound he assumed command of the party until they were rescued by the sealer *Tigress* (1873). They had drifted with the ice pack fully 1,800 miles in the 196 days in which Tyson had kept the party together under the most trying circumstances. Consult Blake's 'Arctic Experiences' (New York 1874).

TYSON, James, American pathologist: b. Philadelphia, 26 Oct. 1841. He was graduated at Harvard in 1860 and took his M.D. degree from the University of Pennsylvania in 1863. He was professor of pathology and morbid anatomy (1876–89), professor of the practice of medicine (1899–1910) and thereafter professor emeritus of the University of Pennsylvania. He was president of the College of Physicians of Philadelphia (1907–10) and is the author of numerous medical works of high reputation, dealing chiefly with the cell theory and diabetes.

TYTLER, tĭt'lẻr, **Patrick Fraser,** Scottish historical writer: b. Edinburgh, 30 Aug. 1791; d. Malvern, England, 24 Dec. 1849. He was educated at the University of Edinburgh, and in 1813 was admitted to the bar of Scotland. In 1837 he removed to London, where he devoted himself exclusively to historical writing and other literary pursuits. His 'History of Scotland,' begun in 1828, was completed in 1843, and was accepted as a standard work. He was also the author of 'Life of James Crichton of Cluny, commonly called the Admirable Crichton' (1819); 'Life and Writings of Sir Thomas Craig of Riccarton' (1823); 'Life of John Wicliff' (1826); 'Lives of Scottish Worthies' (1831–32); 'Historical View of the Progress of Discovery on the more Northern Coasts of America' (1832); 'Life of Sir Walter Raleigh' (1833); 'Life of King Henry VIII' (1837); 'England under the Reigns of Edward VI and Mary' (1839). He was granted a civil pension of £200 a year. Consult Burgon, J. W., 'Life of Patrick Fraser Tytler' (London 1859).

TYTLER, Sarah. See KEDDIE, HENRIETTA.

TYUYAMUNITE, tyū-yä-moon-īte, canary-yellow hydrous calcium-uranium vanadate, $CaO.2UO_3V_2O_5.8CH_2O$; occurs with carnotite, the most important of the radium minerals as mined at various localities in Utah.

TZANA, tsä'nä, **Lake.** See DEMBEA.

TZE-HSI, tzē-shē, empress dowager of China: b. Peking, 1835; d. 15 Nov. 1908. She was selected for the imperial harem when but 16 and by study and good fortune in her 26th year became the virtual ruler of China. She had an abundance of political wisdom which led to her selection of Li Hung Chang as her chief adviser. She was unable to prevent the Boxer Rebellion but its tragic results taught her a lesson and thereafter she encouraged the modernizing of China. It was largely through her influence that the country threw off the curse of opium. She was an ambitious woman but remarkably patriotic and her good deeds far surpassed the evil credited to her time. Consult Bland and Backhouse, 'China under the Empress Dowager' (Philadelphia 1910); Sergeant, P. W., 'The Great Empress Dowager' (New York 1911), etc.

TZETZE, tsĕt'sĕ, a musical instrument of the guitar kind, formed of a long carved neck attached to a gourd. It has one string usually made of the tough fibre of a palm tree. The tzetze is of Abyssinian origin.

TZETZES, tsĕt'sēz, **Johannes,** a Byzantine author of the 12th century. His 'Chiliades,' a very dull collection of 30,000 "political iambics," whose theme is stories drawn from Greek history and mythology, has been edited by Kiessling (Leipzig 1826); his 'Iliaca,' a résumé of Homer's 'Iliad' and kindred poems, by Bekker (1816). Commentaries on Homer, Hesiod, the 'Plutus' of Aristophanes and Lycophron's 'Alexandra' (ed. by Müller 1811), make up the remaining works of Tzetzes. Consult Krumbracker, K., 'Geschichte der byzantinischen Litteratur' (2d ed., Munich 1897) and Spelthahn, H., 'Studien zu den Chiliades des Johannes Tzetzes' (ib. 1904).

U

U the twenty-first letter and fifth vowel of the English alphabet. Its form in the Latin alphabet was V. In the Greek alphabet the character Υ represented a vowel sound different from that represented by the Latin V (the vowel *v* or *u*); probably this Greek letter stood for a sound like that of *u* in French, which in German is represented by *ü;* and the Greeks had no single character in their alphabet to represent the pure and simple vowel sound which *u* had in Latin and has in modern European languages except English and French: this vowel sound the Greeks represented by the digraph *ου* as it is usually represented in English by the digraph *oo;* and in French by *ou.* When a Greek word containing *υ* was to be translated into Latin the *υ* was represented by *y,* and the same is still done in English: Thoukydides (*θουκυδίδης*) and *τύχη* become Thucydides and Tyche. In the Latin alphabet the vowel *u* (*oo*) and the consonant *u* (or *w,* or *v*) were both represented by *V,* and not till late in the 16th century was the form *V* restricted to the consonant element. The sound of *u* (*oo,* not as named in English, *yu*) is produced by rounding the lips to the fullest extent consistent with a clear vowel sound and raising the back of the tongue higher than for any other rounded sound. This sound, short, is heard in *full,* and long in *fool;* and it is commonly represented in English by that digraph *oo;* in French it is represented by *ou,* but in the rest of the European alphabets by *u.* The fact that the primitive vowel sound *u* is expressed in English by *oo* is an indication that at one time the *o*-sound had a tendency to pass into the sound of *u*: thus *good, foode,* once were *gode, fode.* Besides the related sounds heard in *too* and *full, u* represents in English two other sounds, namely, the vowel sound heard in *tub, but,* and the diphthongal sound heard in *use, repute.* The sound of *u* in *but, tub* is especially common in English, and in unaccented syllables is represented also by other vowels, as *a, e* and *o;* examples *every, common, fashion,* which might be written *evury, commun, fashun. U* is consonantal after *g* and in some other places. It is silent in such words as *guard, build,* etc. *Gu* in French and in English words derived from the French is often derived from a Germanic *w.* The letter *u* in Chaucer's time was pronounced like French *u* in words derived from the French; and Sir John Cheke, writing 200 years after Chaucer, declares that in his day the *u* in *duke, lute, rebuke* was sounded "like the Greek upsilon," that is, like the French *u. U* stands for uranium in chemistry. See ALPHABET.

UARAYCU, ooâ-ri'koo, a tribe on the lower reaches of the Jura River in western Brazil. They are known for their peculiar customs, notably those for testing the fortitude of their children and for betrothal in childhood. They burn their dead and bury the ashes in their huts.

UARDA, by George Ebers. Two generations of German children, and a good many of their fellows in other lands, have had their first taste of Egyptian history and folklore through the medium of George Ebers' historical romance, 'Uarda' (1877) and its companion-piece, 'An Egyptian Princess.' Ebers, who was an Egyptologist of distinction, made a great point of the accuracy of his description of religious rites, science, warfare, dress, manners and customs; and yet, except to the young, 'Uarda' carries no illusion of ancient times because the characters themselves think and feel as moderns do. Uarda is a story of the time of Rameses II and the hero is Pentaur, the priest and epic poet.

UAUPÉS, wā-ō-pās', Colombia, a river rising in the eastern cordillera of the Colombian Andes, and flowing southeastward to the Rio Negro, which it joins in the northwestern corner of Brazil. Length about 700 miles. The lower course of the stream is navigable.

UBANGI, oo-bäng'gē, or **MOBANGI,** mō-bäng'gē, a river of Equatorial Africa, a tributary on the right bank of the Kongo, which it enters in lat. 0° 30′ S. It is the lower course of the Welle or Makua, which has its sources to the north of Lake Albert Nyanza. It is navigable, but there are difficult rapids at Zongo in 40° 20′ N. Throughout a large part of its course down to its confluence with the Kongo it forms the boundary between the Belgian Kongo and French Equatorial Africa. By means of the Kongo and the Ubangi it is possible to go from the coast of the Belgian Kongo almost to the Nile Valley. The basin of the river is very fertile and more thickly populated than most other parts of central Africa. The part of the river known as the Welle was discovered by Schweinfurth in 1870; other portions were successively explored by Junker (1880), Hanssens (1884), Grenfell (1886) and others, and about 1890 the several parts were identified as belonging to the Ubangi. Consult Wauters, A. J., 'Les bassins de l'Ubangi et de la Sanga' (Brussels 1902).

UBERTI, oo-bĕr'tē, **Bonifazio degli,** Italian poet: b. Pisa, about 1309; d. after 1368. He belonged to the noble family of Uberti, his grandfather having been a leader of the Florentine Ghibellines, and spent much of his time in exile. His 'Dittamondo,' an unfinished didactic poem in the style of the 'Divine Comedy' of Dante, placed him among the celebrated

writers of the Italian Renaissance. His lyrical poems received much later recognition. Consult 'Dittamondo' (Milan 1826); Pellizzari, 'Il Dittamondo e la Divina Commedia' (Pisa 1905); Renier, R., 'Le liriche edite e inedite di Fazio degli Uberti' (Florence 1883); Whitmore, 'Fazio degli Uberti as a Lyric Poet' (in *Romantic Review*, New York 1914).

UBIQUARIAN, ū-bĭ-kwā'rĭ-ạn, or **UBIQUITARIAN**, a believer in the doctrine that the body of Christ, in virtue of the hypostatic union of his divine and human natures, is everywhere — in Latin, *ubique*. The opinion was held by individual theologians in the 10th and succeeding centuries, foremost among them the renowned English schoolman William of Ockham in the 14th: Christ's body after his resurrection, he held, is ubiquitous. In the conference at Marburg of Luther and Melanchthon with Zwingli and Œcolampadius, Luther explained in this way the true, real, corporeal presence of Christ in the Eucharist; and in the authoritative Formula of Concord (1577) the doctrine of the ubiquity of Christ's humanity is expressly taught. But after Luther's death Melanchthon and other leaders repudiated Luther's doctrine of consubstantiation, while Brentius and Andreæ defended it as an article of Lutheran orthodoxy. See CONSUBSTANTIATION; TRANSUBSTANTIATION.

UCAYALE, oo-kī-ä'lä, or **UCAYALI**, Peru, a river flowing northward through the eastern part of the country, and joining in long. 73° 20′ W. the Amazon, of which it has sometimes been regarded as the true upper course. Its main headstream, the Apurimac, rises in the mountains 115 miles northwest of Lake Titicaca, and another headstream, the Mataro, comes within 100 miles of the Pacific Coast opposite Lima and over 13,000 feet above sea-level. The headstreams water the most populous districts of Peru, but the main course lies in the wild, forest-covered lowlands. It has a length of about 1,500 miles, more than half of which is navigable for steamers. Its principal affluent is the Pachitea which is navigable to a point about 300 miles distant from Lima.

UCCELLO, oo-chĕl'lō (PAOLO DI DONO), Italian painter: b. Florence, 1397; d. there, 1479. He began as a goldsmith and worker in metal, assisting Lorenzo Ghiberti (q.v.) in the first pair of gates made by the latter for the baptistery at Florence. His name of Uccello ("Bird") was given to him from the number of birds he kept as models for his pictures. Among the few works of his which have survived is a heroic-sized equestrian figure of Sir John Hawkwood in the cathedral at Florence, painted in terra verde (q.v.). In the Louvre there is a picture of his which is principally interesting from the fact that it contains life-sized portraits of Giotto, Donatello, Brunelleschi, Manetti and Uccello himself. In S. Maria Novella is a number of frescoes depicting scenes from Genesis and his 'Battle of San Romano' is preserved in the Uffizi. The Metropolitan Museum, New York, contains his 'Man and Woman of Portinari Family.' Consult Berenson, Bernhard, 'Florentine Painters of the Renaissance' (3d ed., New York 1909).

UCHEAN, ū'chē-ạn (adapted from *Uchee* or *Yuchee*), a linguistic stock of North American Indians who, in the 16th century, lived on both sides of the Savannah River as far as its mouth in South Carolina and Georgia. They are supposed to be identical with the "Cotifachiqui" of De Soto's chroniclers, whose principal settlement was at the site of Silver Bluff on the Savannah, in Barnwell County, S. C. In 1729 a portion of the Yuchees, as the one surviving member is called, left their old seats and settled among the Lower Creeks on Chattahoochee River, where they established three villages in the neighborhood; and later a Yuchee settlement is mentioned as existing on the Lower Tallapoosa, among the Upper Creeks. The tribe finally became practically a part of the Creek confederacy, and on the removal of the latter to the Indian Territory the Yuchees went with them. The surviving members of the tribe are usually classed as Creeks, but while the latter are doubtless intermarried with them, the Yuchees are jealous of their name and tenacious of their position as a tribe.

UCHIDA YASUYA, oo-chee-dä yä-sooyä, Japanese statesman: b. at Kumamoto, February 1865. Educated at the Imperial University of Tokio and graduate of the College of Law in 1887, he entered the diplomatic service as the attaché of the legation in Washington, served as secretary in the foreign office in Tokio and of the legations in London and Peking. In 1895 he was made minister resident in China. He served in other offices, at home and abroad, until, in 1899, he was made Vice-Minister of Foreign Affairs, and Minister to Peking in 1901–06, ambassador to Vienna 1907 and created baron. He was sent to Washington in 1909 and in 1912 called to be Minister of Foreign Affairs in the Saionji cabinet. He was again dispatched to Washington as ambassador, a public dinner in his honor being tendered to himself and wife by the Japan Society of New York. In 1916–17 he was ambassador at Petrograd and in 1918 was made Minister of Foreign Affairs in the Hara cabinet.

UCKEWALLISTS, ŭk-ĕ-wol'ĭsts, a religious sect so denominated after the name of its founder, Uke Walles, native of Friesland, who in 1637 published his opinion regarding human salvation. He taught the doctrine of Universalism, and held that the period between the birth of Christ and the descent of the Holy Ghost was one of profound spiritual darkness and ignorance, during which the Jews were deprived of divine illumination, and that, therefore, their rejection of the Messiah and their complicity in the Crucifixion would not be visited with the uttermost penalties by Divine Justice. After the death of their founder, the Uckewallists became merged in the Mennonite sect.

UDAIPUR, oo-dī-poor', or **ODEYPORE**, India, (1) A northwestern town, capital of a native state of the same name in Rajputana, 70 miles west of Gwalior. It is finely situated beside a lake 2,000 feet above sea-level, contains a notable royal palace, and exports cotton, indigo, etc. The old fortresses guarding the city are now in a dilapidated condition. Pop.

47,587. (2) The state (called also MEWAR), with an area of 12,756 square miles, came under the protection of Great Britain in 1817, and the raja ranks highest in dignity among the Rajput chiefs. Pop. 1,293,776.

UDAL, the name of a system of land tenure common in northern Europe before the feudal system. It is now preserved in Orkney and Shetland. The tenure was completed by undisturbed possession and provable by witnesses before a court. Though dependent on the Crown the incumbent pays only a slight tax known as *skat.* The tenure has been held by the English Court of Sessions to be equivalent to allodia; and the lands under it have been generally converted into fens. Consult Stubbs, William, 'Constitutional History of England' (Vol. I, 6th ed., Oxford 1897).

UDALL, ū'dal, or **UVEDALE, Nicholas,** English scholar and dramatist: b. Hampshire, 1504; d. London, 23 Dec. 1556. He was educated at Winchester and Corpus Christi College, Oxford, from which he was graduated in 1524. He is said to have imbibed Lutheran opinions and to have been on this account prevented from getting his M.A. degree until 1534. He now became headmaster at Eton, a post which he held till 1541, when he was dismissed. He continued, however, to hold till 1544 the vicarage of Braintree to which he had been appointed in 1537, and he gained the favor of Catharine Parr, queen of Henry VIII. Under her patronage he translated part of Erasmus' 'Paraphrase of the New Testament.' He was also in high favor at the court of Edward VI and held more than one benefice. On the accession of Mary he continued to maintain himself in favor and from 1554 till shortly before his death was headmaster of Westminster. Udall is now only remembered by his comedy 'Ralph Roister Doister,' a somewhat rude work in rhymed verses licensed in 1566 but probably written as early as 1540 and acted by the boys of Saint Mary's College, Eton. Several editions of this earliest of English comedies have since appeared, among them one in Arber's 'Reprints' (London 1869) and one in Dodsley's 'Old Plays' (1874). Consult Ward, A. W., 'English Dramatic Literature' (Vol. I, rev. ed., London 1899).

UDINE, Giovanni da, jō-vän'nē dä oo-dē'nē, Italian painter: b. Udine, Northeast Italy, 1487; d. 1564. He was originally a pupil of Giorgione at Venice and there did much decorative work. Afterward he was associated with Raphael in frescoing the loggias of the Vatican and the Villa Farnesina. His work here completed, he returned to Udine in 1527 and painted many pictures for that city and neighboring places, executing the frescoes in Colloredo Castle. He also furnished the designs for the stained glass windows in the Biblioteca Laurenziana at Florence.

UDINE, North Italy, capital of the Udine province (ancient Utina), 83 miles northeast of Venice, forms a kind of double town — an outer and an inner — both surrounded by walls. It contains a castle (now barracks) on an eminence, a cathedral. archbishop's palace, museum, technical institute, etc. All these structures are of great interest both historically and architecturally. The silk industry is important and there is a considerable trade, especially in flax and hemp. Leather, metal ware, paper, velvets and silks are manufactured in Udine. The city was the military base of the Italians in the war with Austria 1915–18. Pop. 47,617. On 29 Oct. 1917 the city was occupied by the Austrian armies. See WAR, EUROPEAN.

UDO, a plant (*Aralia cordata*) of the ginseng family, native of Japan. The young shoots, after being blanched, are used in much the same ways as asparagus, also in salads. Udo is grown extensively in Japan and has been introduced into the United States in recent years.

UEBERWEG, ü'bĕr-vĕg, **Friedrich,** German philosophical writer: b. Leichlingen, Rhenish Prussia, 22 Jan. 1826; d. Königsberg, Prussia, 9 June 1871. He was educated at Göttingen and at Berlin and in 1862 became extraordinary professor at Königsberg. He was appointed to the chair of philosophy there in 1867 and remained in that position until his death. He published 'System der Logik und Geschichte der logischen Lehren' (1857); 'Ueber die Echtheit und Zeitfolge der Platonischen Schriften' (1861); 'Grundriss der Geschichte der Philosophie' (1863), etc. Consult Lange, F. A., 'Friedrich Ueberweg' (1871); Brasch, 'Die Welt und Lebensanschauung Friedrich Ueberweg's nebst einer biographisch-historischen Einleitung' (Leipzig 1889).

UFA, oo'fä, Russia, (1) capital of the government of the same name, on the Bielaya, at the confluence of the Ufa, 735 miles east by north of Moscow. It is defended by a citadel; is the see of a bishop and has a number of handsome and regular streets and considerable manufactures and trade. Pop. 103,485. (2) The government was separated in 1865 from Orenburg; area, 47,130 square miles. On the east, where it is bordered by the southern Urals, the country is mountainous, wooded, provided with excellent pastures and rich in minerals. It is well watered by the Bielaya with its tributaries and has abundance of good arable land. To the west of the capital the country becomes flat and to the south steppes prevail. While very healthful the climate is severe. Copper, coal, iron, petroleum and sulphur are produced in small quantities, mining being yet largely undeveloped. Rye, oats and wheat are extensively grown and dairy farming is advanced. Kymiss is an important product. Pop. 2,988,500, comprising about 1,400.000 Russians and the remainder Bashkirs, Meshtcheryaks and Tatars.

UGANDA PROTECTORATE, a British East Africa protectorate lying north of Lake Victoria Nyanza and bounded on the north by the 5th parallel of north latitude, dividing it from the Egyptian Sudan, on the east by Lake Rudolf and the British East Africa Protectorate, on the south by Victoria Nyanza and East Africa (late German colony) and on the west by the Belgian Kongo. Its total area is 109,119 square miles, including 16,377 square miles of water. For purposes of administration Uganda is divided into five provinces (a) the Eastern province, comprising the districts of Busoga, Bukedi, Teso, Lango, Karamojo and Lobor; (b) Rudolf province, comprising the districts of Turkwel, Turkana and Dabossa; (3) Northern province, comprising the districts of Bunyoro, Gulu, Chua and West Nile; (d) the

Western province, comprising the districts of Toro, Ankole and Kigezi; and (e) Buganda province, with islands in Lake Victoria, comprising the districts of Mengo, Masaka, Mubendi and Entebbe. With the exception of the Rudolf province and the districts of Karamojo and Lobor, the whole protectorate is at present under direct administration; but the native kings and chiefs, whose rights are in some cases regulated by treaties, are encouraged to conduct the government of their own subjects. The province of Buganda is recognized as a native kingdom under a kabaka, who is assisted in the government by three native ministers and the Lukiko, or native assembly. In Buganda and in Bunyoro, Ankole and Toro purely native matters are dealt with by the Lukiko, but in certain cases there is an appeal to higher courts. For Europeans and non-natives justice is administered by English courts.

Topographically Uganda is greatly diversified, having great plains, forests, swamps, deserts and snow-capped heights. Rudolf province is very hot and although it has an elevation of over 2,000 feet it is very barren. The most fertile portion of the protectorate lies to the north of Victoria Nyanza, although the climate here is unhealthful and fraught with malaria. The part adjoining the Belgium Kongo on the west has well-forested hills and fertile plateaus and the climate is healthful. There is a peculiar native grass, much used by the natives as thatch, which often reaches a height of 12 feet or over. Lions and leopards, antelopes, wild cattle and crocodiles are numerous. Iron ore has been found in several districts and gold has been found in the north. Cotton is now grown in ever-increasing quantity. In March 1917 the total population of Uganda was 2,954,861, comprising 2,950,504 natives, 3,548 Asiatics and 809 Europeans. Among the natives approximately 600,000 belong to the intelligent, civilized Baganda, a race converted to Christianity in the 19th century. Education is in the hands of missionary societies, French (Catholic) and English (Anglican), to which the government grants about $6,000 yearly for scholarships for students and teachers. The Bantu languages are spoken by about 1,700,000 natives, a few Kongo pygmies live near the Semliki River, the remainder of the natives are of the Masai, Nilotic or Sudanese stocks. In 1917 the total imports amounted in value to about $6,500,000 and the exports to $5,380,000. The principal imports were textiles and yarns, $1,600,000; foodstuffs, $700,000; cotton, blankets, $150,000; sacks, $120,000; soap, $122,000; bicycles, $84,000; petroleum, etc., $75,000; agricultural implements, $75,000; clothing, $60,000. Exports consisted mainly of cotton, $1,800,000; coffee, $560,000; chillies, $135,000; ghee, $90,000; rubber, $29,000.

In 1917 the revenue of the protectorate was $1,577,290 and the expenditure $1,446,540. The headquarters of the British administration is at Entebbe; the native capital of Uganda is at Mengo, Kampala. Nile steamers from Khartum ply to Rejaf, which is about eight days' march from Nimule, the northern boundary of the protectorate. A regular steamer service is maintained by the Uganda Railway Administration between Kisumu, the railway terminus, and Entebbe, Port Bell and Jinja, all on Lake Victoria. The Busoga Railway Marine deals with traffic on Lake Kioga. There is also a steamer and subsidiary craft plying on Lake Albert and the Nile between Butiaba and Nimule. The Busoga Railway, 62 miles long, joins Jinja, on Victoria, to Namasagali, a point on the Nile below the rapids. There are also a railway between Port Bell and Kamfala and a number of motor transports. The protectorate has 1,373 miles of telegraph line and there are telephone exchanges at Entebbe, Kampala and Jinja.

The currency is based on the Indian rupee and consists of silver rupees with a subsidiary coinage of 50- and 25-cent pieces and minor coins of nickel. British sovereigns also are in circulation.

The territories now included in the protectorate came under British influence in 1890 and a portion of them was for a time administered by the British East African Company. In 1894 a British protectorate was declared over the kingdom of Uganda and some of the adjoining territories and the area was gradually extended to the present limits. Speke first visited the region in 1862 and in 1875 H. M. Stanley passed through it.

UGOLINO, oo-gō-lē'nō (DELLA GHERARDESCA), della gā-rär-dēs'kä, COUNT OF DONORATICO, Italian leader: b. Pisa, about 1220; d. there, March 1289. He was one of the leading Ghibellines of Pisa, but, with the purpose of obtaining supreme power in the Pisan republic, entered into a conspiracy with Giovanni Visconti, head of the Guelfs. Banished by his own party, he was later allowed to return. When subsequently Pisa was threatened by the Genoese under Oberto Doria, Ugolino was appointed to command the defense. In the battle of Meloria, 6 Aug. 1284, he fled, thus deciding the contest overwhelmingly in favor of the Genoese. Treachery on this occasion has been generally imputed to him, but it has also been asserted that there is no adequate evidence for this view. However that may have been, the Pisans now granted Ugolino his opportunity and by naming him capitano and podestá, at first for one year and later for 10 years, made him practically dictator of the state. Lucca and

Florence joined Genoa for the spoliation of Pisa, but Ugolino, not without extensive cessions of territory, drew them from the alliance. More fully to obtain the confidence of the Guelfs, he made Nino Visconti associate-podestá. The latter, however, plotted with the Archbishop Ruggiero Ubaldini for Ugolino's overthrow. In July 1288 he was besieged in the Palazzo del Popolo and compelled to surrender. His death by starvation in prison was related by Dante, who, in a passage to which Ugolino owes most of his fame, places him above the Archbishop Ruggiero on the inward margin of the second division of the lowest (ninth) circle of the Inferno. The narrative was paraphrased by Chaucer ('Monk's Tale') and translated by Medwin with the assistance of Shelley (consult appendix to Dowden's edition of Shelley). Consult Del Noce, 'Ugolino della Gherardesca' (1890).

UGRIAN, a term used in ethnology and comparative philology with somewhat different denotations. In ethnology it usually denotes a group of peoples of Mongolian stock extending from the rivers Ob and Ural in the east to the Baltic and the Danube in the west and south, and is thus an alternative name for Ugro-Finnish or Finno-Hungarian. In the science of language Ugrian, Ugro-Finnish or Finno-Hungarian describes one of the great main branches of the Ural-Altaic (otherwise Turanian) group of languages. The Ugrian languages have no grammatical gender and cases of nouns denoting locality are richly developed. Possessive suffixes take the place of our possessive pronouns. The verb has in general but two tenses, one for completed and the other for uncompleted action. Some of the Ugrian languages, such as Hungarian, have an objective conjugation of the verb, in which the personal object is expressed by a suffix. Most of these languages have a special negative conjugation, in which the negation is conjugated while the verb remains unaltered. See FINNS; HUNGARY.

UHDE, Fritz von, German historical and genre painter: b. Wolkenburg, Saxony, 22 May 1848; d. 1911. For a while a student in the Dresden Academy, he left the institution to enter the Saxon army, in which he fought during the Franco-Prussian War and became captain of cavalry. He resumed art at Munich (1877), but soon went to Paris, where he was a pupil of Munkácsy. After a period of genre-work in the old Dutch style, he turned to sacred subjects, abandoning modern artistic traditions in that field and presenting his themes in a contemporary guise, somewhat after the fashion of the mediæval painters. This, together with a certain dullness of composition, long prevented the recognition in many ways due him. His pictures, however, found their way into many German galleries; he obtained several distinctions, including a Munich professorship; and his ideas influenced considerably the trend of German art. Among his works are 'Come Lord Jesus, Be Our Guest' (1885; National Gallery, Berlin); 'The Last Supper' (1886); 'The Sermon on the Mount' (1887); 'The Organ-Grinder's Arrival' (1883); 'Drum-Practice' (1883); a 'Last Supper' (1897) for the Stuttgart Museum; 'Richard III'; 'The Ascension' (1898); 'Woman, Why Weepest Thou?' (1900), for the Vienna Museum; and 'Going Home' (1908). Consult the monograph by Von Ostini (1902); Rosentrogen in *Klassiker der Kunst* (Stuttgart 1908).

UHL, ool, **Edwin Fuller,** American diplomat: b. Rush, N. Y., 14 Aug. 1841; d. Grand Rapids, Mich., 17 May 1901. He removed with his parents to Michigan in 1844, was graduated from the University of Michigan in 1862 and was admitted to the bar in 1864. He was prosecuting attorney for Washtenaw County in 1871–72 and in 1876 removed to Grand Rapids, where he engaged in law practice until his election as mayor of that city in 1890. He was re-elected in 1891 and in 1893 he was appointed Assistant Secretary of State. While *de facto* Secretary of State during the illness of Secretary Gresham he was entrusted with the arbitration of the boundary dispute between Brazil and the Argentine Republic. He was Ambassador to Germany in 1896–97 and then resumed his law practice.

UHLAND, oo'länt, **Johann Ludwig,** German lyric poet: b. Tübingen, 26 April 1787; d. there, 13 Nov. 1862. He studied jurisprudence at Tübingen and was for a time an advocate at Stuttgart, subsequently giving his attention to linguistic pursuits. His earliest poetry dates from 1800 and the first collection of his poems appeared in 1815. In this year also he began to attract attention as a patriotic song-writer in connection with the political changes of the day, particularly those affecting his native state of Württemberg, 'Vaterländische Gedichte' appearing in 1816. In 1818 his tragedy, 'Ernst, Herzog von Schwaben,' appeared, and in 1819 another drama, 'Ludwig der Baier.' His fame, however, rests on his songs and ballads, several of which are among the most renowned in German literature, and are well known in English through translations by Longfellow. In 1819 he was elected by his native town of Tübingen, and later by Stuttgart, to the assembly of the states of Württemberg, and in 1830 was appointed extraordinary professor of German languages and literature at Tübingen, but resigned this appointment in 1833 to take his place as a representative in the assembly. In 1848 the electoral circle of Tübingen elected him their representative in the German National Assembly. Among his antiquarian works are 'Ueber das altfranzösische Epos' (1812); 'Ueber Walther von der Vogelweide' (1822); 'Ueber den Mythus der Nordischen Sagenlehre vom Thor' (1836); 'Alte hoch-und niederdeutsche Volkslieder' (1844–45; 3d ed., 1892). Consult the edition of his scientific works edited by Holland, Keller and Pfeiffer as 'Scripten zur Geschichte der Dichtung und Sage' (1865–72) and the several editions of his poetical works entitled 'Gedichte und Dramen.' An edition of his poems, together with his life, was published at Stuttgart in 1863. Consult Bernherdt, 'Uhlands politische Betätigung' (1910); Hartmann, A., 'Ludwig Uhland' (Stuttgart 1913); Jahn, 'Ludwig Uhland' (1863); Notter, 'Ludwig Uhland' (1863); 'Ludwig Uhlands Leben, von seiner Witwe' (1874); Fischer, 'Ludwig Uhland' (1887); Diederich, 'Uhland als Dichter und Patriot' (Gotha 1886); Paulus, 'Ludwig Uhland und seine Heimat' (1887).

UHLANS, oo'lans or ū'lans, a variety of light cavalry introduced into central Europe by

the Tatars. They were armed with sabre, lance and later with pistols. Just under the point of their lances hung gaily colored cloth, meant to frighten the enemy's horses; the lance itself was carried in the left hand and attached by a strap under the left shoulder. The Uhlans were adopted from the Tatars by the Poles, Austrians, Russians and Prussians. The last-named nation used them with great effect in the Franco-Prussian War, in which they won brilliant victories by their bravery and marvelous activity. In the War of 1914–18 the Uhlans of the Prussian service covered themselves with ignominy by their wanton acts of cruelty, plunder and rapine in the march through Belgium and northern France.

UHRICH, ü-rēk (Ger. oo'rĭH), **Jean Jacques Alexis,** French soldier: b. Pfalzburg, Lorraine, 15 Feb. 1802; d. Passy, France, 9 Oct. 1886. He was educated at the military academy of Saint Cyr, France, and in 1823 served in the campaign in Spain. He subsequently served in Africa, was appointed brigadier-general in 1862 and in the Crimean War became general of division. In 1862 he became grand officer of the Legion of Honor, and at the outbreak of the Franco-Prussian War was assigned to the command of Strassburg. Notwithstanding the importance of the post it was inadequately garrisoned and fortified, but when the Germans demanded its surrender in August 1870 Uhrich refused. In the bombardment which followed the Germans hurled 200,000 balls and shells into the city, yet its commander stoutly resisted the siege until 27 Sept. 1870, when, convinced of the impossibility of holding the city, he surrendered. His defense won high praise from the German officers and in recognition of his services he was awarded the Grand Cross of the Legion of Honor. He wrote 'Documents relatifs au siège de Strasbourg' (1872).

UHRICHSVILLE, ū'rĭks-vĭl, Ohio, village in Tuscarawas County, on the Stillwater Creek, and on the Pittsburgh, Cincinnati, Chicago and Saint Louis and the Baltimore and Ohio railroads, about 100 miles south of Cleveland and the same distance northeast of Columbus. It was founded in 1833 and was called at first Waterford; the name was changed to Uhrichsville in 1839. It is an agricultural and stock-raising region, and in the vicinity are deposits of clay. The chief industrial establishments are connected with clay products as brick, drain-tile and sewer-pipe. There are extensive shipments of clay products, wool and farm and dairy products. The city has several churches, a high school, public graded school and a school library. Coal-mining is extensively carried on. Pop. 4,750.

UINTAHITE, ū-ĭn'tą-hīt, a very pure and highly lustrous variety of asphaltum from the Uintah Mountains, Utah. See GILSONITE.

UINTATHERIUM, ū-ĭn-tą-thē'rĭ-ŭm, one of the huge horned ungulates of the group *Amblypoda,* fossil in the Eocene strata of the Uintah Mountains of northeastern Utah, whence the name "Uinta-beast" is derived. They were massive, five-toed, rhinoceros-like animals, with heavy heads, an ample dentition, with very large canines, like short tusks, from the upper jaw, and four or more pairs of horns upon the skull, supported by large cores. Closely allied were *Tinoceras, Coryphodon,* etc.

UIST, wĭst, **North** and **South,** Scotland, two islands in the Hebrides, south of Harris, and separated from each other by the island of Benbecula. North Uist is about 18 miles long, with a breadth varying from 4 to 10 miles. South Uist is about 21 miles and has a width of about 8 miles. The soil is fertile. Cattle-raising, fishing and agriculture are the chief occupations. Pop. (North Uist) 3,753; (South Uist) 5,109.

UITLANDERS, oĭt'lăn-dẹrz, or **OUTLANDERS,** the name given by the Boers, prior to the South African War of 1899–1902, to the foreign residents of the Transvaal, the majority of whom were British subjects attracted by the discovery of gold in 1886. The refusal of the Transvaal government to give them the franchise resulted in the extinction of the South African Republic. See SOUTH AFRICAN WAR; TRANSVAAL COLONY.

UJI-YAMADA, oo-jē-yä-mä-dä, the sacred city of Japan, where are the great Shinto shrines, which for over a thousand years have been the centre of national and ancestral worship. To this place of peerless sanctity, the emperor, after every important event, sends a message to make announcement to his ancestress, the Sun goddess. Uji and Yamada, formerly separate, form now one municipality, with railway, electric cars and lights and modern edifices. It produces lacquer-ware, chopsticks, flutes, paper pouches for tobacco, umbrellas, etc. The shrines, parks and places of interest attract many thousands of pilgrims annually. Pop. 40,357.

UJIJI, oo-jē'jē, or **KAVELE,** East Africa, a town in the Ujiji district, situated on the northern part of the east shore of Lake Tanganyika. It is the principal trading post on the lake, and a station for steamers. It is reached from Dar-es-Salaam on the coast, 743 miles away, by a railway. It was here that Stanley found Livingstone in 1871. Pop. 8,000.

UJJAIN, oo-jīn', India, a town in Gwalior, on the Sipra, 350 miles northwest of Bombay. It is six miles in circumference, and was formerly surrounded by a stone wall with round towers. It is the ancient capital of Malwa and contains Scindia's palace, a poor edifice. It has a considerable trade in opium, cotton and grain. Pop. 39,890.

UJVIDEK, ooy'vē-dāk, Hungary. See NEUSATZ.

UKASE, ū-kās', under the empire, a Russian term applied to edicts whether legislative or imperial. The term was not extended to the orders of the ministers. Ukases had the force of laws until annulled by subsequent edicts and many such orders were issued in the course of one reign. In 1827 Emperor Nicholas had the great mass of accumulated ukases collected, collated and codified. This code, called the svod, published in 48 volumes, with the modifications of subsequent ukases codified annually, formed the body of the Russian law until the establishment of the Soviet government in November 1917. Imperial orders for a day such as military orders during a campaign were called prikases.

UKIAH, ū-kī'ą, Cal., city, county-seat of Mendocino County, on the Russian River and on the San Francisco and North Pacific Railroad, about 120 miles northwest of San Francisco. It was founded in 1857. It is in an agricultural and stock-raising region. The industries are connected chiefly with the cultivation and shipment of farm products, hops and fruit. Considerable lumber and livestock are shipped to other markets. The educational institutions are a high school opened in 1893, public and parochial schools. Pop. 2,136.

UKRAINE, or UKRAINIA ("borderland" or "march-land"), a great undetermined region in eastern Europe, embracing most of the southern part of Russia in Europe, East Galicia, Northwest Bukovina and Northeast Hungary. The territory may be regarded as a geographic unit standing on an equal basis with the regions known as Great Russia, North Russia, the Ural, White Russia and the Baltic provinces. During the early days of the Russian Revolution a Ukrainian Congress was opened at Kiev in April 1917, when the policy was adopted of national territorial autonomy within the future Russian Federal Republic. The boundaries of the new state were to be the Pripet on the north, the Black Sea and the Sea of Azov on the south, the Kuban River on the east and the provinces of Lublin and Grodno on the west. A Rada (central council) was formed, which issued a manifesto of autonomy in June 1917. The advent of Bolshevism altered the situation. On 20 Nov. 1917 the Rada proclaimed the Ukranian People's Republic, transferred the land to the peasants, defined the limits of the new state and defied the Bolsheviki. The new republic allied itself with Rumania, Bessarabia, the Donetz Cossacks and the anti-Bolshevik General Kaledin. In December Trotzky sent an ultimatum threatening war unless the Rada ceased to bar the passage of the Bolshevik troops. There was considerable fighting between the two forces, and on 8 Feb. 1918 the Bolsheviki claimed to be in military and political possession of Ukraine and that the Rada had ceased to exist. But that legislative body had sent a delegation to the Brest-Litovsk Peace Conference and had announced (11 Jan. 1918) that the Ukraine had resumed its international existence as an independent state. The delegation was ultimately recognized by Trotzky, but when it began negotiations for a separate peace with Germany and Austria, he protested and introduced some Soviet delegates from the Ukraine. The Austro-Germans, however, recognized the Rada delegates as representing an independent state, and at 2 A.M. on 9 Feb. 1918 the Central Powers signed peace with the Ukrainian republic.

Area and Population.— It is not possible as yet to define with any degree of exactitude the limits, area and population of the Ukraine. Authorities differ on the subject, and at the present time (August 1919) the republic is conducting a double war against the Poles and the Bolsheviki, the issue of which may result in territorial changes. The state roughly corresponds with the three divisions of southern Russia known as the Southwestern Territory, Little Russia and New Russia, excluding the territory of the Don Cossacks. According to the treaties of Paris (June 1919), which annulled the Brest-Litovsk and all other Russian treaties concluded by Germany since November 1917, the provisional boundaries of the Ukrainian republic were — on the north, the republic of White Russia; northeast, the Soviet or Bolshevik republic of Russia proper; east, the Don republic; south, the Sea of Azov, the Tauride (Crimean) republic and the Black Sea; southwest, the reconstituted kingdom of Rumania; west, the republics of Poland, Czecho-Slovakia and Hungary. It is divided into the governments of Chernigov, Ekaterinoslav (or Yekaterinoslav), Kharkov, Kherson, Kiev (Kieff), Podolia, Poltova, Taurida and Volhynia. These nine governments, cut out of what was Russian territory, cover an area of nearly 200,000 square miles. With the added territory taken from Galicia, Bukovina and Hungary, the total area of Ukraine reaches to about 328,200 square miles, of which the population is estimated at 33,000,000. Too much faith, however, should not be attached to these vital statistics, as "official" figures are either out of date or unreliable, being generally compiled in favor of the ruling race, while the estimates of private authorities differ considerably. In the first complete Russian census (1897) the total number of Ukrainians in the then Russian Empire was given as 22,400,000; an estimate in 1910 showed 28,900,000. In the former Austro-Hungarian Empire about 4,000,000 Ukrainians (nominally Ruthenians) dwelt in Galicia, Hungary and the Bukovina in 1910. There are, in addition, some 500,000 Ukrainians in the United States; 300,000 in Canada and over 50,000 in South America. Numerically, this race ranks sixth among the peoples of Europe, the five above them being the Germans, Russians, French, English and Italians. See RUTHENES.

Topography, Etc.— Ukraine covers a varied surface configuration, but on a large scale, not as in western or central Europe confined in a small area, for one may travel hundreds of miles in any direction without encountering any change of scenery. There are landscapes of high and central chains of mountains, picturesque hill districts and richly cut plateaus, marshy plains and steppes strewn with barrows. The closed group of plateaus extending from the foot of the Carpathians and the Polish part of the Vistula region to the Sea of Azov form the morphological nucleus of the Ukraine. To this group the names of Pontian Plateau and Avratinian Ridge are commonly but erroneously applied. This Ukrainian Plateau group (a more apposite title) is divided into the following sections: The Rostokh, between the San and Bug rivers; Volin or Volhynian, between the San and the Teterev; Podolia, between the Dniester and the Boh; the Pocutian, or Bessarabian Plateau, between the Dniester and the Pruth; the Dnieper Plateau, between the Boh and the Dnieper. The plateau character continues at the rapids section of the last-named river on the left bank where, at some distance, the last member of the plateau group lies — the Donetz Plateau. The plateau group is bordered on the north and south by two plain districts, the former consisting of adjoining lowlands — Pidlassye, Polissye and the Dnieper plain (with their extensions along the Donetz), and the latter of the long stretch of the Pontian

steppe-plain, which merges into the Caspian desert-steppe at the foot of the Caucasus. The Ukraine also takes in part of three European mountain systems — parts of the Carpathians, the little Yaila chain of Crimea and the western parts of the Caucasus. Altogether, more than nine-tenths of the whole territory is taken up by plains and plateaus; its western boundary extends beyond the defile of Poprad. The range of the Tatra is visible from the mountain country where the last Ukrainian villages lie. The territory reaches the Prislop Pass in the eastern part of the Carpathians, at that point where they are highest and most developed, though less than one-third of that mountain curve lies within Ukrainian national territory. It is only within the last 25 years that Ukrainian civilization spread to the Yaila Mountains of Crimea, three parallel ranges barely 100 miles long and separated by longitudinal valleys, along the southeast shores of the peninsula. The southern main range declines toward the sea in steep precipices, flat and rocky on top and intersected by deep gorges. The Caucasus forms the eastern boundary of the Ukraine and lies like a huge wall of rock between Europe and Asia.

Of the plateaus, the Podolian is the highest and most massive, though not lacking in fine scenery. Its surface is covered with a thick crust of loess, of which the uppermost layer has been transformed into the famous black earth (Chornozem) noted for its fertility. Centuries of exploitation has diminished the forests with the result that many springs and brooks have dried up and rivers have been almost obliterated, causing serious droughts in the hot, dry summers. The Pocutian-Bessarabian Plateau reaches the valleys of the Bistritza and Vorona in the sub-Carpathian region and passes over into the Pontian steppe-plain in the southeast. The western part (Pokutye) has a flat, undulating surface and a number of funnel-shaped depressions called Vertep (caves), famous for their beautiful stalactites of white alabaster. The southeastern or Bessarabian part is divided into narrow marshes by the flat valleys of the Pruth and Reut rivers. The Rostokh Plateau, also known as the Lemberg-Lublin Ridge, is a profusely cut, hilly, narrow plateau which merges on the south with the Podolian near Lemberg, where it becomes an erosive hill country. Toward the east it resolves itself into parallel hill ridges which gradually become lower and embrace marshy valleys. The soil is not very fertile owing to extensive sand and marl soil. The Volhynian Plateau is divided into several sections of different size by the swampy lowland of the Polissye. The surface soil is black soil only in the south, while many regions of loamy ground are rich in vegetable soil of considerable fertility. The hills have steep declines and flattened rocky peaks. The valleys of the rivers, broad, flat, with gentle slopes and marshy bottoms, differentiate the landscape from that of the Podolian, presenting a view of flat, wooded hills, slowly-flowing streams, marshes, marshy meadows and sandy ground. The Dnieper Plateau is parted into several sections by broad river valleys and broad depressions which traverse it. Its configuration is varied, rising south of Berdichiev to 1,000 feet, sinking constantly lower to the east and southeast by irregular stages. To the furthest west is a level plateau, where the tributaries of the Teterev, Irpen and Ross flow slowly in flat valleys through whole rows of ponds, entering the plain between steep granite banks. The declivity of the right bank of the Dnieper is torn by gorges, presenting the appearance of a chain of mountains. The aspect of Kiev and the Shevchenko barrow is one of the most beautiful in the whole country. Dropping constantly lower toward the southeast, the land rises again in the region of the source of the Samara and along the Donetz. Here begins the Donetz Plateau, the easternmost member of the group, stretching in a long flat ridge from N.W.W. to S.E.E. and extending a flat side-ridge to either side. The surface is level, declining flatly toward all sides and sprinkled with countless tumuli. The coalfields of the Donetz are the richest in what was once the Russian Empire. Here also are quicksilver mines and great deposits of rock-salt. A number of factories have sprung up in recent years. Zinc, lead, copper and gold are extracted.

The principal river system of the Ukraine concentrates in the Black Sea, which receives streams from north, northwest and east. The western boundaries of the country lie on the Baltic slope, while in recent times its colonization has reached parts of the Caspian slope on the Kuma and Terek rivers. The main river is the majestic Dnieper (1,300 miles), affectionately termed «Father Dnieper» and regarded as the symbol of the Ukraine, of its life and its past. During the spring floods all the islands, sand banks, swamps, meadows and river branches disappear beneath an interminable expanse of yellowish water, rolling slowly toward the south, leaving behind, as it recedes, a layer of fertile river mud. The Don River, of which less than a quarter lies within the Ukraine, was formerly an eastern border stream until the borders were extended into the Kuban region and to the Caspian Sea. Of the steppe rivers tending toward the Sea of Azov only the Yeia reaches its goal; the rest end their courses in lagoons. The Kuban (500 miles) receives many mountain streams from the northern Caucasus and carries its waters partly to the Black Sea and partly to the Sea of Azov, embracing the peninsula of Taman. Barely half of its course is navigable. The river Dniester (850 miles) possesses the greatest variety of distinct sections of river of all the Ukrainian streams. Rising in Galicia on the northeastern slope of the Carpathians, it receives numerous tributaries from that range and from Podolia — the Zlota Lipa, Stripa, Sereth, Zbruch, Smotrich, Uzhitsa, Murakhva, Yakhorlik, etc. Though navigable for about 500 miles of its course, the river has not become an important waterway. There are numerous smaller rivers, canals and streams, such as the Boh, Pripet, etc., besides lakes and lagoons, which form terminals for the weaker streams.

The Ukrainian climate is of a continental character, assuming an entirely independent character. The central European climatic zone ends at the western borders of the Ukraine, while the more rigorous eastern European continental climate, which obtains over all of White

Russia and Great Russia, covers only a small area in the northern Ukrainian territory. Winter is severe in the entire country, but far less variable than in central Europe or Russia. It is followed by a very short spring of about three weeks except in the northwest, where it is a little longer. The summer heat is considerable; May is as warm as July in England. Autumn is regularly very beautiful and comparatively warm, though as early as October warm, sunny days are followed by night frosts. In the Crimea, the sub-Caucasian country, southerly location and the proximity of the sea are apparent; winters are short and comparatively mild; the summer of five months with high temperature is followed by a long autumn. Mediterranean climatic conditions are found south of the Yaila and Caucasus Mountains. Here, on a narrow strip of land on the Black Sea the winter lasts less than a month; after a long spring follows a six months' summer, passing imperceptibly into a mild autumn. The dreariest climate is that of the Beskids and the Gorgani in the Ukrainian Carpathians, where a five months' winter and long periods of rainy weather in the spring and autumn encroach upon a short summer. Prevailing west winds bring Atlantic air into northern Ukraine; east winds in the south bear the influences of the Asiatic steppe climate, and sometimes increase to terrific snowstorms, causing great destruction to human and cattle life. Yet in November and December moist, warm south winds frequently come up from the Pontus, but the freezing east winds referred to predominate and are responsible for the severe winters in that region. East and south winds in the spring frequently bring heavy sandstorms which injure the crops. In the summer, however, west, southwest and northwest winds prevail, carrying moist Atlantic air and rain into the entire country. Rainfall is less than in central or western Europe, being greatest in the mountain districts. The heaviest falls occur in June.

Consult the invaluable works of Prof. Stephen Rudnitsky, the eminent geographer of the University of Lemberg, Prof. M. Hrushevsky, president of the Ukrainian Rada and the publications of the Ukrainian National Association and of the Ruthenian National Union, both of New York, for material not elsewhere accessible.

Flora and Fauna.— The plant and animal geography of Ukrainia is more varied than that of Russia, for within its borders the three main divisions of European plant geography meet — the Mediterranean division, the steppe region and the forest region, and three mountain regions. Forests cover barely one-fifth of the country — only the northern and northwestern borderlands, where many swamp forests are to be found. In the forest region are also luxurious meadows with thick grass and tree clusters, stretching through wide, flat river valleys. In the swamps regular moors, made up of peat mosses, alternate with meadow moors in which swamp grass and herb vegetation predominate. Practically all the rest of the Ukraine is occupied by the steppe region, down to the foothills of the Yaila and the Caucasus. The fertile black earth region extends longitudinally through the country, over three-fourths of its area. On the Sea of Azov and in southern Crimea the brown dry steppe soil, with islands of saline soil and a peculiar vegetation, inclined to absorb salt, prevails. These also occur elsewhere along the rivers and the seashore. Grasses and herbs predominate on the meadow steppes, the former of the *stippa* species and the other of a lily-like growth. Grass is luxuriant and abundant in the northern part of the steppe region, while high weeds and thistles form dense thickets. In spring the steppe presents the appearance of a gorgeous flower carpet, but the colors soon fade into brown and yellow under heat and drought. This type of vegetation is thinner in the south. Terraces of trees are found along river valleys, and forests of oak, maple, poplar, white beech, wild apple and pear trees are studded over the steppes. The ancient Ukrainians of the Kiev state rooted out great areas of forest and reclaimed the land for civilization. Greater variety of vegetation is found in the Carpathians, though in regard to flora the country possesses but few endemic species. The fauna differs slightly from that of the rest of Europe. Many species which were dangerous as beasts of prey or useful for food or skins have either been entirely exterminated by man or greatly limited in their multiplication. In the 16th century the Ukraine was so rich in bison, wild horses and deer that these were hunted merely for the sake of their skins, and only the choicest of the flesh retained. The wild horses that once roamed over the steppes in great herds are extinct; the Sagai antelopes have retreated to the Caspian steppe; the once ubiquitous bear is now confined to the Carpathians, Caucasus and the Polissye country, in which regions the lynx and wildcat are also found. Throughout the country all sorts of smaller predatory animals have survived, such as wolves, foxes, badgers, martens, polecats. Of the large herbivora the bison has survived in the forest of Biloveza under government protection; the stag only in the Carpathians and the Caucasus, and the moose-deer only in Polissye. In the woods are still many boars and roes. The beaver, formerly found on every river in the country, has now retreated to the most inaccessible swamps. Eagles and hawks exist only in the two great ranges; grouse and heath fowl hide in the dense thickets; cranes and herons are rare; water fowl, wild ducks, geese, coot and diving birds are still very numerous. Owing to the absence of scientific pisciculture the former wealth of fish has greatly diminished. Yet much fish is still taken — mainly pike, tench, carp, crucian, shad, etc. Sturgeon, sterlet and other sea fish which formerly came in great swarms up the Dnieper, Dniester and Boh rivers are seldom found to-day.

The domestic animals are the same as in central Europe. Only in the extreme south camels and buffaloes are added. The horned cattle belong chiefly to the so-called Ukrainian breed, distinguished by its gray color and its size, bony and strong-limbed. Hungarian cattle is widely distributed on the southwest borders. In recent years pure Dutch, Swiss and Tyrol breeds have been spread. The finest horses, the Ukrainian, have been raised by the Zaporog Cossacks and are noted for strength, speed and adaptability for all kinds of work. The Chornomoric variety is raised by the Kuban Cos-

sacks and is prized throughout eastern Europe for its high qualities. Another breed, the Hutzulian mountain horse, possesses great strength though of small stature, and is unsurpassed for mountain roads. The peasant horses of Galicia, Podolia and Volhynia especially, despite their somewhat clumsy appearance, are particularly adapted for the rough roads of their land. Donkeys and mules are rare, and very few goats are kept. In sheep the Ukraine, thanks to vast pastures, is the richest country in Europe. Besides the native breeds, foreign merino sheep are raised, especially on the steppes. Hogs are raised in great numbers, the Polish, Russian and native varieties. In barnyard fowl the Ukraine is the richest land in eastern Europe. Much honey is also produced, besides mulberry leaves, though the silkworm industry is unimportant.

Ethnography.— The Ukrainians are a Slav race which diverged from the common stock at a very early period and developed during the centuries into an entirely independent Slav nation, just as Poles, Czechs, Serbs and Bulgars have done. Of that great family the Ukrainians form the second largest branch. Their nearest relations are the Ruthenes (q.v.), who are true Ukrainians who had long been incorporated in the Austrian Empire and lived under Hapsburg and Hungarian rule, but temporarily reunited with the mother-country as a result of the European War. The old Ukrainian Empire of Kiev was as old as the Holy Roman Empire of the German nation, but while the political evolution of the western European nations was proceeding, the Ukrainians were hindered by reason of their geographical situation at the western portals of Asia, where they were subject to Mongolian invasion. Though a mixed race, its formation took place in a distant prehistoric past, while later admixtures were too insignificant to change the type materially. From the Vislok to the Kuban and from the Pripet to the Black Sea, the Ukrainian people constitute a uniform anthropological type, which has preserved itself in its purest state in one wide zone embracing the Ukrainian Carpathian lands, Pokutye, Podolia, the Dnieper Plateau and Plain, the Donetz Plateau and the Kuban sub-Caucasus country. Tall of stature, with long legs and broad shoulders, strongly tinted complexions, dark, thick, curly hair, rounded head and long face with a high and broad brow, dark eyes, straight nose, medium mouth and small ears, with strongly developed lower face — these characteristics differentiate the Ukrainians from their neighbors, especially the White and Great Russians and the Poles. They are among the tallest peoples of Europe; the finest physical types are those of the Kuban and sub-Caucasus, descended from the Zaporog Cossacks, who for centuries represented the flower of the people's strength. Under the old régime many of the Russian Ukrainians were enrolled in the guard regiments of the tsars. See SLAVS.

Language and Literature.— There had long been an impression that the Ukrainian language was a rural dialect of Polish, while Russian bureaucracy consistently encouraged the view that it was merely a Little Russian dialect of the Great Russian language. In recent times, however, the more scientific philologists have arrived at the conclusion that Ukrainian is not a dialect of Russian, but an independent language of equal rank with Russian, related thereto just as Bulgarian or Serbian, Polish or Bohemian. Two close analogies may be found in the Latin and Teutonic languages, e.g., Spanish and Rumanian are Latin languages, but are not Latin dialects; Flemish, Swedish and Dutch are Teutonic languages, but not German "dialects." When the first Duma in 1905 removed the restrictions on Little Russian publications which had been imposed in 1876, the Saint Petersburg Academy of Sciences emphatically declared that the two were independent languages of equal rank, as, for instance, English and French. To the Ukrainian, Russian is a foreign tongue and difficult to acquire. There are four dialects of Ukrainian — the North and South Ukrainian, the Galician or Red Russian and the Carpathian Mountain dialect. These are again subdivided into idioms, of which the North contains four, the South three, the Galician two and the Carpathian four, though all of them differ but little from each other. Despite many years of rigorous suppression, the Ukrainian language has been kept alive in all its richness, flexibility, euphony, comparative purity and wide range of expression.

Among Slavonic literatures only those of the Russians and Poles surpass the Ukrainian, which possesses a large store of popular poetry, epic folklore and pre-Christian religious and secular songs. This literature has been built up during nearly a thousand years, dating from the flourishing days of the Kiev Empire and surviving through five centuries of unremitting struggle against Tatar barbarism. Yet from those dark ages there remain legal, theological, philosophical, polemic and even dramatic monuments of literature composed in a jumbled macaronic language of mixed Church-Slavonic and Ukrainian. The impetus for a revival of Ukrainian literature was given by Kotlarevsky in 1798 through introducing the pure popular speech in his writings. A large number of poets and prose writers rose to more than local fame during the 19th century, chief among them being Kobylanska, Stefanyk, Vovchok, Shevchenko, Kulish, Fedkovich, Franko, Mirni, Kotsiubinsky and Vinnichenko. Science has also made considerable progress, as also have history, geography and philosophy, while two learned societies have been established at Lemberg and Kiev. The circulation of Ukrainian literature was forbidden by former Russian governments in the territories under their rule.

Agriculture.— Nearly 90 per cent of the people are engaged in agriculture in the Ukraine, which is fitted by nature to be one of the most valuable food-producing regions in the world. Owing to lack of education in scientific methods, however, agriculture is still in a very backward condition. Better conditions prevail in the western borderlands, where regular rotations of crops, artificial fertilizing and improved machinery have considerably raised the volume of produce with less expenditure of human energy. Agricultural co-operative associations are spreading branches over the country and performing useful work to raise the level of husbandry by means of tuition, advice and assistance. Under foreign rule much of the

land has accumulated in the hands of alien landowners, while the native peasant had perforce to be content with the less valuable "leavings." While the great landlords grew wealthier the peasants grew poorer and were for many years compelled to seek homes elsewhere, in Siberia, Turkestan, Caucasia and further afield in the American continents. The Russian community system of land ownership existing in parts has not proved conducive to encouraging labor on land which the actual tiller cannot call his own. Despite all these obstacles the Ukraine remains the greatest grain-producing country of Europe, excepting Russia. Wheat, rye, barley, oats, buckwheat, millet, Indian corn, beans, lentils, fodder, hemp, flax, sunflowers, rapeseed, poppy, sugar-beet in enormous quantities, tobacco, all kinds of vegetables and fruits, grape-vine in parts, etc., are raised in the Ukraine, besides which there is also a flourishing cattle-raising industry. See *Flora and Fauna.*

Minerals, Etc.— Some mention has been made of mineral deposits found in Ukraine. (See *Topography*). The more important items are iron, mercury and manganese. The only important coalfield is situated in the Donetz Plateau, and is one of the largest and richest in Europe. In petroleum and ozokerite the Ukraine is richer than any other European country. There are large peat deposits awaiting exploitation; salt production has grown to great proportions from the immense deposits in salt springs and lakes and mines of pure rock-salt. Other natural treasures include phosphorites, containing from 70 to 75 per cent phosphoric acid; kaolin or porcelain clay and fireproof clays; slate, lithographic stone, mineral paints, sulphur, pumice-stone, mill-stones, whetstones, chalk, gypsum, building stones, Devonian sandstone and granite gneisses, etc.

Manufactures.— Until recent years home industries predominated in the Ukraine, weaving being the most important. The steady encroachment of the factory system and introduction of machinery are gradually displacing many of the domestic industries, though among the latter that of producing cloth, woolens, linen, carpets, tapestries, etc., is still carried on throughout the country, where weavers may be found in almost every village, especially in Galicia. Rope, cordage and nets are produced in large quantities, while the wood-working industry comes second to the textile craft in magnitude. It includes carpentering, cabinet-making, cooperage, shipbuilding, wagon-building, turning, carving, ornamental boxes and picture-frame making. Basket-weaving, shoemaking, pottery, brick-making, stone-cutting and metal working are trades located in districts where the soil provides the raw materials. Leather is abundant and prepared in flourishing tanneries; horn combs, buttons and other small articles are made for export as well as home consumption. There are also numerous families devoted to painting sacred pictures. Among the many other branches of industries are those of petroleum refining, sugar manufacturing and refining alcohol distillation, beer brewing, milling, cotton and hemp production; lumber, iron and steel, cement, tiles, matches, cork and paper are worked or manufactured to a large extent by foreign capitalists.

The trade and commerce of the Ukraine are still in a backward condition; what there is rests almost exclusively in foreign hands, Russians, Greeks, Armenians and Jews. Native competition against these more expert traders is as yet out of the question owing to the absence of educational opportunities. Another powerful drawback is the primitive condition of the means of communication in eastern Europe, which restricts or localizes most of the trade to small annual fairs, of which some 4,000 are held. The paucity of railroads and the bad state of the public highways render transport slow and difficult for horses and carts. Within recent years, however, some attempts at commercial organization have been made by the creation of exchanges and chambers of commerce in the principal centres to promote the exportation of raw materials. Since home industry covers the greatest part of domestic demand, the extent of foreign imports of manufactured goods is very small compared with the great export of foodstuffs which crosses the Ukrainian borders. Under the Russian régime the national resources of the Ukraine were exported in enormous quantities to other parts of the empire, while the Ukraine region was flooded with the inferior goods of central Russian industry. At the same time an annual customs balance of about $100,000,000 went to the central government from the Ukraine to be used for the development of the central provinces. In addition to this serious drain the Ukraine raised about one-third of Russia's total cattle supply, five-sixths of the empire's total sugar-beet output, 60 per cent of the whole coal production and one-sixth of the world's manganese supply. Yet with all this boundless natural wealth which his country provided, the Ukrainian peasant was left in grinding poverty, illiteracy and lack of proper clothing; he supplied the necessary manual labor in return for a pittance inadequate to maintain a decent existence. Centuries of oppression and political dependence resulted only in hindering the material and spiritual development of one of the naturally wealthiest countries in the world.

Cities, Towns and Settlements.— The largest city and most important seaport of the Ukraine is Odessa (q.v.), situated on a deep, open roadstead 20 miles north of the Dniester outlet. Kiev (q.v.), with over 500,000 inhabitants, comes next. It was the capital of the ancient Ukrainian kingdom and its spiritual centre; it is still called the Jerusalem of the nation. Other populous settlements are Kharkov, Chernigov, Ekaterinoslav and Zhitomir. See RUSSIA; GALICIA; POLAND.

History.— The historical life of the Ukrainian nation has differed entirely from that of the Russians or the Poles. Its roots lie in the ancient kingdom of Kiev, called "Old Russia" in the history books, and which formed a state erected by the southern group of the Eastern Slavic races, particularly by the Polan race around Kiev. A government existed early in the 9th century, and in 988 A.D. Greek Christianity was accepted by Vladimir the Great, the "Great Prince of Kiev," and all his peoples. From this period began a great advance in the material and intellectual civilization of the people; a high degree of commercial prosperity was attained while as yet the Russian lands lay wholly undeveloped. From Kiev Christianity

spread northward and eastward. During the 13th century the Tatar invasion under Genghiz Khan brought disaster to Ukrainia: Kiev and other cities fell in flames, the plains were desolated and thousands of the people were carried into captivity. Of the remainder, those who were not killed either starved to death or sought refuge in Galicia. After the barbarian wave receded, the fugitives or their descendants returned to their motherland, but in the meantime other Slav states had risen on the north. These latter coveted the fertile plains of the south and possessed the strength to bring them under their sway. The first of these states to exercise control over Ukrainia was Lithuania (q.v.), which ruled the land for 200 years, not without some justice and moderation. After 1569, however, Lithuania became united with Poland, and with the advent of the latter state to a predominant position in the union, the sorrows of the Ukraine increased under oppression and led to the inevitable revolt. Though Poland ruled with an iron rod, she was too weak, even together with Lithuania, to defend the Ukrainians against the sporadic raids of the Tatars, who issued from the Crimea, carried devastation as far as Galicia and Volhynia, and depopulated the region by the seizure of slaves and slaughter. This perennial warfare on the border forced the Ukrainians to take independent defensive measures. The farmers, hunters and fishermen on the marshy borders carried arms and led a precarious, half-industrial, half-military existence. They called themselves Kazaks (Cossacks), i.e., free warriors. These Ukrainian Cossacks created a military state organization in the 16th century around a strongly fortified position below the rapids of the Dnieper, the Zaporog Sich. Some notable features distinguished the Zaporog warrior state — absolute, democratic equality, obligatory celibacy and duly elected officials. In wartime unlimited power was vested in the highest official, the ataman or hetman, who then for the time being exerted the dictatorial sway of an autocrat. The Zaporog Cossacks were regarded by the entire Ukrainian people as their natural defenders alike against Tatar marauder and Polish political taskmaster. About the middle of the 17th century there was born the "Ukrainian problem" which lasted until near the close of the great European War in 1918. Toward the end of the 16th century the prevailing discontent led to a number of Cossack insurrections, culminating in the great Ukrainian revolution in 1648. After 100 years' constant struggle for liberation the Ukrainians threw off the Polish yoke, led by their hetman, the doughty Bogdan Khmelnyzki. Feeling itself unable to stand alone, the Ukrainian National Council (the Rada) made a treaty in 1654 with the Tsar Alexis of Muscovy, father of Peter the Great. That treaty brought the Ukrainians, figuratively speaking, out of the Polish frying-pan into the Russian fire, wherein they remained over 250 years. The treaty provided that the Ukraine should retain complete autonomy as well as their Cossack organization, the latter under their duly-elected hetman, with the right to conduct an independent foreign policy, while the military should stand under Russian suzerainty. But if the Ukrainian democratic ideals and form of government had been formerly obnoxious to aristocratic Poland, they were a still greater abomination to autocratic Russia. Three years after the signing of the treaty the liberator hetman died (1657) and Russia took the first steps toward crushing the national sentiments of the Ukrainian people and obliterating their democratic institutions. The incompetence of successive hetmans, jealousy and prejudice among Cossack officers, and the animosity of the poorer classes against the wealthy opened wide breaches into the national solidarity, which Russian officialdom did not fail to profit by. The autonomy of the Ukraine was gradually whittled away until, by the Peace of Andrussovo in 1667 with Poland, the country was split into two portions, one, that nearest to Poland, was ceded to that country, and the other, east of the Dnieper, was suppressed with unspeakable ferocity by Peter the Great after the failure of Mazeppa and the battle of Poltava. Ukrainia, as a nation, ceased to exist; the Zaporog Sich managed to exist till 1775, when it was destroyed; the people became serfs under the process of Russification and repression — a fate which also befell Poland a few years later, when the whole of that country, with the exception of Eastern Galicia and the Bukovina, which fell to Austria, was absorbed by Russia (1795). From this division of the country rose a dual Ukrainian problem — that of the Ukrainians under Russia and of the remainder under Austria, in which latter they fell under the domination of the Polish element in Galicia. Here even the name "Ukrainians" was superseded by that of "Ruthenes" (q.v.). In Russian territory the Ukrainians were officially designated as Russians and their language as a *patois* of Russian.

From this stage the history of the two severed portions of the Ukraine form part of the history of Russia or of Austria. But about the middle of the 19th century the Austrian government adopted a new attitude toward Galicia, intended to check Polish preponderance and to reduce the pressure of Russia on the east. This policy consisted in encouraging the ideal of Ukrainian independence, with the object of creating a powerful or at least a large buffer state by reviving the Ukrainian nation, in other words, uniting the Ruthenes with their brethren on Russian territory. Ruthenianism was fostered in Galicia by the foundation of professorships at Lemberg and the wholesale production of Ukrainian propaganda literature, which was circulated on the Russian side of the frontier. Toward the end of the 19th century the Ruthenians came to blows with their Polish overlords in Galicia, a conflict which the Austrian government could do little to suppress. In 1902 a general strike of Ruthenians broke out with the demand that Eastern Galicia be constituted a separate Ukrainian province. The Russian revolution of 1905 strengthened the movement against Polish suppression, and in 1908 the Polish governor of Galicia was shot dead by a Ukrainian student, who afterward escaped to the United States. Early in the European War the Russians overran Galicia and began the Russification of the territory by making the Russian language obligatory and forbidding the Ukrainian. In the following year, however, the Russians were expelled from Galicia by the Austro-German armies under Von Mackensen and the Central Powers made a bid for Polish support — Poland being also occupied by

them — with the promise of a reunited Poland under Austro-German patronage. This prospect alarmed the Ukrainians and led them to strive anew for independence. The Russian revolution of 1917, which swept away the Romanoff dynasty and finally developed into the greatest disorder under Bolshevism, gave them their opportunity. A national assembly, the Rada, was convened at Kiev, the old capital, in April 1917, and advocated a union with free Russia on a federal basis. Lvov and Kerensky, for the short time they were in power, opposed the plan. With the advent of Lenin and Trotzky, however, the Ukraine broke loose altogether from Russia, though maintaining a sympathetic connection with the Russian people struggling to found a genuine democracy. The Central Powers, being desirous of breaking up Russia, aided the Ukrainian movement, with the result that the Ukrainian nation was recognized as an independent state, which finally concluded a separate peace with Germany and Austria. Poland was not represented at Brest-Litovsk; her independence had been an article of faith of the Russian provisional government, while her self-determination was the policy of the Bolsheviki. The Ukrainians were divided on two distinct ideals. Their large peasant population was chiefly anxious to acquire the land from the great Polish proprietors, while in the towns there existed a strong intelligent nationalism. But the Bolsheviki were opposed to both desires. As Socialists they objected to the individualist peasant proprietors, and as centralists or internationalists they had little sympathy with provincial chauvinism. On 20 Nov. 1917 the Rada issued a proclamation, transferring the land to the peasants, establishing an eight-hour day, giving labor the control over industry and defining the frontiers of the republic. This bold attempt to forestall Bolshevism succeeded for the moment. The Ukrainians allied themselves with General Kaledin and the Cossacks of the Donetz basin, and with Rumania and Bessarabia. They occupied Odessa and fought steadily against the rising tide of Bolshevist troops. In December 1917 Trotzky sent them an ultimatum threatening war unless they ceased to bar the forces of Bolshevism, to which the Rada replied that they could not tolerate the interference of Bolshevik elements in their national government.

The collapse of Austria liberated the Ruthenians, who hastened to unite with their kindred over the Russian border, a program that was distasteful to the Polish nobility. With the Ukrainian occupation of Eastern Galicia a war broke out between them. The Poles recaptured Lemberg, which city was again besieged by the Ukrainians in January 1919. During March the Ukrainians again occupied Lemberg after several days' hard fighting and a siege of three months; they had captured Przemysl on the 18th and brought up their heavy guns to reduce Lemberg. The Ukrainians, headed by General Petlura, sought alliance with the Entente Powers to save them from Poles and Bolsheviki alike. The advance of the Bolshevist hosts upon Odessa during May was carried on with murder and rapine, turning the rich agricultural districts of the Ukraine into a wilderness. The rule of Bolshevism was introduced, with nationalization, confiscation and outrage. Instead of the Ukraine supplying the rest of Russia with grain, as Lenin had intended, that country was itself brought to the verge of famine. The Poles demanded that the new Poland should include Eastern Galicia on the ground that at least 35 per cent of the soil was owned by Poles. The natives objected that this ownership dated from feudal times and was manifestly unjust, seeing that the Ukrainian population was by far preponderant in the country. Early in June 1919, however, the Peace Conference authorized the military occupation of Eastern Galicia by Poland, "after having fixed with the Allied and Associated Powers an agreement whose clauses shall guarantee so far as possible the autonomy of this territory, and the political and religious liberty of its inhabitants. This agreement shall be based on the right of free disposition, which, in the last resort, the inhabitants of Eastern Galicia are to exercise regarding their political allegiance." The motive prompting the Conference appears to have been that of uniting millions of Ukrainians with Poland and Czecho-Slovakia, with a view to later junction with Rumania, thereby creating a great barrier between Germany and Russia in the future. The ancient title of hetman had been revived in May 1918 and conferred upon General Skoropadsky, a former general in the imperial Russian army. His attempt to hold the Ukraine for Russia with German aid failed. The National Union raised a volunteer army of 60,000 men and overthrew Skoropadsky. In August 1919 the Ukraine ceded Eastern Galicia to Poland and in September the anti-Bolshevist General Denikine recaptured Kiev for the Ukraine. Two months later the city fell again into the hands of the Soviet forces.

ULADISŁAS, or VLADISLAS, kings of Poland. There were seven monarchs of this name.

ULCER is a suppurating sore produced by the destruction of some part of the living structure, leaving a hollow from which matter is discharged. Ulcers may be either internal or external. They may be arranged either according to the constitutional or specific disease from which they are derived or according to the characters which they present. According to the first system ulcers are spoken of as healthy, inflammatory, strumous, etc.; while according to the second they are named irritable, chronic, sloughing, etc. A common, simple or healthy ulcer is such as is left after the separation of an accidental slough in a healthy person, and is merely a healthy granulating surface tending to cicatrization. Its edges shelve gently down to the base, and are scarcely harder than the adjacent healthy skin. Their surface near the borders is of a purplish blue tint where the young epidermis modifies the color of the healing granulations and within this the granulations have a deeper hue than those at the centre, being most vascular where the cuticle is being chiefly developed. The discharge from such an ulcer is healthy or laudable pus. The only treatment required is a little dry lint, if there is much discharge, or the water dressing, if the sore is comparatively dry. When the granulations are too luxuriant they must be touched with nitrate of silver and dressed with dry lint.

Inflammatory ulcers differ less than most kinds from healthy ulcers. They commonly arise from some trifling injury, such as a blow or slight abrasion of the skin, which to a healthy person would have done no harm. Their most common seat is on the lower half of the leg or shin. The surface is red and bleeds easily; the discharge is thin and watery; the edges irregular or shreddy; and the surrounding skin shows a red tinge, and is the seat of a hot and aching sensation. This ulcer most commonly occurs in the infirm and old, the ill-fed and overworked. Hence constitutional treatment, good diet and complete rest (with elevation of the limb) are here demanded in addition to a water dressing or lead lotion applied warm. Senile ulcers usually present very little discharge, exhibit granulations of a rusty red tint and are surrounded by a dusky red area. Nourishing food, wine, bark and the mineral acids are here required, and opium in small repeated doses is often serviceable. The local treatment must be of a stimulating nature, and in bad cases strapping the leg daily with a mixture of resin ointment and Peruvian balsam spread on strips of lint is recommended. Strumous or scrofulous ulcers usually occur as the consequence of scrofulous inflammation in the subcutaneous tissue or lymphatic glands. They most commonly occur in the neck, groins, cheeks, scalp and the neighborhood of the larger joints. The discharge is thin and of a greenish-yellow tint. These ulcers are seldom very sensitive or painful. The general treatment must be that recommended for constitutional scrofula. Iodine in some form or other is the best local application. A poultice of bruised and warmed seaweed is a very popular remedy; but there is probably nothing so efficacious as tincture of iodine diluted with water till it causes only a slight discomfort, and applied three or four times a day. Consult Adams, E., 'Treatment of Chronic Leg Ulcers' (New York 1914); Da Costa, J. C., 'Modern Surgery' (7th ed., Philadelphia 1914); Foote, E. M., 'Textbook of Minor Surgery' (New York 1914).

ULEABORG, oo'lyĕ-â-borg, Finland, town and capital of a government of the same name, at the mouth of the Uleå, on the northeast shore of the Gulf of Bothnia, 498 miles by rail north of Helsingfors. It has some manufactures and carries on a trade in timber, butter, grain, coal, iron, salt, raw hides, etc. Pop. 21,000.

ULEMA, the learned, knowing or wise: collective name of the body of theologians and legists in Mohammedan countries; the word is Arabic and the plural form of *alim,* learned, wise. The Ulema constitute the legal and judicial class and are interpreters of the Koran and of the laws derived therefrom; they are in Islam in a measure the counterpart of a hierarchy in a Christian monarchy, and are the principal check upon the irresponsible power of the sovereign. Every Mohammedan city has a body or Ulema, but the most renowned are the Ulema of Constantinople, of Mecca and of the Azhat University of Cairo. The Ulema of Turkey have the best organization, and enjoy many privileges and immunities. The classes of scholars and officials among the Ulema are the Imâms, or readers of the public prayers in the mosques; the Mûftis, or doctors of the law, who act either as advocates or as assessors in the courts; the Kâdis or Mollas, who are the regular judges; they are subordinate to two Chief Kâdis, one for the European, the other for the Asiatic provinces; over them all presides the Sheikh-ul-Islâm, spiritual head, under the caliph, of orthodox Mohammedanism.

ULEX. See FURZE.

ULEXITE, a mineral occurring in white, crudely spherical masses composed of fine fibres, having a silky lustre. It is very soft and light, its hardness being only 1, and specific gravity 1.65. It is a hydrous sodium and calcium borate, $NaCaB_5O_6.8H_2O$. It occurs in large quantities in Chile and Argentina, also abundantly in the salt marshes of Nevada and California. It is one of the commonest sources of borax.

ULFILAS, ULPHILAS, or **WULFILAS,** bishop of the Goths: b. north of the Danube, about 311; d. Constantinople, 383. He was consecrated bishop by Eusebius of Nicomedia, probably at Antioch, in 341; and though his native language was Gothic, he learned to speak and write Greek and Latin. Like all the Goths he was an Arian, and was called to Constantinople by the Emperor Theodosius shortly before his death to attend a conference or controversy on disputed matters of faith. His claim to renown is based upon the fact that he translated into his own tongue the whole Bible, with the exception of the books of Kings, which he deemed too warlike for his inflammable Goths. He seems to have invented the Gothic alphabet, which is evidently based on the Greek. He employed the Septuagint for the Old Testament, and a Greek text, different from the received text, for the New. His translation is faithful, but not slavish. It was generally used by the Goths who migrated to Spain and Italy, but the Gothic language hav-

ing died out in southern Europe it was entirely lost and only some fragments have been preserved. These consist of the greater part of the Gospels and epistles of Saint Paul, fragments of Ezra, Nehemiah, Genesis and of a psalm. The chief manuscript is preserved at the University of Upsala. There are editions of Gabelentz and Löbe (Leipzig 1843–46), Heyne (1896), Balg (1891), etc. This Gothic work is of the highest importance to the student of philology. (See GOTHIC; GOTHS). Consult Uppström, 'Codex Argenteus,' a facsimile (Upsala 1857); 'Fragmenta Gothica Selecta' (ib. 1861); 'Codices Gothic Ambrosiani' (Stockholm 1868). Consult also Bessell, W., 'Ueber das Leben des Ulfilas und die Bekehrung der Goten zum Christentum' (Göttingen 1860); 'Cambridge Mediæval History' (New York 1911) and Scott, C. A., 'Ulfilas: Apostle of the Goths' (London 1885).

ULLOA, ool-yō'ä, **Antonio de,** Spanish scientist and naval officer: b. Seville, Spain, 12 Jan. 1716; d. near Cadiz, Spain, 5 July 1795. He entered the navy when very young and in 1735 was appointed with Jorge Juan a member of the French scientific expedition to Peru. They were engaged for nine years in making surveys of the country, and in studying the history and social conditions of the inhabitants, upon which they made a secret report to the Spanish government. This document is of great historical value as showing the abuses which later resulted in the Revolution and was later published in English under the title 'Secret Information Concerning America' (1826). Ulloa was captured by the British on his return trip in 1744, but was shortly released and returning to Spain became prominent among Spanish scientists. He founded the first metallurgical laboratory in Spain and also established the observatory at Cadiz. He was appointed to various political offices of importance, and in 1766–68 was governor of Louisiana. He published 'Relación histórica del viaje á la América meridional' (1748); and 'Noticias Americanas' (Madrid 1772).

ULLOA, Francisco de, Spanish soldier and explorer in the New World: d. about 1540. He accompanied Cortes (q.v.) in the conquest of Mexico, and was sent by that commander (July 1539) to explore the Gulf of California. With three ships, one of which he lost in bad weather, he sailed from Acapulco for the Gulf. He was the first to establish the fact that Lower California is a peninsula. He ascended to the upper waters of the Gulf, explored the western coast of the peninsula and reached, by some accounts, lat. 30° 30′ N., by others only 28°. Statements as to his death are conflicting.

ULM, oolm, Württemberg, town situated 45 miles south-southeast of Stuttgart, on the left bank of the Danube and on both sides of the Blau, here crossed by five bridges. A bridge across the Danube connects with Neu-Ulm. It is a place of considerable strength, being provided with important defenses on both sides of the Danube. It is an old town, irregularly built, with narrow, winding streets. It has a cathedral in the old Gothic style, with spire 530 feet high, completed in 1890; manufactures of machinery, woolen and linen cloth, leather, ships, boats, pipes, pastry, paper, brassware, etc.; and an important trade. Ulm was long an imperial free town. It forms an important military position, and its possession has been keenly contested in every great European war, except that of 1914–18. The capitulation of Ulm, 17 Oct. 1805, was the turning-point of the campaign of Austerlitz. Pop. 56,100. Consult Loeffler, 'Geschichte der Festung Ulm' (Ulm 1883) and Schultes, 'Chronik von Ulm' (ib. 1886).

ULMANN, Albert, American author and stockbroker: b. New York, 2 July 1861. He was graduated from the College of the City of New York in 1881, and has been a member of the New York Stock Exchange from 1899. He has published 'Frederick Struther's Romance' (1889); 'Chaperoned' (1894); 'A Landmark History of New York' (1901); 'New York's Historic Sites' (1902); 'History of Maiden Lane' (1911); 'Tales of Old New York,' with Grace C. Strachan (1914), also editor of 'Historical Guide to the City of New York' (1909).

ULNA. See ARM; OSTEOLOGY.

ULPIANUS, ŭl-pĭ-ā'nŭs, **Domitius,** Roman jurist: b. Tyre, Phœnicia, about 170 A.D. His public life at Rome began under Septimius Severus, first as assessor to the prætor (Papinian), and afterward as *præfectus prætori* under Alexander Severus (222). He was murdered before the eyes of the emperor, whose adviser and mouthpiece he had been, by the Prætorian guard which he commanded (228). He was a voluminous writer and extracts from his writings form one-third of the 'Pandects' of Justinian, who makes 2,462 extracts from Ulpian. His chief works, 'Ad Edictum' and 'Ad Sabinum,' are only extant in fragments. Consult Hugo, 'Tituli ex Corpore Ulpiani' (1834); and Abdy and Walker, 'The Commentaries of Gaius and the Rules of Ulpian' (3d ed., Cambridge, England, 1885).

ULRICH, ŭl'rĭk, **Charles Frederic,** American artist: b. New York, 18 Oct. 1858; d. New York, 15 May 1908. He began the study of his profession at Cooper Institute and the National Academy. In 1879 he was awarded a medal at Munich, where he had been a pupil under notable artists for some time. He subsequently settled in New York, but in 1884 removed to Italy. His best-known pictures include 'In the Land of Promise'; 'The Glass Blowers'; 'The Wood Engraver'; 'The Carpenter'; 'The Waifs'; 'A Dutch Typesetter'; 'Washing of Feet in the Venice Cathedral' and 'Glass Blowers of Murano,' now in the Metropolitan Museum, New York City.

ULRICH, Edward Oscar, American geologist: b. Cincinnati, Ohio, 1 Feb. 1851. He was educated for a physician but abandoned medicine to become curator of the Cincinnati Society of Natural History (1877–81) and later was paleontologist to the surveys of Illinois, Minnesota and Ohio. After 1897 he was geologist of the United States Geological Survey. He also was associate editor of the *American Geologist* and author of many learned essays.

ULRICH VON LICHTENSTEIN, early German poet: b. Styria, about 1199; d. 1276. His chief work is entitled 'Frauendienst' and is valuable only as a history of the times. Con-

sult Becker's 'Wahrheit und dichtung in Ulrich von Lichtensteins Frauendienst' (Halle 1888).

ULRICI, ool-rē't'sē, **Hermann,** German philosopher and critic: b. Pförte, Saxony, 23 March 1806; d. Halle, Prussia, 11 Jan. 1884. He studied law, but from 1829 gave himself to philosophical study and became professor of philosophy at the University of Halle in 1834. He published 'Characteristics of Ancient Historiography' (1883); 'History of Poetic Art in Greece' (1835); 'Treatise on Shakespeare's Dramatic Art' (1839), a work much prized by Shakespearean students; 'On the Principle and Method of Hegel's Philosophy' (1841); 'Ground Principles of Philosophy' (1845); 'System of Logic' (1852); 'Glauben und Wissen' (1858); 'God and Nature' (1862); 'God and Man' (1866).

ULSTER, Ireland (Irish, *Uladh,* Latinized, *Ultonia*), the most northerly of the four provinces, comprehending the counties of Antrim, Armagh, Cavan, Donegal, Down, Fermanagh, Londonderry, Monaghan and Tyrone. Area, 8,613 square miles. At a very early period Ulster was a provincial kingdom and its southern boundary was farther south than it is to-day. The O'Neills and O'Donnells were the princely families of Ulster and they maintained themselves until the reign of Elizabeth. In the following reign the Irish title-deeds were declared void and Scottish Presbyterians were given the land, an injustice, the fruits of which have persisted to our day. According to the last census the principal religious professions in Ulster were Roman Catholics, 690,816; Protestant Episcopalians, 366,773; Presbyterian, 421,410; Methodists, 48,816; other professions, 53,881. Linen-weaving and shipbuilding, together with agriculture and stock-raising are the chief industries. See IRELAND.

ULTIMA THULE, ŭl'tĭ-mą thū'lē. See THULE.

ULTRA VIRES, ŭl'trą vī'rēz, a law term originated in 1851 by Baron Bramwell in the case of "East Anglian Railway Company vs. Eastern Counties Railway Company" (11 Common Bench, 775). It denotes the act or contract of a corporation beyond the powers conferred upon it in its charter. It is variously applied to its authorized acts performed in an unauthorized manner; its authorized acts performed by agents of the corporation unauthorized so to act; positively illegal acts of the corporation; but most specifically to its contracts to perform acts for which it is unempowered in its charter. The general rule is that *ultra vires* contracts cannot be enforced, and any stockholder or creditor can bring restraining suits against the corporation.

ULTRAMARINE, a beautiful and permanent blue pigment originally obtained by powdering and washing the rare mineral lapis-lazuli. It is now made by heating to bright redness mixtures of aluminum silicate (china clay or kaolin), sodium carbonate, sulphur and charcoal, and washing, powdering and sifting the product. It is supposed to be a compound of silicates and polysulphides. Largely used in dyeing, calico printing, in coloring soaps and as a paint pigment. The variety known as cobalt ultramarine is prepared from a mixture of cobalt arsenate and a fresh precipitate of alumina by drying and heating slowly to a red color. Barium chromate enters into the composition of yellow ultramarine.

ULTRAMICROSCOPE. An optical apparatus designed for the collective study of particles that are too small to be individually seen by methods formerly in use. It is not, properly speaking, a new instrument, but is merely an ordinary microscope provided with certain accessory devices for illuminating the field in a special way. It is well known that the possibility of seeing small objects by means of optical magnification is limited by the fact that light has a finite (though short) wave-length. The theory of the telescope indicates that the resolving power of the instrument — that is, its ability to reveal small details — increases in direct proportion to the diameter of the object glass. Similarly in the case of the microscope, theory shows that there is a limit to the fineness of the detail that can be seen, and it is known that this limit is determined by the numerical aperture of the objective and the wave-length of the light that is used — the resolving power being greater for high apertures and for short wave-lengths. In consequence of this theoretical limitation, it follows that no microscope, however perfect, can show an object in its true form and size, unless the diameter of the object is greater than about half the wave-length of the light by which it is viewed. In the case of an exceedingly small object diffraction phenomena become very marked; and when the diameter of the object is less than the limit indicated, these phenomena become so pronounced that the objective can no longer form a definite magnified image, corresponding in shape, size or details with such configurations as the real object may possess. If the particle to be observed is stationary, it may be photographed by means of ultraviolet light; and it is possible, by this means, to obtain somewhat more detail than can be perceived by the eye, which is sensitive only to light of a longer wave-length. No great gain can be made in this way, however, because there is a limit to the shortness of the wave-length of the ultraviolet light that can be used, and the most that we can reasonably hope for, in this direction, is to increase the visibility of detail sufficiently to enable us to learn something of structures having one-half or one-third the linear dimensions that can be directly perceived by the eye while using ordinary light. By means of the ultramicroscope, however, it is possible, under favorable conditions, to perceive, by the eye, particles having linear dimensions as small, for example, as 1 per cent of the wave-length of the light that is used. The *form* of these small particles cannot be discerned, on account of the limitation imposed by diffraction and noted above. They appear like circular discs, having an apparent diameter much greater than their real diameter. Yet notwithstanding the impossibility of ascertaining the real form of these particles, it is often useful to be able to demonstrate their existence and to count their number, ascertain their average mass and study their translatory movements; and these things can be done by the aid of the ultramicroscope. The principle upon which the ultramicroscope is based is exceed-

ingly simple. We see it exemplified in everyday life when a strong beam of sunlight traverses the air of a room that is otherwise dark or dim. As is well known, the beam, when examined from the side, reveals the existence of countless motes or particles floating in the air. Everyone of these brilliantly illuminated particles acts as a secondary source of radiation and hence can be perceived by the eye. Intent examination of a beam of sunlight under these conditions will show that some of the particles present are large enough for their forms to be seen with a certain degree of definiteness by the eye. There are many others, however, that are altogether too small for this, and these smaller particles are perceived merely as luminous points, without visible form.

The principle of the sunbeam and the mote-laden air is applied in the ultramicroscope without essential modification. In the form in which the instrument is applied to the study of liquids and of such solid particles as they may hold in suspension, a narrow but powerful beam of light is sent through the liquid in a horizontal direction, while the liquid is examined from above by means of an ordinary microscope provided with a water-immersion objective — the optic axis of the microscope being at right angles to the direction of the beam of light. By the aid of an arrangement of this sort, particles that are altogether too small to be perceived under ordinary conditions may be made to stand out like tiny luminous discs against a background that is either dark or at all events far less brilliant. In liquids, the particles that are thus seen exhibit active Brownian movements (q.v.). The size of the particle that can be seen is determined by the brilliance of the illumination. If the liquid under examination contains particles of every gradation of fineness, then with any given intensity of illumination the particles that are too small to be seen in their true form, but which are nevertheless large enough to be separately revealed by means of this method of observation, appear as small luminous discs. Particles that are too small to be separately perceived in this way under the given conditions of illumination reveal themselves, collectively, by communicating a hazy appearance to the beam of light.

Lord Rayleigh had shown, in 1899, that a particle that is too small to be separately seen by the microscope under ordinary conditions may, nevertheless, become visible if it is illuminated powerfully enough, even though it may be beyond the power of the microscope to reveal its true form. Dark-background illumination, in which the object is seen by reflected, refracted, diffracted or polarized light, and not by ordinary light that is transmitted directly through it, has also been familiar to microscopists for many years, and the Wenham parabolic substage condenser, in which the central rays are cut out by means of a central stop, while the oblique peripheral rays proceed upward at such a degree of angularity that they cannot directly enter the objective, has been a familiar accessory since 1872. In ultramicroscopy the principles of darkground illumination are merely developed scientifically and pushed to their ultimate limit; and the results that are obtained by observing exceedingly small particles under such conditions are studied with corresponding care. The method was first applied to the study of colloidal solutions by Seidentopf and Zsigmondy in 1903. Consult Zsigmondy, 'Chemistry of Colloids,' translated by E. B. Spear (1917; and for special technical details consult Cotton and Mouton, 'Les ultramicroscopes et les objets ultramicroscopiques' (1906) and Zsigmondy and Bachmann, W., 'Handhabung des Immersionsultramikroscops' (in the *Kolloidzeitschrift,* Vol. XIV, 1914).

ALLAN D. RISTEEN.

ULTRAMONTANISM, term which originated in France to designate certain policies, teachings and tendencies favored by the Church *ultra montes,* across or beyond the Alps, and opposed to the interests of the Gallican Church: later, Ultramontanism was used to denote the whole theological system of the Church of Rome and the doctrine of papal infallibility. Previous to the Vatican Council of 1869–70 Ultramontanism was an issue within the Church. At present it is extremely difficult to define the essential character of Ultramontanism, as it has manifested itself since 1870. Many Catholics have noted that within recent years over 70 per cent of the appointees to episcopal sees have been men who have made their theological studies in Rome and were in consequence imbued with ultramontane opinions, and would carry out the papalistic system, that is, the concentration of all power in the person of the Pope. Consult article 'Ultramontanism' in 'Realencyclopädie für protestantische Theologie und Kirche' (3d ed., 1908, Vol. XX, p. 213 et seq.).

ULUGH-BEG, oo'loogh-beg (or **BEIGH),** Mongol astronomer: b. 1394; d. 1449. He was the grandson of Timûr, or Tamerlane (q.v.); governed western Turkestan as regent for his father, Shah Rokh, while the latter was employed in regulating the affairs of the southern half of the empire, and succeeded in 1447 to the imperial throne on his father's death. He built at Samarkand an observatory where he prepared tables of the sun, moon and planets, and compiled the first original star-catalogue since Ptolemy, redetermining the position of 992 fixed stars. He wrote in Arabic, from which Persian translations were later made. This catalogue was edited in England by Hyde ('Tabulæ Longitudinis et Latitudinis,' Oxford 1665, etc.), and by Baily in 1843 (Vol. XIII of the Royal Astronomical Society's 'Memoirs', London 1843).

ULYSSES, ū-lĭs'ēz (Gr. Ὀλυσσεύς, *Olysseus,* "the hater"; Lat. *Ulixes*), Greek hero. He was king of the island of Ithaca, son of Anticlea and Laertes. He sailed with 12 ships in the Greek expedition against Troy. During the Trojan War (q.v.) he was noted for his eloquence, sagacity and prudence. He was, therefore, often chosen for the services of a spy. After Achilles' death, he received that chieftain's armor, the award driving Ajax mad. But he is best known through the series of adventures and misfortunes which the enmity of Poseidon compelled him to undergo during the 10 years of his return to "far-seen rocky Ithaca." This return is the subject of Homer's 'Odyssey' (q.v.). Odysseus, according to Homer, was thrown upon the coasts of Africa, and visited the country of the Lotophagi, and of the Cy-

clopes, in Sicily. Polyphemus seized him, with his companions, six of whom he devoured (see POLYPHEMUS); but the prince, having intoxicated him and put out his one eye, escaped from the cave. Æolus, whose island he visited, gave him a bag of winds to carry him home. His companions opened the bag, the winds escaped and they were driven back to the island of Æolus. Again sailing onward he reached a land inhabited by cannibal giants, the Læstrygones, from whom he escaped with only one ship. Then he was thrown upon the island Ææa, where Circe changed his companions into swine. Subsequently he passed along the coast of the Sirens and escaped the monster Scylla (who seized some of his men, however) and the whirlpool Charybdis. In Sicily his companions killed the sacred oxen of the sun, for which Zeus destroyed his ship by lightning, and all were drowned except Ulysses, who swam to Ogygia, the island of the nymph Calypso, where for seven years he had to remain. The gods at last interfered, and Calypso suffered him to depart on a raft built by himself. Poseidon raised a storm and sunk his raft. Ulysses swam to the island of the Phæacians where King Alcinous hospitably entertained him, and sent him home in a ship to Ithaca, after an absence of 20 years. He found his palace besieged by a set of insolent suitors for the hand of his wife, Penelope. With the aid of his son, Telemachus, he put the suitors to death. A portion of his adventures forms the theme of Stephen Phillips' striking blank verse play 'Ulysses' (1902); and Tennyson's noble 'Ulysses' is also concerned with the life of the Greek hero. Consult Lübker, Friedrich, 'Reallexikon des klassischen Altertums' (8th ed., Leipzig 1914).

UMA, oo'mă, in Hindu mythology, the consort of the god Siva. She is also usually designated under the names of Kâli, Durgâ, Devi (q.v.), Pârvati, Bhavâni, etc. This goddess is worshipped in various parts of India; but the textbook of her worshippers is the "Devimahatmya," or "the majesty of Devi"—a portion of the "Markandeya Purana," in which are detailed the martial feats of the goddess. These consisted chiefly in the destruction by her of two demons, Madhu and Kaitabha, who had endangered the existence of the god Brahman, in her victory over the demon Mahisha, or Mahishasura, who, having conquered all the gods, had expelled them from heaven; and the defeat of the army of Chanda and Munda. She is often represented holding the severed head of Chanda in her hand, with the heads of his soldiers formed into a wreath about her neck, and their hands spread into a covering for her loins. The worship of Kali (the Black), to which the narrative (of her victory over Chanda and Munda) has given rise, is considered by the Hindus themselves as embodying the principle of "tamas," or darkness. She is represented as delighting in the slaughter of her foes, though capable of kindlier feeling to her friends. She is, however, styled the Black Goddess of Terror, frequenting cemeteries, and presiding over terrible rites, fond of bloody sacrifices; and her worship taking place in the darkest night of the month. Her chief worship is in Bengal where her animal feast is one of the great religious and social events of the year. Max Müller (1823–1900) develops the myth of Uma into one of those solar myths suggested to the primitive mind by the most familiar of astronomical phenomena. Consult Barnett, L. D., 'Antiquities of India' (1913); Muir, John, 'Original Sanscrit Texts' (London 1873); Wilkins, W. J., 'Hindu Mythology' (London 1900).

UMATILLA, a North American Indian tribe of Shahaptian stock, who dwelt formerly near the confluence of the Columbia and the river which bears their name. They did not practise agriculture but found a means of subsistence in game, fish, fruit, etc. In 1804 they were visited by Lewis and Clark and in 1845 by Jesuit missionaries by whom they were converted to Christianity. Under a treaty of 1855 they were, with the Cayuse and Walla Walla, placed on a reservation near their old home. At present they number about 300.

UMATILLA RIVER, Ore., a southern affluent of the Columbia River, rising in the Blue Mountains, and after a west and northwesterly course of about 150 miles through Umatilla County uniting with the Columbia at Umatilla village on the boundary between Oregon and Washington. Pendleton, the capital of Umatilla County, is the chief town along its course.

UMBAGOG, ŭm-bă'gŏg, a lake, the greater part in New Hampshire, in Coos County, and part in Oxford County, Me. It is about nine miles long and from one to one and one-half miles wide. Its outlet is a short stream which enters Richardson Lake, in Maine. The scenery around Umbagog is most beautiful, and its waters are well stocked with trout and other fish. It is a favorite resort for sportsmen.

UMBALLA, ŭm-băl'a, or **AMBÁLA**, India. See AMBALA.

UMBELIFERS, or **APIACEÆ**, a family of herbs and a few shrubs popularly known as the parsley family. The species, of which about 1,500 have been described and grouped in approximately 200 genera, are most abundant in the north temperate and Arctic zones. Many species are also characteristic of high altitudes in more equatorial latitudes. The most notable feature of the family is the arrangement of the flowers in umbels, which characterize nearly all the species. The umbels are often compounded, that is, they are composed of smaller umbels called umbellets. The leaves are sometimes simple but generally compound, and usually contain resinous substances (volatile oils) which are characteristic of the individual species and either give or assist in giving the plants their acrid or pleasant flavors. In some species these flavors are very disagreeable, as, for instance, in asafœtida; in others pleasantly odorous, as in fennel and anise. These last two species and several others, such as parsley, caraway, coriander and celery (qq.v.) are popularly used for flavoring culinary preparations, such as salads, soups, sauces and dressings. The stems of celery have been greatly enlarged by cultivation, and are among the most esteemed salads, both in America and Europe. Several umbellifers have become important root crops in temperate climates. Of these the parsnip and the carrot are the best known in America, but several others are cultivated in Europe, Asia and southern Africa. Some of these, such as skirret

(*Sium sisarum*), and chervil (*Chærophyllum bulbosum*), are occasionally cultivated in American gardens. Many of the species, including those now cultivated as esculents, were formerly considered to have medicinal properties, but except in a few cases, such as fennel and anise, they have been discarded and in these cases they are now used merely to disguise the unpleasant flavors of other drugs. Formerly, also, many were reputed harmful and even poisonous when eaten by man and animals. Among these was the parsnip. The ill repute has been completely dispelled in most cases, but still clings to celery and parsnip; the former being reputed poisonous to certain individuals; the latter at certain seasons. Some of the uncultivated species are still under ban in some sections of the country but not in others. Besides the genera mentioned, the following are among the most important: *Crithmum, Archangelica, Conopodium, Smyrnium, Levisticum, Eryngium* and *Prangos*. Botanically the family has been found difficult to arrange satisfactorily. Coulter and Rose have described the American species; De Candolle, Koch, Sprengel, Engler and other Europeans have also devoted much attention to this large group.

UMBER, an olive-brown earthy pigment that becomes redder when heated. This earth is found in several localities; the best variety has come for some time past from Cyprus and goes by the name of Turkish umber. It is found also in Georgia, Illinois, New York and Pennsylvania. Raw umber is of an olive-brown color, semi-opaque, perfectly durable in water or oil, and does not injure any other good pigment with which it may be mixed. It is essentially a mixture of oxides of iron and manganese with 13 to 14 per cent of silica, together with small amounts of lime, magnesia, alumina, water, etc. When highly heated all the water is drawn off, causing a change in the brown hydrated ferric oxide to red ferric oxide, and also increasing the percentage of red-brown manganese oxide. The pigment is now called burnt umber. Raw umber is not subject to adulteration, but a ferruginous peat or brown coal from near Cologne is sometimes substituted for it. See PAINT.

UMBILICAL CORD, the bond of communication between the fœtus (which enters at the umbilicus, or navel) and the placenta, which is attached to the inner surface of the maternal womb. It consists of the umbilical vein, lying in the centre of the two umbilical arteries winding from left to right round the vein. Contrary to the usual course, the veins convey arterial blood to the fœtus, and the arteries return venous blood to the placenta. As soon as a child is born, and its respiration fairly established, the umbilical cord is tied, and divided near the navel, which spontaneously closes, the fragment of cord dying away. See FŒTUS; OBSTETRICS; PLACENTA.

UMBRA, the Latin word meaning shadow, was for the ancient Romans a person who attended a feast uninvited by the host but as companion of one that was invited, whom he followed as his shadow; this parasite's duty was to laugh at the jokes of his patron. *In astronomy*, the black central portion of a sun-spot was first called umbra by Dawes; he limited the designation nucleus to the patch of deeper blackness sometimes noticed in the umbra, though the whole of the darker area is often called nucleus: The fringe of lighter shade surrounding a sun-spot is called penumbra. *In ichthyology*, the solitary genus *Umbridæ* comprises two species: *U. krameri*, a small fish three or four inches long, found in stagnant pools in Austria and Hungary; and *U. limi*, rather smaller, locally distributed in the United States; its common name is dog-fish or mud-fish.

UMBRELLA, as its name implies, an instrument for casting shade. They were introduced from Asiatic countries, where they are of great antiquity, and are used as protectors from the sun's rays, rather than from rain. They were brought to England from Italy in the early part of the 18th century, and later came into general use, being employed by ladies, but scorned by men as effeminate, until Jonas Hanway, an eccentric traveler, demonstrated its utility as a protection from rain. They soon came into universal use. The general construction of umbrellas has changed little in the thousands of years it has been known, the ancient Chinese patterns being adopted by the Europeans. Gloria or alpaca in the common grades and silk in the finer ones have been substituted for the oiled paper once used for the covering, while grooved steel ribs have taken the place of the bamboo, rattan or oak ones. English manufactories control the largest output of the article and maintain a general excellence of quality. In Burma and Siam the umbrella is an emblem of rank. The Japanese have used umbrellas ever since their empire was established. In Greece they were used by ladies of position, and the Greek poets have reference thereto. In Rome women and effeminate men used them as a protection from the sun's heat.

UMBRELLA-BIRD, an extraordinary South American forest-bird (*Cephalopterus ornatus*) of the family *Cotingidæ*, which takes its name from its remarkable crest of feathers, the shafts of which, according to Wallace, radiate on all sides, reaching beyond the tip of the bill and forming a dome or parasol about four inches in diameter. The resemblance of this ornament to a helmet-plume has led to the name "dragoon-bird." Another curious feature is a cylindrical fleshy process, an inch and a half long, pendent from the front of the neck, and clothed with overlapping feathers. This bird is about the size of a crow and glossy black with a blue gloss on the crest. It inhabits the valley of the Amazon. In the Andine region occurs a second species (*C. penduliger*) with a much longer dewlap; and in Central America a third (*C. glabricolis*) in which the throat and dewlap are naked, except at the tip of the latter, and colored orange-red. These birds feed on berries and fruits, and have a loud, clear song. Consult Wallace, A. R., 'Travels on the Amazon' (London 1853); Newton, 'Dictionary of Birds' (New York 1896).

UMBRELLA-TREE, in eastern America, the larger species of *Magnolia*, and especially *M. tripetala*, or elk-wood. The latter's great, thin, oval leaves are pubescent beneath, nearly two feet long, and half as wide, and radiate from the ends of the branches, in a manner suggestive of the protecting ribs of an umbrella. It is a tree from 30 to 40 feet tall, with

irregular branches, and grows naturally in shady woods and in deep soil. The flowers are large and cup-shaped, with creamy tinted, thick petals, and reflexed petaloid sepals, and have a disagreeable odor. The tree, nevertheless, is sometimes planted for ornament, being completely hardy no farther north than Pennsylvania. The bark is slightly aromatic and tonic, but the wood is valueless. The ear-leafed umbrella-tree is *M. fraseri*, with auricled foliage and fragrant flowers. *M. macrophylla* is the great-leaved umbrella-tree. The pride-of-China-tree (*Melia azedarach*) has produced in the southwestern United States a variety, *umbraculifera*, which forms a regular, dome-shaped head like an open sun-shade, and is consequently to be added to the list of umbrella-trees. The Queensland umbrella-tree is the handsome araliaceous *Brassaia actinophylla*, a tree 40 feet high; that of Guinea is *Hibiscus guineensis*. A screwpine, *Pandanus odoratissimus*, is also known by this name.

The umbrella-pine, or parasol-fir, is a tall evergreen tree (*Sciadopitys verticillata*) from Japan, with a pyramidal habit. Its true leaves are reduced to minute scales, and its apparent glossy, dark foliage is composed of phyllodia, or stems assuming the functions of leaves, which are arranged in umbrella-like whorls on the branches.

UMBRIA, Italy, one of the ancient divisions of the peninsula, lying west of Etruria, and north of the country of the Sabines, and corresponding approximately to the modern district of the same name, in the province of Perugia. It is usually described as extending from the Tiber east to the Adriatic; but when the Umbrians first came into history they were restricted to the ridge of the Apennines, the lowland region bordering on the Adriatic from the Æsis (Esino) to the Rubicon being held by a race of Gallic invaders, known as the Senones. The Umbrians were subjugated along with the Etruscans, but joined the Samnites in their last gallant struggle against Rome, and were finally overthrown at Sentinum (295 B.C.). Later the Via Flaminia was constructed through Umbria and in the Augustan period Umbria was the sixth region of Italy. (See ITALIC LANGUAGES). The modern district formed part of the states of the Church until 1860. Its area is 3,748 square miles and a population of 686,500. The capital is Perugia, of which Leo XIII (then Mgr. Pecci) was archbishop for 32 years prior to 1878.

UMLAUT, oom'lowt, in philology, a modification of vowels; the change of the vowel in one syllable through the influence of an *a*, an *i* or a *u* in the syllable immediately following. It is common in Teutonic languages — German, Scandinavian and Anglo-Saxon; traces of it remain in English, as in the plurals of man (men), brother (brethren), mouse (mice), goose (geese), etc. In German the umlaut is seen in the frequent change of *a*, *o* and *u* to *ä*, *ö*, *ü*, as *Mann, Männer*; *Sohn, Söhne*; *Kraut, Kräuter*. Consult Henry, Victor, 'Short Comparative Grammar of English and German' (London 1894), and Lichtenberger, H., 'Histoire de la langue allemande' (Paris 1895).

UMNAK, oom'näk, an island of Alaska, one of the Fox Islands, a group of the Aleutian Islands. It is about 66 miles long and 10 miles wide. On the east is Umnak Pass, five miles wide, which separates the island from Unalaska Island. The interior was explored, in 1757, by Nikiforoff, a Russian. The island is of volcanic origin; the highest point, Vsevidoff, is a volcano 8,000 feet high. Other peaks are also volcanoes. Just north, and connected with Umnak by a reef, is the volcanic island of Bogosloff which was thrown above water in 1796. On Umnak are many hot springs; in one part the springs are boiling. Near Deep Bay there are springs which vary in temperature. Fossil-wood, lignite, fire-clay and different forms of lava are found on this island. The largest village, Nikolski, has about 300 inhabitants. The chief industries are catching seal and fishing.

UMPQUA, ŭmp'kwâ, a small tribe of the Athapascan stock of North American Indians. They now number about 100 individuals and are on the Grande Ronde reservation in Oregon.

UMRITSIR, ŭm-rĭt'sẽr. See AMRITSIR.

UN CURIOSO ACCIDENTE ('A Curious Mishap'), a three-act prose comedy in Italian by Carlo Goldoni, first produced, as the author's 'Memoirs' apparently indicate, in Venice in 1755 and generally regarded as his masterpiece. Nevertheless, the prestige given both in this country and elsewhere by Eleonora Duse to the author's 'Locandiera' ('The Innkeeper') has made the latter play better known to the theatre-going public than the former. Of the plays written by Goldoni in Italian 'Un curioso accidente' is certainly one of his best and one of the gems of standard Italian comedy. The simplicity of the plot is remarkable, consisting in the amusing misguided effort of a wealthy Dutch merchant to marry off secretly the daughter of one of his friends and, in the attempt, marrying off unwittingly his own daughter. Goldoni says in his 'Memoirs' (Part II, cap. 30) that the story of the plot is true, "that the curious mishap happened to a wealthy Dutch merchant, and was related to him by two of the merchant's Venetian agents." He goes on to add that "the piece had an entire success . . . and is still one of my favorite pieces." In another part of the 'Memoirs' (Part III, cap. 37) Goldoni relates that the play was translated into French by a Frenchman in 1784 with the title 'The Dupe of Himself,' that it was played the following year and proved a complete failure. The merit of the play lies in its extreme simplicity, in the sprightliness of the dialogue, few of the speeches containing more than three or four words or a line or two, in the amusing situations in Goldoni's best vein and in the artistic perfection of the construction of the comedy. Some of the scenes, for instance Act II, 8, are worthy of Molière. For American students of Italian, the edition of the play edited with English notes by Professor Ford of Harvard University is very useful and most readily available (Boston 1899). An English translation was published by the A. C. McClure Company in 1892 in the series 'Masterpieces of Foreign Authors.' This version was produced by Mr. Donald Robertson in 1907–08. 'Un curioso accidente' was performed in Italian under the auspices of the Modern

Language Department of the University of Toronto in 1917.

JAMES GEDDES, JR.

UNA, ū'nạ, in Spenser's 'Faerie Queene,' the allegorical representative of Truth, which in this "lovely ladie" shines forth in all its purity. By her gentle spirit she tames a lion (Reason), which accompanies her through her distressful wanderings. For her sake her companion, George, the Red Cross Knight, slays the dragon, and after a period of painful separation they are united in marriage.

UNADILLA, ū-nạ-dĭl'ạ, N. Y., village in Otsego County, on the Susquehanna River, and on the Delaware and Hudson Railroad, about 45 miles northeast of Binghamton and 93 miles southwest of Albany. It is in an agricultural region. The chief manufacturing establishments are a flour mill, creameries, machine shop, foundry and a wagon shop. The educational institutions are Union School and Academy, ranked as a high school, opened in 1893, and elementary and primary schools. There is one bank. Pop. 1,009.

UNAKA MOUNTAINS, a southwestern division of the Appalachian system, sometimes called in part the Great Smoky Mountains or simply the Smoky Mountains. They extend southward near the western boundary of North Carolina and Tennessee. The elevation of the range varies from 3,000 to 5,000 feet. They are well covered with pine trees and the slopes present a very picturesque aspect. Sandstone and shales with some metamorphic rocks make up the bulk of the range.

UNAKITE. A peculiar granite consisting essentially of yellow-green epidote, pink feldspar and quartz; occurs in Unaka Mountains, along North Carolina, Tennessee line and in Virginia. Used for ornamental work.

UNALASKA, oo-nā-lās'kạ, an island of Alaska, one of the Aleutian Islands, and the middle one of the Fox Islands. Two Russians, Glottoff and Soloiroff, with a small party of adventurers, lived several months on the island the winter of 1765–66. The island is often visited by whalers, sealers and explorers. It was an administrative centre, and is still one of the important parts of Alaska. A naval rendezvous is at Captain's Bay, at the northeastern end of the island. The island is volcanic; the highest point, Makushin, 5,960 feet, smokes constantly and occasionally it sends out lava. The vicinity is often subject to earthquakes. At Iliuliuk the thermometer is rarely above 80 degrees in summer or below zero in winter. The climate is too cool for much vegetation. Copper and iron abound. But few small animals are found. The largest town, Unalaska, on Captain's Bay, is an outfitting station for ships passing to and fro from the Pacific to the Arctic oceans. The area of the island is about 800 square miles. Unalaska has a population of about 1,200, Aleuts, Russians and Americans.

UNAMI ("people down the river"), a division of the Delaware Indians of Pennsylvania, who occupied the Delaware River from the mouth of the Lehigh to the Delaware boundary line. They were sometimes referred to as the Turtle tribe, in allusion to one of their totems.

UNAU, the two-toed sloth. See SLOTH.

UNCANOONUC MOUNTAINS. A small range of mountains in southeastern New Hampshire, rising rather prominently above the adjoining rolling lands to an altitude of 1,348 feet. Somewhat well known as a summer resort. They are reached by trolley line from Shirley and Manchester. Used as a station in a base line of the United States Coast and Geodetic Survey. They consist of granite and gneiss.

UNCARIA, a genus of climbing plants with hooked spines, of the order *Chinconiacæ,* and natives of the East Indies and tropical America. See GAMBIR.

UNCAS, ŭng'kas, Mohegan sachem: d. about 1683. He was originally a war chief of the Pequot sachem Sassacus, obtained the support of the English settlers and so acquired dominion over the Mohegan territory. In 1637 he joined the English in the war against the Pequots and received for his services another portion of the Pequot lands. He shielded many of the Pequots from the vengeance of the English when the war was over, and for this was for a time in partial disgrace with the authorities; but he was soon received again into so great favor with the whites that several attempts were made by different Indians to assassinate him. In 1643 he was victorious over the powerful Narragansett sachem Miantonomoh (q.v.) and in 1648 the Mohawks, Pocomtocks and other tribes unsuccessfully made war against him. He was besieged in 1657 by the Narragansett chief Pessacus, and is said to have been relieved by Ensign Thomas Leffingwell. In reward for this service it is said Uncas gave to Leffingwell all the land now included in the site of Norwich, Conn. In 1654 Uncas was reproved for "rapacity and injustice" by a council of colonial commissioners. He was the ally of the English in all the wars against the Indians during his life, though in King Philip's War he was too old to be of much active service. In 1842 a monument was erected in his honor at Norwich. Consult Drake, S. G., 'The Book of the Indians of North America' (1834); Stone, W. L., 'Uncas and Miantonomoh, a Historical Discourse' (1842). See COLONIAL WARS IN AMERICA.

UNCIAL LETTERS. See PALÆOGRAPHY.

UNCLE REMUS, a plantation negro, the assumed narrator of plantation and folklore stories collected by Joel Chandler Harris in such books as 'Uncle Remus: His Songs and His Sayings' (1880); 'Nights with Uncle Remus' (1882); 'Uncle Remus and His Friends' (1892), etc.

UNCLE SAM. See NATIONAL NICKNAMES.

UNCLE TOM'S CABIN, or **LIFE AMONG THE LOWLY,** a novel by Harriet Beecher Stowe (q.v.), the most important contribution of the emancipation movement to American literature, first appeared as a serial from 1 June 1851 to April 1852 in the *National Era,* an anti-slavery newspaper published at Washington, D. C. In serial form it attracted no particular attention, but after publication in book form, 20 March 1852, in a few weeks it achieved unusual success, finally attaining world-wide popularity, and being translated into over 22 different languages. For 18 years Mrs. Stowe lived in Cincinnati, where the problems of slavery were continually thrust upon her

attention, the river Ohio alone separating the city from Kentucky, where slaves bringing their tales of oppression and cruelty were continuously escaping from their masters in attempts to gain freedom in Canada. In the great moral, economic and political movements of the times Mrs. Stowe and her husband took an active part. They had removed to Brunswick, Me., where Mr. Stowe had been appointed professor in Bowdoin College, when the storm occasioned by the Fugitive Slave Bill arose. Inspired by the force of the human message which she felt she must deliver, with full-stored memory and vivid imagination, she wrote with fervor-glowing heat the novel as representative of certain phases of plantation life in the old South, which helped in no small measure the cause of emancipation. Few novels have ever aroused so much enthusiasm and indignation, so much criticism, favorable and unfavorable. 'A Key to Uncle Tom's Cabin,' including interesting notes, documents and testimonials appeared in 1853 as a reply to inquiries, censure and criticism, and the same year she also published 'A Peep into Uncle Tom's Cabin for Children.' Josiah Henson (q.v.) was the original of the character of Uncle Tom. Dramatized soon after its publication in book form, 'Uncle Tom's Cabin' still retains its stage popularity.

UNCLEANNESS, a ceremonial in various religious systems, symbolizing the lack of ritual purity of fitness. In the Brahmanic system food cooked by a Sudra or by an outcast is unclean to the Brahman; he loses caste if he eats of it; and he contracts ceremonial uncleanness if he consorts with unclean persons, as the Pariah, the Mahar or other outcasts. The hieratic law of Judaism pronounced certain animals unclean and, therefore, not to be eaten. Of animals that "chew the cud" all might be eaten, with exception of four; but of the four excepted — the camel, coney, hare and swine — the first only is of the class of the ruminants. Among birds declared to be unclean are the eagle, ossifrage, vulture, kite, etc., of which several cannot be positively identified; but at all events the birds of prey are certainly included among the unclean birds, while most of the grain-feeding birds are allowed as articles of food. Among fishes or aquatic creatures, those are unclean which have neither fins nor scales. Except the leaping orthoptera — locust, grasshopper, etc.— most insects are unclean, as also all creeping things, from vertebrate reptiles to molluscous snails. And not merely were unclean animals to be rejected as food, their carcasses were to be avoided, and whoever touched them became thereby unclean. The laws of ceremonial uncleanness were never of obligation in the religion of Jesus Christ, who taught that "not that which entereth into the mouth defileth the man; but that which proceedeth out of the mouth, this defileth the man"; and with regard to persons, Saint Peter, after the vision of the sheet let down, would no longer call any man common or unclean. Consult Benzinger, I., 'Hebräische Archäologie' (2d ed., Tübingen 1907), and Stade, B., 'Geschichte des Volkes Israel' (Vol. I, Berlin 1887).

UNCOMPAHGRE VALLEY PROJECT. The Uncompahgre Valley Project is one of the largest construction enterprises undertaken by the United States Reclamation Service under the Act of 17 June 1902. It effected the irrigation of 150,000 acres of arid lands lying on both sides of the Uncompahgre River in southwestern Colorado. It was accomplished by the diversion of the waters of the Gunnison River into the Uncompahgre Valley and the subsequent distribution of the water thus diverted, together with the waters of the Uncompahgre River, over the lands to be cultivated.

The engineering works connected with this project are as follows:

(1) The Gunnison Tunnel, which pierces the divide which separates the Gunnison River from the Uncompahgre River. This tunnel is 30,582 feet long and passes under the summit of the divide at a depth of 2,220 feet. The eastern portal of the tunnel lies in the grand canyon of the Gunnison River. It is reached by a wagon road 10 miles in length, which is one of the picturesque drives of Colorado. The western portal is located in the Uncompahgre Valley near Cedar Creek Station on the Denver and Rio Grande Railway.

(2) The South Canal, which carries the water from the Gunnison Tunnel to the Uncompahgre River; 12 miles in length. This canal contains four short tunnels and many masonry drops.

(3) The West Canal, which distributes the waters from the Gunnison Tunnel and the Uncompahgre River over the lands west of the Uncompahgre River; 30 miles in length.

(4) The East Canal, which distributes the waters from the Gunnison Tunnel and the Uncompahgre River over the lands lying east of the Uncompahgre River; 35 miles in length.

(5) Numerous auxiliary canals and laterals.

(6) Impounding reservoirs on the headwaters of the Gunnison River for the storage of flood water to supplement the regular flow of the stream during the dry months. Streams of the arid region derive their summer flow in the main from melting snows in the high mountain ranges. When the warm sun of the spring months begins to be felt the great body of snow on mountains and foothills disappears quickly in floods of more or less magnitude, depending upon prevailing seasonal conditions. During the summer months the flow depends upon the slowly-melting snow fields which lie in deep gulches and behind lofty precipices, where they are sheltered from sun and wind. This late flow is inadequate to the requirements, and to supplement it convenient basins are dammed and filled with flood waters to be released gradually when needed later in the year. To provide for this contingency sufficient reservoir sites have been segregated on the headwaters of the Gunnison River. These sites will be held and developed as future needs dictate. In addition to supplementing the irrigation waters these reservoirs will be useful as power producers.

The Uncompahgre Valley lies at about 5,000 feet above sea-level. It is sheltered by lofty mountain ranges and enjoys a mild and equable climate. The mountains surrounding the valley form a portion of the continental divide, and contain many of the richest gold, silver, copper and rare metal mines in the world. The soil of the valley is of unusual fertility. The principal products are apples, peaches, apricots,

prunes, cherries, wheat, oats, potatoes, sugar beets and livestock.

UNCONFORMITY, an erosional break in the continuity of deposition of sediments. When one stratum is deposited on the next in regular and unbroken order they are conformable. But when the surface of one bed is eroded before the next is laid down the two are said to be unconformable. If the beds are marine, that is, have been laid down in the ocean, an unconformity between them means that there was a period of emergence and erosion between the time of deposition of the first and second beds. It is by this means that we are enabled to work out much that is known about the distribution of land and water in past geologic time. Sometimes the older beds are folded as well as eroded, so that the younger lie horizontally above dipping beds below. This is called angular unconformity or discordance of bedding. If a region gradually sinks so that a series of beds are laid down above an old erosion surface in such wise that each succeeding bed covers a larger area and laps over from the bed on which it naturally rests onto the old erosion surface, we have unconformity with overlap.

UNCONSCIOUS CEREBRATION, term formerly in general use in mental physiology, to denote the action by the mental faculties (or the cerebral organs), as of memory, reasoning, etc., performed without the mind being conscious of what it does till the results of this unconscious action present themselves in the centres for consciousness in the new ideas or new combinations of ideas which were evolved in the unconscious process. The theory of unconscious cerebration has been current among German metaphysicians from the time of Leibnitz and was systematically expounded by Sir William Hamilton. See CONSCIOUSNESS.

UNCONSCIOUSNESS, a condition of little or no consciousness. The definition of consciousness (q.v.) has been given in another volume and it remains here to consider those degrees and kinds of deviations from ordinary conscious states, particularly in the subnormal depressions. Under unconsciousness may be grouped two or three types. There may be total abeyance, such as is seen in epilepsy, in sleep, in brain concussion, in severe injuries, in infectious diseases, in drugs, as anæsthetics, hypnotics, alcohols, etc. There may be subnormal conditions, semi-conscious, subconscious states which would properly be classed here, for in certain conditions, such as in some epileptics, some alcoholics or hysterics, consciousness at one time may be acute and yet all memory of the former state may be obliterated in another condition. Some of these conditions are grouped under the heading of double personalities. Some of these represent true phenomena, the vast majority are frauds. Thus from the minor forms of "absent-mindedness" through sleep, up to the deepest grades of unconsciousness produced by drugs, one can observe in life all the many steps of a large variety of unconscious phenomena. The site of consciousness has already been discussed and its coexistence with the entire nervous system maintained, but clinically it appears under many exciting causes. The most important of these are:

Unconsciousness due to

1. Convulsions of unknown origin.
2. Epilepsy.
3. Hysteria.
4. Organic brain diseases.
5. Organic heart diseases.
6. Toxic causes — poisonings, endogenous and exogenous.
7. Traumatism.

(1) In childhood convulsions with unconsciousness come on from a large number of unknown causes. Fear, anger, high temperature, teething, worms, are some of the actual irritants in many of these instances; but in many no cause, immediate or remote, is to be found. Many of these attacks resemble attacks of epilepsy. They are to be carefully watched to determine this point, otherwise much harm may come, particularly if they are mild epileptic attacks and the epileptic habit be engendered by carelessness in treatment. Sometimes these convulsions leave permanent brain injuries, but the majority recover without serious after effects. Convulsions in a child of unknown origin should mean to the mother that the nervous system is very readily upset and special precaution should be taken to avoid all forms of excitement in such children.

(2) Epilepsy. The most common form of unconsciousness in epilepsy has already been discussed (see EPILEPSY), but there are in some epileptics minor alterations of consciousness that are of much importance. In some epileptics the patient, while not truly unconscious, yet may be so engrossed in a dominating idea that all outside elements of attention are excluded. Thus some of this class may rob, murder, burn, roam off for days or even weeks, and yet on their return to their so-called normal conscious state, they may be absolutely oblivious to all that has happened. Such states are not uncommon in epileptics, but they are very rare outside of this condition and hysteria.

(3) Hysteria (q.v.). In this disease unconsciousness is rarely complete. Consciousness is altered. These changes are fully discussed. Also see INSANITY; PARANOIA.

(4) Organic Brain Disease. A number of brain diseases may cause unconsciousness. The most common are meningitis, hemorrhage, thrombosis, embolism, tumors, organic dementias. Under the general term apoplexy is included three separate disorders, all of which have similar symptoms. These are hemorrhage, embolism, thrombosis. In the one, a blood vessel in the brain breaks and there is destruction of brain tissue, in the second, a clot, usually from a larger blood vessel, is swept into a smaller blood vessel of the brain, cutting off the blood supply of a part of the brain. In a third a disease of the wall of the blood vessel causes a local clot which fills up the vessel and in the same manner deprives a part of the brain of blood. In all of these conditions a "stroke," or apoplexy, with unconsciousness occurs. The individual symptoms may be consulted under apoplexy, hemorrhage of brain, embolism, etc. In general paralysis of the insane, attacks of unconsciousness are a regular part of the development of the disease. See GENERAL PARESIS.

(5) Some forms of heart disease are attended with fainting attacks. In these the

valves of the heart are found to act in a defective manner. See HEART, DISEASE OF THE.

(6) For a consideration of the toxic causes of unconsciousness see article on TOXICOLOGY.

(7) Traumatism, such as blows on the head, severe falls, sunstroke, all give rise to unconsciousness. The two former conditions have been discussed under concussion — the last under sunstroke. See CONSCIOUSNESS; CONSCIOUSNESS, DISORDERS OF; CONSCIOUSNESS, BIOLOGICAL ASPECTS OF, and consult bibliography under the first of these.

SMITH ELY JELLIFFE, M.D.

UNCTION, anointing with oil as a religious or semi-religious rite, is traceable back to the rudest form of nature worship. The pillars of stone or of wood that were the symbols of phallic worship, as the sacred stone in every village of certain parts of India at present, had oil poured on the top of them. The custom of pouring oil on sacred stones was not unknown to the Israelitish race (Gen. xxviii, 18; xxxi, 13). In the Mosaic ceremonial the use of unction is expressly prescribed for various occasions; among the Jews there was a holy anointing oil prepared with perfumes (Ex. xxx, 22–23) with which the priests and the tabernacle with all its furniture were anointed; the kings also were installed in their office by unction; and the usage was retained in the Christian Church, being employed in the administration of the sacraments of baptism, confirmation, order, in the consecration of altars, of sacred utensils, etc., and in the coronation of sovereigns. See UNCTION, EXTREME.

UNCTION, Extreme ("the last anointing"), one of the sacraments of the Roman Catholic Church as also of the Greek Orthodox Church; it is a sacrament in which the sick that are in danger of death are anointed by a priest for the health of soul and body; its divine origin and sacramental character are inferred from the passage James v, 14, 15. The "matter" of this sacrament is "oil blessed by the bishop"; but in the Greek Church the priests, commissioned by the bishop, bless the oil. The "minister" of extreme unction is a priest, not any cleric in inferior orders. The "subject" of the sacrament is a person that is dangerously sick. The "form" consists in the prayers pronounced by the priest in administering the unction; for example, at the unction of the eyes, the priest prays, "By this holy unction and through his most tender mercy, may the Lord forgive thee whatsoever sin thou hast committed by sight."

UNDER-TENANT. See RENT, LAW OF.

UNDERGROUND MINING. See MINING.

UNDERGROUND RAILROAD, The, a term made common in the United States prior to the Civil War, denoting a secret method of conducting negro slaves from the Southern States to Canada and free States in the North. Between the Ohio River and the Great Lakes were many abolitionists who gave shelter and assistance to escaping slaves, and their homes were known as stations of the underground railroad. Among those who were patrons of the "underground" system were Wm. Lloyd Garrison, Wendell Phillips, Josiah Grinnell, Gerrit Smith, Theodore Parker, Thomas Garrett, Charles Torrey, Samuel May, Levi Coffin, T. W. Higginson and F. B. Sanborn. (See ABOLITIONISTS). Consult Siebert, W. H., 'The Underground Railroad from Slavery to Freedom' (New York 1899).

UNDERGROUND RAILWAYS. See SUBWAYS; TUNNELS AND TUNNELING.

UNDERGROUND RUSSIA, a noted work by Stepniak. The former editor of *Zemlia i Volia* (Land and Liberty), who for many years hid his identity under the pseudonym of "Stepniak" (freely translated "Son of the Steppe"), wrote in Italian, in 1881, this series of sketches of the revolutionary and Nihilistic movement in which he had taken such an important part. The introduction gives a succinct history of the individualistic propaganda which resulted in Russia in a certain measure of freedom for women, and which, at the expense of much suffering and many young lives sacrificed, spread a leaven of liberalism through the vast empire of the tsars. Stepniak traces the successive changes that took place in the attack on autocracy between 1871 and 1881. The movement reached its final goal in 1917, when tsarism went down under a crushing defeat.

UNDERGROUND TEMPERATURES. In the process of cooling the earth still retains a vast volume of heat. This heat is not appreciable at the surface where air temperatures prevail but it is manifest in deep mines and borings which show a general increase of temperature with depth. The rate of increase is by no means regular but varies from place to place and in some cases it changes with depth. In general it ranges from 40 to 80 feet to 1° F. and the average indicates that at a depth of 25 miles the temperature is about 2,200° F. or above the melting point of iron and rocks. It is difficult to conceive how great the maximum may be farther down. This heat is believed to be a residual of that which was present when the earth was in molten and gaseous conditions. Much has been lost by the cooling-off process that is still in operation. Volcanoes may be evidence of the general internal heat although it is more likely that they are manifestations of some local heat conditions probably developed at moderate depths.

A large number of observations have been made of underground temperatures in deep mines, wells, bore holes and tunnels in various parts of the world. Many of these have been taken with great accuracy and others are approximations. Some representative ones are given at the end of this article.

Rates of increase of earth temperature are calculated from the difference between the mean annual air temperature and the observed temperature at the given depth, it being assumed that the temperature for the first 50 feet below the surface is that of the mean annual air temperature. It has been found, however, that the latter figure is somewhat too low, the discrepancy varying with latitude and various local conditions. The difference is about 1½° in a humid climate like that of England and 2½° to 3¼° in a dry climate such as that of northern Africa. In some cases the temperature at some shallow depth is directly determined and used for the comparison. In many instances temperatures are taken of various depths and the results plotted in a curve which is independent of the

surface temperature. Many temperatures have been obtained of flows from deep artesian wells and also of flows from pumped wells. In these it is necessary to know the depth of the source of the water and the flow must be large in volume and long continued. The thermometers used are of several kinds but ordinarily self-registering maximum mercury thermometers or thermo-electric instruments are lowered in the borings or sunk in holes in deep mines. In deep holes, convection, gas expansion and heat from recent boring vitiate the result. The influx of deeper waters, proximity of recent volcanic rocks, lodes in which mineralization is in progress and planes or zones of movement have great influence, the last especially in facilitating rise of deep seated underground water. In mines, especially coal mines, oxidation materially increases the heat. In the upper part of the Anzin coal mines, in France, the temperature is 15° F. above the normal.

One of the most striking features of the rates of underground temperature increases as observed in borings and mines is their variation from place to place. Undoubtedly some of these variations are due to imperfect observations but most of them are related to local causes of which the nature is not known. Attempts have been made to show that rates are lower in the mountains, higher in petroleum areas and coal fields and various other general conditions but in most cases these relations are not borne out when many observations are assembled. There are undoubtedly in the earth many factors which influence the rate of temperature increase such as variation in conductivity of various rocks, underground tension, mineralization and movement of underground water. Local volcanic action of course is a most powerful agent but only present in certain areas where its influence generally is clearly apparent. Variation in radioactivity has been suggested as a factor, and the influence of bodies of cold water such as Lake Superior and former presence of glacial ice as causes of local diminution of earth temperature. Positive evidence is lacking along all these lines, however, and the results of extended special investigations must be awaited before the true explanation is attained.

Selected Observations in United States.

ALABAMA.— Many observations of temperature of flows, from deep wells show a range from 50 to 100 feet to one degree, a large proportion falling below 75 feet to one degree; at Mobile the rate is 71 feet to one degree.

ARIZONA.— In the Phoenix region the shallower wells show rapid rates, 20 to 40 feet to one degree and deeper ones average 60 feet to one degree. In the plateau north the rates range from 22 to 50 feet to one degree. The rate indicated by the more vigorous flowing wells in San Simon valley varies from 30 to 60 feet to one degree.

CALIFORNIA.— Flows from wells of moderate depth in the orange country of southern California vary somewhat in temperature, especially where there are local hot spring conditions; but the more closely accordant figures give rates near 50 feet to one degree. The many flowing wells in San Joaquin Valley show rates from 35 to 150 feet to one degree, but in the deep wells in the oil fields the range is from 27 to 91 feet to one degree. In Indio Basin most of the many flowing wells 400 to 700 feet deep show no increase in temperature. In Grass Valley gold mines the average rate is 114 feet to one degree.

COLORADO.— Flows from artesian wells in Arkansas Valley show rates from 23 to 54 feet to one degree, mostly from 30 to 40 feet. In San Luis Valley the rate is 22 to 32 feet. At Trinidad 42 feet, at Denver 33 to 52 feet, and at Akron 45 feet to one degree.

FLORIDA.— The great well at Saint Augustine showed a rate of 81 feet to one degree but other wells show rates varying from 43 to 100 feet and some are less.

GEORGIA.— Rates from 57 to 127 feet to one degree are indicated by wells but the data are not reliable.

IDAHO.— High rates of increase are recorded in the State

but most of the observations are in areas over or near young volcanic outflows.

ILLINOIS.— Many Illinois wells have mixed flows from various depths, but evidently the rate is low. Thermometers sunk at Saint John give a rate of 83½ feet and at Streater 97 feet to one degree.

INDIANA.— Data are not reliable but rates from 73 to 118 feet to one degree are indicated.

IOWA.— The flowing wells of Iowa indicate various gradients but most of the data are unreliable owing to mixed flows. Thermometers sunk at Des Moines and Ames gave rates of 109 and 116 feet to one degree respectively. At Davenport 75 feet and at Council Bluffs 83 feet to one degree.

KANSAS.— Most of the gradients obtained in Kansas varied from 50 to 75 feet to one degree, the deep shaft at Lyons Salt mine indicating 74 feet to one degree.

KENTUCKY.— The old deep well at Louisville has gradient of 81 feet to one degree according to one report and 106 feet to one degree according to another.

LOUISIANA.— In the 3,171-foot hole at Belle Island a thermometer sunk to a depth of 975 feet indicated a rate of 73 feet to one degree. In various flowing wells in the State rates are mostly 50 to 80 feet to one degree.

MARYLAND.— One observation at Crisfield on the Eastern Shore indicates a rate of 47 feet to one degree.

MICHIGAN.— It is a fact of great interest that the rate of temperature increase is usually low in the deep mines of the northern peninsula of Michigan, the average being about 125 feet to one degree. Deep wells in the southern peninsula show rates ranging from 45 to 70 feet to one degree. The 3,455-foot hole at Bay City, temperature 97° in bottom, indicates a gradient of 68½ feet to one degree.

MISSISSIPPI.— Flowing wells show varying rates from 43 feet at Biloxi to 211 feet to one degree at Vicksburg.

MISSOURI.— The data from Missouri while somewhat conflicting show low gradients. The 3,843-foot hole at Saint Louis Asylum indicates a gradient of 78 feet to one degree.

MONTANA.— Observations in Anaconda Mine at Butte show an average of about 50 feet to one degree while a flowing well at Miles City indicates a rate of 35 feet to one degree. Flowing wells in Little Bitterroot Valley show an average of 5½ feet to one degree, probably influenced by warm springs.

NEBRASKA.— The flowing wells in Missouri Valley in the northeastern corner of the State indicate rates of increase from 19 to 30 feet to one degree. The wells at Omaha have rate of 85 feet and at Lincoln of 57 feet to one degree.

NEVADA.— The detailed studies of Comstock Lode, made long ago, showed that the rapid rates of increase probably are influenced by volcanic conditions. The temperature of 170 degrees at depth of 3,100 feet indicated a rate of 28 feet to one degree. At Tonopah the rate varies from place to place and with depth and the average is near 40 feet to one degree.

NEW JERSEY.— Flowing wells along the sea coast show an average rate of 50 feet to one degree with exception of Wildwood well in which the rate is to 69 feet to one degree or more.

NEW MEXICO.— A well at Sandia not far southwest of Albuquerque showed a rate of 35½ feet to one degree.

NORTH DAKOTA.— Deep flowing wells in central and eastern North Dakota show rates ranging from 36½ to 56 feet to one degree with an average of 40 feet.

OHIO.— The 2,980-foot well at Findlay showed a rate of 95 feet to one degree with diminished rate as depth increased. The 2,775-foot hole at Columbus indicated 71 feet to one degree and 3,020-foot hole at Plymouth 69½ feet to one degree.

OKLAHOMA.— The rates in Oklahoma were found to range from 34 to 62 feet to one degree, the highest rate being in the central northeastern part of the State.

PENNSYLVANIA.— Several very deep holes in the western part of the State have been carefully tested for temperatures. The 6,299-foot hole 15 miles southwest of Pittsburgh with temperatures of "156° near bottom" (141.3° at 6,100 feet) indicated a rate of about 69 feet to one degree. The 429-foot hole at Homestead had a rate of 70 feet to one degree and the 5,380-foot hole at West Elizabeth 73 feet to one degree. In the anthracite coal field rates vary, most of them from 72 to 140 feet to one degree, a 1,598-foot drill hole at Glen Lyon showing 130 feet to one degree.

SOUTH CAROLINA.— The deep wells at Charleston show a rate from 56 to 61 feet to one degree.

SOUTH DAKOTA.— Several hundred determinations of temperatures of water from deep flowing wells in the eastern part of the State show some remarkable anomalies of variation from rates of 17½ feet to one degree, to 50 feet to one degree closely related to the configuration of the granite or quartzite floor of the artesian basin (consult Darton, N. H., 'Geothermal data in South Dakota,' *American Journal Science*, Vol. V, p. 161, and United States Geological Survey, 18th Annual Report, Pt. IV, pp. 606–611, 1897). The artesian wells near Belle Fourche show rates from 28 to 80 feet to one degree and the 2,965-foot flowing well at Edgemont with flow at temperature of 121 degrees indicated a rate of 39 feet to one degree, the same as two 700-foot holes at Buffalo Gap.

TEXAS.— There are many data from deep holes and wells in Texas. The 3,330-foot well at Manlin with flow temperature of 147 degrees indicates a rate of 41½ to one degree, similar to the rate at Corsicana and some other places. The 3,250-foot well at Fort Worth probably indicates a rate of 18½ feet to one degree if all the flow is from 1,127 feet The Waco wells indicate average rate of 50 feet to one degree. Big Hill in Matagordo County 23½ feet to one degree; Batson 21½ feet to one degree; Sourlake 27½ feet to one degree, the four last in the oil regions where the rate appears to be high.

UTAH.— A few observations in Milford-Beaver region indicate high rates, 12 to 24 feet to one degree.

VIRGINIA.— The investigations by Rogers in coal mines west of Richmond showed gradients of 72 to 84 feet to one degree. In the 2,130-foot hole at Fort Monroe a rate of 64 feet to one degree was found.

WASHINGTON.— Flowing wells in North Yakima Basin show rates of 25 to 36 feet to one degree. At Walla Walla a rate of 41½ feet to one degree was found.

WEST VIRGINIA.— The deepest hole in the world is on the Goff farm eight miles northeast of Clarksburg in northern West Virginia. It was 7,363 feet deep in March 1918, and a test at 7,000 feet showed temperature of 152 degrees, indicating a rate of increase of about 51 feet to one degree. In the 4,771-foot hole four miles southeast of Wheeling the temperature at 4,462 feet was 110 degrees, indicating a rate 70 to 83 feet to one degree. In the 5,236-foot hole at Chelyan near Charleston the rate is 73 feet to one degree; 2,500-foot hole near Mannington 93 feet to one degree.

WISCONSIN.— Temperatures of water from flowing wells in Wisconsin indicated rates varying from 54 to 100 feet to one degree.

WYOMING.— Three deep holes give widely different rates; Cambria 107 feet to one degree, Newcastle 21 feet to one degree and near Meteetsee 54 feet to one degree.

Consult reports of committees to investigate rate of increase of underground temperature (in British Association for the Advancement of Science, reports of meetings of 1868 to 1881, et seq., notably the 52d, 1882, pp. 72–90); Dunker, E., 'Ueber die Wärme im Innern der Erde und ihre moglichst fehlerfreie Ermittlug' (in *Zeit. für prac. Geologie*, November 1896); Jaczewski, 'Uber das thermische Regime der Erdoberflache in Zusammenhang mit den Geologischen Prozessen' (in *Verhand. der K. Russ. NELSON H. DARTON,
Geologist, United States Geological Survey.

UNDERGROUND WATERS. See WATERS, UNDERGROUND.

UNDERHILL, John, American colonist: b. Warwickshire, England, 1597; d. Oyster Bay, L. I., 1672. He served in the Netherlands and in 1625 in the Cadiz expedition, in 1630 was summoned by Winthrop to New England to train the inhabitants in martial discipline and in 1634 was chosen from Boston to the Massachusetts assembly. In the Pequot campaign of 1637 he distinguished himself as commander of the New England contingent. His account of the war, 'Newes from America' (1638), was reprinted in the 'Collections' of the Massachusetts Historical Society (3d series, Vol. VI, 1837). Underhill's mode of life and his championing of Antinomianism rendered him very unpopular in Massachusetts. Subsequently he was governor of Exeter and Dover, N. H., and held office in the colonies of New Haven. About 1643 he entered the military service of the Dutch in New York, but he was driven out of that colony in 1653 and went to Rhode Island

where he was commissioned to wage war against the Dutch in New York. Upon the fall of the New Netherlands to the English in 1664 Underhill settled in Oyster Bay, L. I., on a tract of 150 acres ceded him by the Mantinenoc Indians.

UNDERWOOD, Benjamin Franklin, American author and editor: b. New York, 6 July 1839; d. 10 Nov. 1914. At the outbreak of the Civil War he enlisted as a private in the Union army, was wounded and captured at the battle of Bull Run, and was not exchanged until 1862. He then became lieutenant and adjutant in the Rhode Island Heavy Artillery and served until the close of the war, acting in the meantime as war-correspondent for the Newport, R. I., *News*. He was engaged in lecturing for 30 years after the war and in 1870–85 he was particularly prominent as an exponent of religious "free thought." He was business manager and coeditor of the Boston *Index* in 1880–86 and in 1887 was engaged in a like capacity on the Chicago *Open Court*. He edited the *Illustrated Graphic News* in 1888, the *Philosophic Journal* in 1893–95, has written editorially for the *Free Thought Magazine* since 1893. He was secretary of the Psychical Science Congress at the Columbian Exposition in 1893 and has published 'Influence of Christianity on Civilization' (1871); 'Spencer's Synthetic Philosophy' (1891); 'Utilitarian Ethics' (1903), etc.

UNDERWOOD, Francis Henry, American author: b. Enfield, Mass., 12 Jan. 1825; d. Edinburgh, Scotland, 7 Aug. 1894. He was educated at Amherst College, studied law in Kentucky, and was admitted to the bar in 1847. He returned to Massachusetts in 1849, was appointed clerk of the State senate in 1852, and in 1854 became literary adviser of the Boston publishing house of Phillips, Sampson and Company. The establishment of *The Atlantic Monthly*, by that firm, was due to him and it was he who secured James Russell Lowell as editor-in-chief, Underwood being assistant editor. Two years later his connection with the periodical came to an end, and from 1859 to 1870 he was clerk of the Supreme Criminal Court, Boston. He subsequently devoted himself to literary work till 1885, when he was appointed to succeed Bret Harte as consul at Glasgow, and while in Scotland he lectured on American literature. His term of office expired in 1889 and he returned to the United States for a time, but in 1893 was appointed consul at Edinburgh. He was the author of 'Handbook of English Literature' (1871); 'Handbook of American Literature' (1872); 'Cloud Pictures' (1873); 'Lord of Himself,' a novel of Kentucky life (1874); 'Man Proposes,' a novel (1880); 'The True Story of the Exodus,' an abridgment of the work of Dr. Brugsch-Bey (1880); biographies of 'Longfellow' (1882), 'Lowell' (1882), and 'Whittier' (1883); 'Quabbin' (1890); 'Dr. Gray's Quest' a novel (1896). His best work is seen in 'Quabbin,' a sympathetic study of life in a small New England town two generations ago. He was endowed with a strong personality, had a wide acquaintance with books and men, possessed a fine critical sense and not a little literary power, but was to some extent lacking in constructive skill and character delineation.

UNDERWOOD, Horace Grant, pioneer missionary in Korea: b. 19 July 1859; d. 12 Oct. 1916. Born in London, he came to America at the age of 12 and was educated in the New York University and New Brunswick Theological Seminary. Arriving in Korea, under the Presbyterian Board, United States of America, in 1885, he began explorations and researches, showing an aptitude for mastering the language and an intensive energy in every sort of service to the people and rulers, from practical hygiene and education, to the counsel of royalty, while ever ardent and wise as a promoter of Christian unity, in continuous toil, from 1885 to 1915. Editor, preacher, teacher, he eschewed offers from the king of political honor and emolument. Was chairman of the board of Bible translators, from 1887 to 1911, and of the Korean Tract Society; professor of theology in the Korean Theological Seminary 1907–15; head of the Korean Educational Federations; principal of the John D. Wells Training School 1907–15, and founder of the Christian College in Seoul. Lecturer in America on Foreign Missions. At his death there were 46 Protestant Christian churches within a radius of six miles from the centre of Seoul, the capital. He was author of a Korean-English and English-Korean Dictionary (1889); 'Introduction to the Korean Spoken Language' (1890); 'The Call of Korea' (1908); 'Religions of Eastern Asia' (1910). Consult the biography by his wife, Lilias Sterling Horton, herself physician and missionary, married in Korea in 1889, and author of 'Fifteen Years Among the Topknots' (1904); 'Underwood of Korea' (1918).

UNDERWOOD, John Cox, American soldier and civil engineer: b. Georgetown, D. C., 12 Sept. 1840. He was graduated as a civil engineer at the Rensselaer Polytechnic Institute, Troy, N. Y., in 1862, and served with distinction in the Confederate army during the Civil War, reaching the rank of lieutenant-colonel. For nearly a year he was held as a prisoner at Fort Warren. In 1870–72 he was mayor of Bowling Green, Ky., and during 1866–75 served as city, county and consulting State engineer. From 1875 to 1879 he was lieutenant-governor of Kentucky. He was prominent in several secret fraternal organizations and Confederate patriotic societies; and in 1896 was chosen superintendent and secretary of the Confederate Memorial Association.

UNDERWOOD, Lucien Marcus, American educator and botanist: b. New Woodstock, N. Y., 26 Oct. 1853; d. Redding, Conn., 16 Nov. 1907. He graduated from Syracuse University in 1877 and was professor of botany there 1883–91. From 1896 he was professor of botany at Columbia. He published 'Systematic Plant Record' (1881); 'Our Native Ferns and How to Study Them' (1881–1901); 'North American Hepaticæ' (1884); 'Our Native Ferns and Their Allies' (1888); 'Hepaticæ Americanæ' (1887–93); 'Moulds, Mildews and Mushrooms' (1889). Consult Bonker, H. J. (ed.), 'Underwood Families of America' (1913).

UNDERWOOD, Oscar Wilder, American legislator: b. Louisville, Ky., 6 May 1862. Educated at the University of Virginia he was admitted to the bar in 1884 and practised in Birmingham. He was chairman of the Democratic

committee that adopted the present constitution of the State, was member of Congress (1895–1915) and was elected United States senator (1915–21). He is a prominent leader of the Democratic party and its chief tariff expert. He was a popular candidate for the presidential nomination in 1912.

UNDERWRITER, one who insures, or makes a business of negotiating contracts of insurance. The term is particularly employed in connection with marine insurance. More recently it has come to be used in relation to certain modern financial conditions. Upon the organization of a corporation to absorb several companies, it is customary to raise a sum of money to be employed either as a working capital or for the purchase of such stock in the companies as original holders are unwilling to exchange for the new securities of the corporation. The one employed in raising this sum is styled the underwriter. See INSURANCE; INSURANCE, LIFE, IN AMERICA; INSURANCE, MARINE; FIRE INSURANCE IN AMERICA; UNDERWRITING.

UNDERWRITING, in finance, a method of floating the bonds and securities of large corporations by means of fiscal agents or syndicates. The general rule governing the underwriting of new securities is that the syndicates shall receive a commission of 5 per cent on the value of the securities underwritten. As an illustration take a railroad issuing $50,000,000 of bonds. The railroad, it may be presumed, is of good standing, and the security excellent. The company prefers, instead of securing a high premium on the bonds, to save in the annual interest charges. So it issues a 3½ per cent bond, with the probability that it will sell at par, or perhaps higher. The underwriters agree to take the entire issue, say at 98, but it charges a commission of 5 per cent, or about $2,500,000, for labor, expense and risk attending the operation. The railroad is now secure. It is assured of the money it needs for which it has, indeed, paid a liberal discount, but no more liberal, proportionately, than would be required in procuring a modest loan in the ordinary market channels. The syndicate must now sell the bonds. If there is an active investment demand, it may be able to accomplish this at once, at a considerable advance over the underwritten price of 98. Suppose it sells at 102, the syndicate would then reap a profit of 4 per cent, or $2,000,000 in addition to the commission of $2,500,000, less, however, the cost of advertising, wages, attorneys' fees and other incidentals. But if the demand were not as great as had been anticipated, the syndicate might find itself with millions of dollars of securities on its hands, for which it must pay, but for which there is no adequate market.

UNDINE (1811), the first notable writing of La Motte-Fouqué, is a classic of romantic daintiness. "The fragrance of poetry and the songs of the nightingales," said Heine, "were put into words by Fouqué and he called it Undine." The tale's prosaic framework is this: Knight Huldbrand finds at a fisher's hut, Undine, a foundling water sprite, who to win herself a soul through marriage has taken human shape, while still warned, guarded and served by her native element, embodied in her uncle, Kühleborn. Undine marries Huldbrand, gains a soul, but must lose life if she cannot hold him true to her love. Her nature is transformed to a tenderness that embraces even her companion and rival Bertalda, discovered to be the fisherfolk's daughter. Kühleborn, warning, threatening, is repelled. Undine loves too fondly, till at last Huldbrand's vagrant affections break the spell, and Undine melts from his presence, but not from his life. For she has kept her soul and, when warnings cannot keep him from Bertalda, returns on his wedding eve to draw away his life in a kiss and, as a perennial spring, to clasp his grave in her embrace. The tale, as a legend of the Ritter von Staufenberg, dates from 1400. It was retold by Fischart and mystically interpreted by Paracelsus in his 'Liber de Nymphis' (1590). As poetized by Fouqué it won immediate popularity, was made subject of three operas, widely translated and illustrated by noted artists. Consult Pfeiffer, W., 'Über Fouqué's Undine' (1903).

BENJAMIN W. WELLS.

UNDISCOVERED COUNTRY, The, a story by W. D. Howells, published in 1880. The central figure, Dr. Boynton, an enthusiastic spiritualist, is an admirable study of an honest charlatan. He has become a monomaniac on the subject of spiritualistic manifestations and, branded as a cheat, with his daughter seeks refuge in a community of Shakers, whose quaint and kindly ways are portrayed with a loving pen.

UNDUE INFLUENCE, a legal term of frequent use in testamentary suits, and sometimes in cases of contested elections. Undue influence in the making of a will is exerted when the testator is so unnaturally influenced that he makes his will in favor of some one other than his natural heirs,—undue influence being oftenest charged when the testator's mind was infirm or weakened by illness and his will was made while he was under the supervision of the outside beneficiary. Where undue influence is proved the court will set a will aside or allow compensation. See WILL.

In voting, undue influence consists of force, violence, restraint, threat or intimidation practised at the polls to influence votes to the way of thinking of the person making such demonstration. When proved it vitiates the result to the polling and lays the perpetrator open to penal action, with severe punishment. The burden of proof rests on the party making a charge of undue influence. See CORRUPT PRACTICES ACTS.

UNDULATORY THEORY OF LIGHT, or WAVE THEORY OF LIGHT, the theory which accounts for the phenomena of light and radiant heat, by interpreting them as the results of vibratory movements or undulations, in an all-pervading medium called the "ether" (q.v.). There are many optical phenomena which admit of a ready mathematical explanation in this manner, without making any very definite assumptions concerning the nature of the ether, or the kinds of motion that occur in it. In order to explain the phenomena of polarization, however, it is necessary to assume that when a light-ray passes through the ether, the ether is disturbed in such a manner that its particles oscillate back and forth in paths

which are perpendicular to the direction in which the light-ray is traveling. In this respect the motion of the ether is very different from that which prevails in air when a wave of sound traverses that medium; the motions of the air particles in the case of a sound-wave being to and fro along lines that are parallel to the direction in which the wave is progressing. The motion of the ether when a light-ray traverses it is supposed, in fact, to be very similar to the motion by which a vibratory disturbance is propagated from one part of an incompressible elastic solid to another part; and for this reason the undulatory theory of light is often called the "elastic-solid" theory.

Christian Huyghens was the first to give the undulatory theory of light a definite form, and the origin of that theory may fairly be said to date from a paper written by him for the French Academy of Sciences, in 1678. Sir Isaac Newton was well aware of the possibility of accounting for many of the phenomena of light, by assuming that light consists of a kind of wave-motion in an all-pervading ether; but he objected to the undulatory theory, because he could not understand how a body could cast a sharp shadow if that theory were correct. He was of the opinion that the waves would necessarily sweep around obstacles, and close in behind them in such a way as to render sharp shadows impossible. Newton, therefore, adopted the alternative "corpuscular theory," which teaches that light consists of storms of tiny material particles, or "corpuscles," which tend, by reason of their inertia, to travel in straight lines. He developed this theory with characteristic power and ingenuity, so that physicists were long divided between his teachings and those of Huyghens. In 1801, Dr. Thomas Young, an English physicist, solved the difficulty which led Newton to reject the undulatory theory; for he showed that when the dimensions of an opaque object are very great in comparison with the wave-length of light, the light-waves which fall upon the object are prevented from sweeping around and closing up behind it, by means of the phenomenon known as "interference"; those waves which tend to pass around behind such an obstruction becoming compounded together in such a manner as to neutralize one another. Young's discovery stimulated investigation so that within the next 20 years great advances were made in the development of the undulatory theory. Young and Fresnel, for example, explained the phenomena of polarization, and Fresnel developed his beautiful theory of the optical phenomena manifested by crystals. The objections raised by Newton had been entirely disposed of, and the undulatory theory had been placed upon an apparently firm foundation. Moreover, there are two things about the corpuscular theory which appeared to be absolutely fatal to it. The first is, that it does not lend itself readily to the explanation of interference. It is easy to understand that two waves in the ether may come together so as to neutralize each other; for an analogous phenomenon may be seen any day at the seashore, in ocean waves. It is not at all easy to understand, however, how two streams of light-producing corpuscles can produce darkness, when either stream alone will produce light. Another even more fatal objection to the corpuscular theory was, that this theory cannot explain refraction unless it is admitted that light travels faster in a dense medium than it does in a rarer one, while the undulatory theory requires that the light shall move faster in the rarer medium. Fizeau and Foucault proved by direct experiment that light travels faster in air than it does in water; and hence it was considered that they had proved that the corpuscular theory is not correct.

About the middle of the 19th century Michael Faraday published his experimental researches on electricity and magnetism; and although these did not deal particularly with light, it happened that they had a most important ultimate influence upon our views as to its nature. Maxwell, in studying Faraday's work and endeavoring to reduce his experimental results to a consistent mathematical theory, conceived the idea that light may be merely a periodic or vibratory *electrical* disturbance in the ether. Upon working out this idea in detail, Maxwell found that the new theory is free from many of the objections that had developed in connection with the older elastic-solid theory; and the "electro-magnetic theory" of Maxwell is now held by nearly all physicists, in preference to the older undulatory theory. The difference between the two is somewhat as follows: Maxwell agrees that light is some sort of a periodical disturbance in some sort of an ether, and he also agrees that the displacements that occur as the wave progresses are perpendicular to the direction in which the wave travels; but he teaches that these displacements are not analogous to those that are produced in an elastic solid when that solid is deformed. He considers that they are of an electrical nature, and that we must learn about them, not by observing the behavior of elastic bodies under stress, but by observing the phenomena exhibited by electrified bodies. In one sense, therefore, Maxwell's theory may still be regarded as a form of the undulatory theory; but the waves that are contemplated by it are electrical in nature, and are not strictly analogous to the waves in an incompressible elastic solid. See ETHER; LIGHT; RADIATION; RADIOACTIVITY; X-RAY.

ALLAN D. RISTEEN.

UNEMPLOYMENT. In the sciences of economics and sociology the term unemployment refers to an industrial condition in which large numbers of workers are without gainful occupation. No doubt in feudal times the working classes found during trade depression, war periods and other cataclysms periods of inactivity leading to poverty and even hunger. But in those days it was not a cry issuing from hungering masses closely congregated as at present. In the early days of the artisan manufacturing units consisted of small individual "shops" where work was performed by apprentices and journeymen artisans mostly. And when the master craftsman had filled all orders and had no longer work for all, the journeyman went on his way to the next village or city seeking another job. The condition was general and provided for. The workman had his lodging-house in every town or village where, at small cost or free, he obtained board and lodging till he had canvassed the trade and ob-

tained his job or left for the next settlement. His "papers" showed the signature of his former employer as proof of his good standing and he was aided in his quest for work by the state. With the growth of the cities, and consequently of the industries supplying them, manufacturing establishments grew into factories where the larger units could use more economy in methods besides producing in larger quantities at reduced cost. It was the opening of that stage of civilization known as industrialism. And with these ever growing aggregates of manufacturing industries forming themselves into trade centres with their great populations of "hands" or operatives was brought into being the hideous feature we know as "unemployment." Its paradoxical phenomenon is conspicuous in the fact that with the growth and increasing prosperity of the industries we find shoe factories closed in the midst of crowds of shoeless able workers whose presence forces on one's knowledge that the need or demand for footgear is great; the huge clothing factories shut down their operations while many thousands of willing workers stand outside shivering from lack of apparel with which to protect themselves against the elements.

Problem.— In a statement of the features of the subject of unemployment must not be omitted notice of the fact that large numbers of healthy and willing workers unable to find employment carries with it the direct consequence of indignation and "unrest" among the populace generally of wage-earners, a disease of the body politic that at any time is a breeder of anarchists and revolution. Again another degrading influence of unemployment is its demoralization of the suffering working classes who lapse easily into beggary and morally and physically deteriorate so as to become *unemployable*, as inefficient and unreliable. Like most diseases unemployment in an industry is infectious. The enforced idleness of these thousands affects other thousands in other trades as the penniless state of numerous members of a community forbids demand and consumption of goods produced by its other members, and the sales of other commodities being reduced causes other factories to be closed down. And thus the entire chain of industry from factory to retailer, consumer, capitalist, banker, etc., is drawn, link by link, into the commercial vortex of panic.

Causes.— The direct and primary cause of the "shut-down" of factories which produce unemployment on a large scale is one of supply and demand, generally, depression of trade, *overproduction* (usually meaning enforced reduction of consumption, an outcome of trade depression). Factors also leading to reduced demand are: changing fashions, overspeculation, hoarding of capital caused by commercial fears, etc. War and panic often bring about unemployment in its worst degree. In a less degree new inventions, changes in national policy (prohibition will close up breweries and distilleries, besides saloons, etc.), excessive immigration, bad labor laws, labor disputes. Other more or less potent factors are: lack of material, weather, etc. Causes within the industry itself are numerous such as: "seasonal" employment with its fluctuations in consumption, child labor, additions to the forces by female operation, *casual* employment as that of longshoremen and stevedores, coal passers, all dependent on the arrival of ships in the port. The causes of unemployment are legion and many are insidiously invisible. Experts on the subject declare *casual* employment works with demoralizing effect on the wage-earners, creating discontent and inefficiency from the periods of idleness. On a smaller but more chronic scale we have numerous unemployed among the aged, debilitated, defectives, vagrants, etc.

Statistics.— In the United States there is not even a *system* by which to get at the statistics of the unemployed as was painfully evidenced during the great distress of 1914, when so many philanthropically inclined desired *facts* as to the extent of the far spread misery and want. Unemployment has not been considered sufficiently important to build up an organization or gathering the data of distress from period to period. American statistics on unemployment are limited to several "investigations" set in operation at different times by missions, lodging houses, bread lines, relief organizations and other heterogeneous agencies. The 1900 Federal census tells us 22.3 per cent of persons having gainful occupations were out of work some time during the year and more than 2,600,000 men and about 500,000 women were out of work seven months or more. The 'Report of the Massachusetts Board to Investigate the Subject of Unemployment' (1895) contains some statistics. The Federal Bureau of Labor made an investigation in 1901 as to the cost of living among 25,440 families of the working classes and those with salaries of $1,200 or less, and discovered 49.81 per cent of the heads of families were idle part of the year. The Geological Survey in its report on mining conditions from 1890 to 1910 shows 22 to 43 per cent of the miners' time was lost annually in the bitumenous region and the anthracite miners lost 23 to 50 per cent in other years than 1902 when the great strike was active. The Wainwright Commission in New York State in 1909 investigating employers' liabilities and allied matters found: "There were no statistics available from which to compute the actual number of those out of work," but they estimated at least 3 per cent out of work in the State's industries of those regularly employed and 8 to 10 per cent in winter. This rate increased to from 15 to 40 per cent in 1908 during the business depression. Of organized labor, where some systematic methods of obtaining employment for its members prevail, the New York State Department of Labor collected monthly the reports of the unions from 1901 to 1911, which showed an average of 14,146 unemployed each month out of an average membership of 99,069, or 18.1 per cent. This is skilled labor. New York State Commissioner of Labor found out of 600,000 organized wage-earners 101,000 idle (16.1 per cent of men) in 300 trades or branches between September 1912 and September 1913 (a bad year for labor), and growing to 38.8 per cent on 31 December 1913. Of this 92 per cent of idleness was due to lack of work and 2 per cent due to labor disputes. While the deplorable statistics given above apply to New York State, New York City had the still higher figure, ending December 1913, of 45.5 per cent with over 90 per cent of the clothing trades of this city idle and two-thirds of the union men members of the building trade. The industries themselves have no records or particulars of unemployment. In this

same stray manner the temporarily organized appointees under the Federal Industrial Relations Commission, in 1914, sent a sheet of eight questions to the chiefs of police of the cities of the United States to get at the underlying causes of industrial unrest, four of which questions concerned the unemployed in each city. It was unaccompanied by any instructions as to a system of investigation, and from this and other causes the figures forthcoming are absolutely unreliable. Women were excluded from the inquiry and we have over 8,000,000 female wage-earners; political influence on the replies suppressed or "softened down" facts unquestionable in some locations. With the utter lack of reliable statistics in this country we are liable to look to Europe for such figures of unemployment; as this industrial disease has been more malignant in the old country greater research and more remedies are discoverable there. But as to whether we can utilize such foreign statistics as a measure on which to base our activity here or whether to adopt such remedies as may have proven efficacious in France, England or Germany, we are in doubt. Whether they would prove available in the United States labor field is dubious, surrounding conditions being so very different in many respects.

Relief and Remedy.— The past World War has proven that labor can be mobilized by our government, and such an experience might lead us to suppose that this last great disaster might be the means of opening our eyes to an effective method of treatment of this economic disease of unemployment by the Federal government. The Teutonic attempt at world invasion should be accepted as an eye-opener to us that our deficiencies in politics and economics are so dangerous as to render our very stability as a republic doubtful. Anarchism and other features we now call "unrest" of the laboring classes are best (and probably only) to be fought successfully with a perfectioning of our industrial system and one that will eliminate unemployment. The war has given us both the opportunity and vision of the necessity of industrial reform. The nation must come to a decision that the question of unemployment is one of the great national issues and should be treated by Federal and State governments as one of the foremost problems and one of the permanent, not emergency, official duties due its people. The national effort to find employment for the returning regiments of the American Expeditionary Forces has brought us the hitherto lacking experience of handling that branch of the labor problem. Whether we shall gain from the experience permanent advantage the future alone can tell. As to mitigating methods against the evil many of the advanced students of the problem assert that teaching the artisan to be expert in more than one line of manipulation, so as to take up vacancies elsewhere when the operations he performs have no demand, would reduce the ranks of the unemployed to a considerable extent. There are many agencies fighting to reduce the number of sufferers from unemployment of which space permits mention of but a few. Some of these give their services free, others charge a nominal fee to veil the appearance of charity. Like the professed "intelligence offices" they spend a large part of their endeavor in locating vacancies in the industries. There are numerous public employment bureaus. Forty-six States have had laws passed providing free employment bureaus. Municipal bureaus of independent origin and operation are established in many United States cities. The municipal lodging houses do their small quota of placing their distressed lodgers in service, and the New York social service bureaus attempt to organize the units into one whole of enlarged usefulness. In 1914 the Bureau of Immigration of the United States Department of Labor started 38 branch offices in different sections through which much usefulness may result.

As to "relief" agencies of philanthropic effort, the danger lies in the fact of their tendency to reduce the moral status of the assisted workers. This may occur by allowing the form of administration of assistance to be openly "charity" work or by creating in the recipients habits of idleness, in both of which cases the agency is creating mendicants or dependents instead of maintaining the needful feeling of independence and the desire for active and gainful occupation. The general theory is, therefore, that philanthropic assistance shall be exerted only in behalf of those incapable of strenuous labor, such as the aged, debilitated, wounded, etc. A class of recent assistance to employment is represented in the Jewish Agricultural Aid Society and the Industrial Removal Office of New York City. But their function is mainly to place freshly-arrived Jewish immigrants in agricultural occupations and thereby avoid these from becoming additional competitors in this already overcrowded city. The plan of activity practised by the agencies of the churches, missions or parish houses have been usually on a pseudo self-supporting basis of fees. Of a similar character is the employment department of the Salvation Army and Volunteers of America, covering a large sphere of usefulness in both skilled and unskilled ranks of labor, where work accompanies the assistance as a reciprocal. There is also the Inter-Church Committee on Unemployment of the New York City Federation of Churches with activities of the broader scope. The Y. M. C. A., the Y. W. C. A., etc., employment bureaus carry out their part of the program for clerical and business employees unemployed. The National Employment Exchange *places* quite a number of workers of all kinds and charges fees. One expert at least is of opinion that the quantity of small employment agencies of the free order is too large and the effort should be diverted to large clearing houses of labor closely in co-operation with organized labor and organized business, all "relief" or "welfare" work being restricted to emergency and disability cases. Civic organizations recently have taken up this important problem of unemployment in other branches of activity than the locating of work for unemployed labor. Of such are The American Association of Labor Legislation, the Committee for Immigrants in America, whose work is the stimulation of labor legislation, propagation of public interest in the unemployment problem, etc. The defect of all the above agencies is lack of combined organization, being strictly local or independent in action.

A general survey of the situation would

make it appear that logically there are two main points of attack in the unemployment problem. (1) The temporary *amelioration* of a prevailing condition (relief on civil, State, Federal or philanthropical lines); (2) the *eradication* of the condition, preferably by Federal organization (it is a *national* disease). But the latter course calls for the co-operation of the industries themselves. A commencement of the United States intervention in this great national issue was the establishment of the Department of Labor with its secretary a member of the Cabinet in the United States government, created 1913. An early act was to establish 18 zones "for the purpose of facilitating the distributing of farm labor in the United States, with headquarters in the large cities. Several annual meetings of the International Conference on Unemployment have brought forth theories and useful discussion with interchange of views, and we must hope that there will arrive a decision for some definite course to pursue for the extirpation of this international evil. From the National Industrial Conference held at Washington, D. C., 1919, good results must be hoped for, as it brings capital and labor into direct negotiation and both armies of production have now been trained to the knowledge that *singly* their efforts at profit-making and producing are nugatory.

Practically all the above enumerated agencies are factors for *relief*, for the allocation of unemployed labor, not for the eradicating of unemployment, for remedy, not cure, which, after all, is the main part of the problem for solution. These existing, mostly disconnected, sources of relief do not increase the volume of work nor regulate the industries from which work emanates. Experimental efforts are being brought to bear more or less in this direction. For creating work, charitable associations have established emergency industries, such as woodyards; sewing-rooms for women; some cities have established road-building systems to afford extra work (including the quarrying and crushing of the stone for same) and other public works. This, however, is closely on a line with the snow-removal winter work of the cities. But plans for the reduction of the causes of unemployment in the industries, the equalizing of labor demand for the *seasonal* industries, for instance, has been of a strictly individual and sporadic nature. The nearest approach to this solution is, probably, the recent attempt of a large automobile concern to work its maximum output during the winter months and make its slack season during the summer, thus releasing its operatives for work on the harvesting. Another method recently employed by several industries is to make a reduction of the hours of labor so as to spread the work over a larger number of employees and thus avoid the throwing out of work so many operatives. Some of the larger unions pay their members something during their unemployment out of their assessments, and the labor unions in general look after obtaining work for their members — this is the fruit of *organization*, that mainspring from which in the end, many experts tell us, must arise the eradication of unemployment. This matter of organization, from present aspects, is likely to take some form of "socialization" of the interests of capital and labor in the different industrial establishments, a closer relation between employer and employee, as is being quite forcibly done in England since the World War. The Commission on Industrial Relations and other recent activities tend to show that, at least, this nation is awaking to the fact of the immensity of the problem from a national as well as social need.

Unemployment insurance has taken rapid strides, even becoming a state measure among several European nations, and has had much discussion in this country. Its purpose is, however, the lessening of distress of the unemployed and is no cure for the disease. The Ghent System holds a high place in this class of labor reform. The National Insurance Act (1911) in England followed the failure of the working of the Unemployed Workmen Act, and was a move in the direction of providing against too great distress of the unemployed, but its small weekly dole does nothing much toward reducing non-employment. Germany has shown the path to a systematic plan of avoiding the non-employment evil with its government free employment offices and bureaus for all classes of labor and its trade committees formed of employers and employees in equal numbers, besides its citizens' committees in charge of the bureaus. Its free shelters (*Herberge*) or hotels for journeyman artisans is an ancient institution. These systems are all, possibly, unadaptable to American conditions, without modification, but they lay down methods of control that may be shaped into such form as to be practicable in the United States. The amount of public discussion of this enormously important subject which has found its way into print may be conjectured by the fact that 'Selected Articles on Unemployment,' compiled by Julia E. Johnsen (New York 1915), has a bibliography of 22 pages.

UNGAVA, ŭng-gā'va, Canada formerly, a northeastern territory formed in 1895, in the Labrador peninsula since 1912 the Territory of New Quebec. It is bounded on the north by Hudson Strait, west by Hudson Bay and James

Bay, south by Quebec, and east by the Atlantic. Area, 351,780 square miles. Ungava Bay, in the north of the district, opens into Hudson Strait. Pop. 14,000 of whom 8,000 are whites, 2,000 Eskimo and the remainder Indians. Consult 'Reports on Ungava, recently Added to the Province of Quebec, under the name of New Quebec' (Quebec 1915).

UNGER, ŭng'ĕr, **Frederic William,** American journalist: b. Philadelphia, 25 Jan. 1875. He was educated at the Eastburn Academy, Philadelphia, and after studying for the ministry and for the bar, abandoned both for journalism. He was attached to Lord Roberts' headquarters as staff correspondent for the London *Times* during the South African War. He published, 'With Bobs and Kruger' (1901).

UNGULATA, a great and heterogeneous group of hoofed mammals which first appeared in the Eocene period as small marsh-dwelling forms scarcely distinguishable from the contemporaneous ancestors of the *Carnivora,* but which early became differentiated into several quite distinct series that have continued to diverge until in the living fauna they terminate in quite isolated groups. Under these circumstances it is not surprising that the opinions of zoologists differ greatly concerning the classification of these animals. Without considering the changes in classification that have followed increased knowledge of the living forms, it may be said that if the latter alone were considered they would fall naturally into three distinct groups; one typified by the horse, ox, pig, etc., another by the elephant, and the third by the coney (*Hyrax*). But with the great palæontological discoveries of recent years, especially in the Eocene of Wyoming and other Western States, and in the later formations of Patagonia, not only have these groups been connected by annectent forms, but several totally new types have been found, and generalized ungulates have been shown to intergrade with the *Carnivora* on the one hand and with the *Rodentia Quadrumana* on the other. By some zoologists, as Cope, each of these principal groups, or radiating descent-series, has been given a distinct ordinal name. Others have grouped all together as a single order, with numerous subdivisions. As the latter arrangement is best adapted to the needs of the present article it is here followed.

In this broad sense the *Ungulata* have on each foot from one to five digits, terminated by broad, blunt nails or hoofs. With a very few exceptions among extinct primitive forms they are digitigrade and many of them walk on the very tips of the toes. The scaphoid and lunar bones of the wrist are always distinct. Well-marked milk and permanent dentitions are always developed, and with a few exceptions these animals are strictly terrestrial and herbivorous. Evolution in this group has particularly affected the feet and teeth, with the other digestive organs. Correlated with the replacing of marshy forests by dry, grassy plains these animals increased in size and developed greater speed in running by a reduction in the number of digits from five to two or one, by the union of certain bones of the foot and lower leg, and by a change in the position of the carpal and tarsal bones, so that they alternate and interlock. As the soft succulent vegetation of the swamps gave way to the wiry grasses of the plains the teeth gradually changed from a tuberculate low-crowned form to one with crescentic and then complexly-folded enamel ridges, and a high persistently growing crown. Although similar changes have been traced in many families, they are shown in greatest perfection in the horses, where every step in the evolution from the four-toed, low-tooth-crowned *Orohippus* of the Eocene, with well-developed ulna and fibula, to the one-toed, complexly high-crowned modern *Equus* with the greatly reduced ulna and fibula completely ankylosed with the radius and tibia respectively. See HORSE, EVOLUTION OF.

A subdivision of all the *Ungulata* into *Ungulata Vera,* or true ungulates, and *Subungulata* is generally followed, though this, as indeed every sharp subdivision of the ungulates, is obscured by known fossil species. The *Subungulata* is a rather heterogeneous assemblage of the more primitive forms, in which the bones of the carpus and tarsus are not at all or only partially interlocking, the toes often five in number, and the feet sometimes subplantigrade. Some of the extinct forms have well-developed clavicles. In the living species the mammary glands are, at least in part, situated on the breast, and the placenta forms a zone or broad band. Besides the many remarkable extinct groups placed by Cope in the orders *Taxeopoda* (*Condylarthra*), *Toxodontia* and *Amblypoda,* the *Hyracoidea* and *Proboscidea,* represented in the modern fauna by *Hyrax* and the elephants, belong here.

The *Hyracoidea* and family *Hyracidæ* comprise only a few species of small rodent-like animals of the genera *Hyrax* or *Procavia* and *Dendrohyrax,* inhabiting Africa, Syria and Arabia. They present certain resemblances to the elephants on the one hand, and to the rhinoceroses on the other, but in most respects are quite isolated. The *Hyrax syriacus* is believed to be the "coney" of Scripture. The front feet have four and the hind feet three toes, enclosed in hoof-like nails. No clavicles exist. The nose and ears are short, and the tail is rudimentary. No canine teeth exist, and the incisor teeth grow from permanent pulps like those of rodents. The placenta is zonary and deciduate, and there are six teats. The intestine is remarkable in having a large sacculated and a pair of small conical cæca. These animals live in burrows in rocky mountainous districts, and are known as "rock-rabbits" or "dassies," while the species of *Dendrohyrax* are arboreal and live in hollows of trees.

The elephants (q.v.), although usually placed in a distinct order of mammals — *Proboscidea,* are related to the other ungulates through the *Hyracoidea* and *Amblypoda.* Each foot possesses five toes. There are no clavicles. The nose is prolonged to form a flexible proboscis, at the extremity at which the nostrils open. The testes are abdominal throughout life. The breasts are pectoral in position, and the placenta is non-deciduate and zonary. The canine teeth are wholly wanting, and the molars are few in number and are ridged or tuberculate on their crowns, very high and complex in structure in the specialized forms and appear in the jaws from behind, one at a time. The upper incisors

grow from persistent pulps and form tusks. No lower incisors are developed in the elephants but existed in *Dinotherium* and some species of *Mastodon*. The extinct *Proboscidea* are of exceptional interest. The various species of mammoth, mastodon, etc., which belong to the family *Elephantidæ*, possessed enormous tusks curved nearly into a circle in the former, straight in the latter, and their remains are associated with those of early man. The *Dinotheriidæ*, remains of which are found in the Pliocene formation, possessed simple tuberculate molars and the lower incisors were greatly enlarged to form downwardly-turned tusks, on which account these animals were formerly associated with the walruses.

The *Ungulata Vera* (or *Diplarthra* of Cope) include the great majority of living ungulates, most of which are highly specialized in respect to foot and tooth structure. They never have more than four fully-developed toes on each foot; these toes being provided with hoofs, and are never plantigrade. No clavicles or collar-bones are developed, though transitory ones sometimes occur during fœtal life. The placenta, which is either diffuse or cotyledonary, is of the non-deciduate type. The molar teeth have broad crowns and vary in the different families. The mammæ or milk-glands of the female are usually few in number and placed in the groin; or more numerous and abdominal. The intestine is very usually provided with a large cæcum; and the stomach may be complex. Regarding the classification, a primary character is found in the number of the toes, with which many other characters are correlated.

The section *Perissodactyla* includes those forms in which the toes are usually present in an odd number (solid-hoofed). The third or middle toe tends to predominate, while in the *Artiodactyla* the number is even and the second and third predominate (split-hoofed). The dorso-lumbar vertebræ (that is, the vertebræ of the back and loins collectively) do not number less than 22. The dentition varies, but the premolars and molars are always similarly formed. The third digit or toe of each foot is symmetrical by itself, that is, does not form a pair with its neighboring digit. The thigh or femur bears a third trochanter. The stomach is of simple character, and the cæcum of very large size. The teats are inguinal in position and the placenta is diffuse. If horns are developed they belong merely to the epidermis, are not supported by a bony core, and are never paired in living forms. Where two horns exist (as in some rhinoceroses) the second is situated behind the first. Belonging to the perissodactylate *Ungulata*, besides many extinct Teritary families, are three living ones typified by the tapirs, rhinoceroses and horses (qq.v.). The group is declining.

The *Artiodactyla*, or "even-toed" ungulates, are distinguished by the presence of either two or four toes, the third toe of each foot forming a symmetrical pair with the fourth. The premolar teeth, whatever their character, are always simpler than the molars. When horns are developed they nearly always exist in pairs, and are supported on bony "cores." The stomach is very complex in the ruminating forms, and the cæcum is small. The dorso-lumbar vertebræ number 19, and the femur wants a third trochanter. Unlike the *Perissodactyla* the *Artiodactyla* are a dominant group and, while in the early Tertiary times they were surpassed by the former in number and variety, they have steadily progressed as the latter have declined, and to-day are represented by about one-third of the known families, very numerous genera and species and often vast numbers of individuals. The living families are arranged under the sections *Suina*, or pig-like *Artiodactyla*, *Tylopoda*, or camel-like *Artiodactyla*, *Tragulina*, the chevrotains, and *Pecora* or ruminants.

UNICORN, a fabulous animal, described in ancient accounts as a native of India, with the body of a horse but of larger size, and with one horn of one and one-half to two cubits in length on its forehead, perfectly straight, with a white base, black middle and red tip. The unicorn was adopted as a supporter of the royal Scottish arms, from which it has been introduced as the left supporter of the British arms, and has in this form been imported into India. Consult Brown, Robert, 'The Unicorn' (London 1881) and Gould, Charles, 'Mythical Monsters' (ib. 1886).

UNICORN-FISH. See File-fishes.

UNICORN PLANT, one of the popular names of plants of the genus *Martynia*, glandular, pubescent and fetid herbs, natives of America. They have irregular funnel form corollas, with oblique tubes, and limbs which are slightly two-lipped. The flowers are velvety, yellowish-white and purple-mottled, and borne in racemes on a decumbent stem possibly two feet long in the devil's horns (*M. louisiana*), common in the southwestern United States, and occasionally escaped from gardens. The leaves vary from ovate to orbicular, sometimes undulate at the edges, and the fruits are four-celled, four to five inches long, oblong, and prolonged into a curved point much longer than the body. At maturity the rather fleshy outer green layer of the fruit disappears, and leaves the woody part of the pods, which ultimately splits into two valves, that are very tough and black, and sometimes as much as 13 inches long. These tapering horns are moistened and split by the Indian women of the Southwest, who weave them into their baskets, as the black element necessary in their color-scheme of decoration. The plant itself often serves as a motif for the design.

UNICORN-ROOT, a graceful smooth plant (*Chamælirium luteum*) of the bunch-flower family. It has a tuft of radical spatulate foliage and narrow stem-leaves. The flowers are

small and white, with a perianth of six segments, and are dicœcious, in long racemes. The staminate racemes, nodding at first, eventually stand straight; fertile ones are always erect. The fertile plants are sometimes three feet high. The tuberous rootstocks are bitter, and an infusion of them is a popular tonic and anthelmintic, and is said to be a large ingredient of certain patent medicines. One of the industries of the mountaineers of the southern Alleghanies is that of digging these roots. This *Chamælirium* is also known as devil's bit, or blazing star. The latter name being more generally and correctly applied to the stargrass (*Aletris farinosa*), which is a similar plant, having a bitter tuberous rhizome.

UNIFORMITARIANISM, Huxley's name for the Lyellian doctrine of uniformity of geologic processes and results in all ages of the earth's history. In other words this doctrine teaches that the forces operative upon and within the earth to-day were active in former geologic times, and produced the same results, and to them alone are due the structural features of the earth and not to catastrophic revolutions. See HUTTONIAN THEORY.

UNIFORMITY, Act of, in English Church history, the acts 13 and 14 Charles II, designed to regulate the terms of membership in the Church of England and in the colleges of the universities of Oxford and Cambridge. Both the Anglican (or Episcopal) and the Presbyterian parties had desired that their respective belief should be that of the established church, and Charles Stuart, who, as a step toward obtaining his father's throne, wished to stand well with both parties, promised, while still in exile at Breda, to use his influence to bring about a certain measure of comprehension. But the Parliament, which was overwhelmingly Anglican, was in no mood to favor such a scheme, and the Act of Uniformity which was passed required the clergy to sign the Thirty-nine Articles and to use the Book of Common Prayer. The enforcement of these regulations wrought the exclusion or the secession from the established church of 2,000 ministers and laid the foundation of modern dissent. Among the provisions of the Act of Uniformity was one which made actual receiving of the communion of the Anglican Church a condition precedent to the holding of public offices; this condition was abolished by the act 9 George IV, ch. 17; and in 1829 the Test Act of 1672, a supplement to the Uniformity Act, was repealed; that act excluded Roman Catholics from public offices. In 1871 the University Tests Act abolished subscription to the articles, all declarations or oaths respecting religious belief, and all compulsory attendance at public worship in the universities.

UNIFORMS, Military and Naval, special costumes used in an army or a navy. While badges of identification have been known at all epochs, and while the followers of a lord often wore the livery of their master, the use of a uniform costume by large bodies of men was unknown until the modern era of large standing armies. The first advance beyond temporary badges was the use of a colored scarf to identify the various brigades of the Swedish army under Gustavus Adolphus. This device spread rapidly. The danger of the use of such simple devices by an enemy soon led — first in France and soon after in England — to the adoption of a more or less definite uniform. The "New Model" of Cromwell was clothed in a costume essentially that of the civilians of its time but of the uniform color of red with gray breeches and with special regimental facings. The armor which was originally worn over the uniform disappeared throughout Europe early in the 18th century and the use of the uniform was established to about the same extent as it prevails to-dav.

The military costume, like the civil, changed little in general outlines till the end of the 18th century. The original broad-brimmed felt hat was modified into the cocked hat, the breeches and coat lost their original fullness and the uniform became what is familiar to us in pictures of the American Revolution. Garments apparently less adapted than those of the middle of the 18th century to the active business of fighting can scarcely be imagined, yet after all they were in precise accord with the stiff, formal, drill-master-like spirit of the close-order fighting of the day. The stock and collar came into use and much that previously played a useful part in the uniform — cuffs, lapels, etc. — was reduced to a dummy form which served for ornament alone. Various forms of headgear worn by irregular troops from eastern Europe became stiffened and formalized into shapes which partly ousted the cocked hat, and are even yet in use. Among these were the busby, the fur grenadier cap and the mitre-cap of the Prussians, all descended from a conical cap edged with fur; the stiff leather shako — which has given rise to most of the military headgear of the world to-day — and the square-topped czapka or lancer cap, which has shrunk from a crude leather cap to a complicated device mimicking to a greater or less extent the German pickelhaube.

Toward the end of the 18th century the ample tailed coat began to shrink into the coatee, of a size scarcely greater than that of the tunic or blouse of the present day. This made necessary the introduction of a new article of military apparel — the overcoat. The breeches and white gaiters followed tardily in the suit of the civilian clothing of the time and were replaced by trousers in the first quarter of the 19th century. The helmet was also introduced at about this period, and is at present retained by the dragoons of most armies and by the German infantry.

The period after Waterloo was distinguished even above the 18th century for the extreme uncomfortableness of the uniforms and their total unfitness for any activity whatever. This was swept away in England by the reaction due to the Crimean War. At about the same time or a little earlier the coatee gave way to the looser tunic. The dress uniforms of to-day date back in essentials to this epoch. The dull service uniforms worn by all armies in the field at the present time are designed for comfort, usefulness and inconspicuousness and date back to the border warfare in India during the latter half of the 19th century. Their general use is due to the experiences of the British in the Boer War. America soon followed the British khaki with its olive drab. Germany adopted a greenish gray, Italy a bluish gray and Russia a

grayish green. The Belgian khaki and the French horizon blue were only introduced after the unsuitability of the old brilliant uniforms had been manifested in the first months of the European War. The steel helmets in general use at present were introduced a little later.

The enlisted man in the United States army has a khaki or olive-drab service uniform, a blue dress uniform, a fatigue uniform of blue denim and in some cases a white uniform. The facings of the dress uniform and the hat-cord of the service hat are of the corps color, which are blue for the infantry, yellow for the cavalry, red for the artillery, red and white for the engineers, orange and white for the signal corps, maroon and white for the medical corps, straw-color for the quartermaster corps, red and black for the ordnance corps and green for the service school detachments. The officers' uniforms, besides service, dress and white uniforms much like those of the enlisted men, are the full dress, the special evening dress and the mess jackets, worn on special occasions. The history of the uniforms of the United States army lends itself into a division into periods separated by the various wars in which the United States has taken a part. During the American Revolution the uniforms were governed by no particular principle, if the troops were so lucky as to be uniformed at all. After the end of the Revolution, the French uniforms were taken as a pattern and blue was made the color of the infantry and artillery uniforms, which were faced with white. Soon afterward, when cavalry regiments were raised, they were similarly uniformed, first in green with white facings and then in green with black facings. These uniforms survived in a more or less modified form until the War of 1812 when the sudden influx of large numbers of variously equipped militia made the re-establishment of a definite uniform desirable. The French model was again adopted, with dark-blue coatees and white or light-blue breeches or trousers. From the Mexican War to the beginning of the Civil War the uniform consisted of a long coat and trousers, with a shako or slouch hat. The corps colors were adopted at this period, in a form not widely divergent from that of the present day. The Civil War universalized the service or undress uniform of blue, light in the coat and dark in the trousers. This again mimicked the uniform of the French, but after 1870 the success of the Germans caused the cut of the uniforms and the spiked helmets to be modeled after those of the Germans. For service the slouch hat and leggings were worn. The uniform was found to be unsuited for active service in the Spanish War and was replaced by one of khaki. After the war this color was retained for the service uniform, which was patterned after that of the British. The dress uniform retains the original blue color.

The British dress uniforms are perhaps the most varied and gorgeous of those of any country in the world. Their general color is red, though certain rifle regiments, etc., form exceptions. They are faced with the color of the regiment. The khaki field-service uniforms much resemble those of the United States, except for the pleated pockets and the collar, which is box-cut for the officers and turns over in the uniforms of the enlisted men. Rolled leggings known as puttees are used. While this uniform is practically the same throughout the army, the Highland Scotch regiments retain their tartan kilts, though they cover these with a khaki apron. The present field-service uniform dates back to the Boer War of 1899–1902.

Blue coats and red trousers make up the dress uniform of most French soldiers and before the European War were worn on active service. The long coat of the infantryman with its bottom corners buttoned back is characteristically French. The European War has caused the French uniform — particularly that of the officers — to be assimilated to that of the British. The color, however, is light blue.

The Italian infantryman wears a dark blue tunic, gray trousers and a cloth shako. In the cavalry the trousers are replaced by breeches and the shako by a busby in lancer regiments and a helmet in dragoons. The Bersaglieri wear a broad-brimmed felt hat with a plume of cock's feathers. The service uniform is brownish gray.

Before the collapse of Russia in 1917 the uniform was in general green in color and in the infantry consisted of a large peaked cap, a loose blouse, trousers and high boots. The facings varied with the regiments. The cavalry wore blue or green coats with gray breeches. Cossack and Siberian regiments wore high sheep-skin caps. The field service uniform was of a khaki color.

The general color of the German dress infantry tunics is Prussian blue, except in Bavaria, where it is light blue. The trousers are black and the facings vary with the different regiments. The head-dress on some occasions is a brimmed or brimless cap, on others a spiked helmet. The tunics of rifle regiments are green and they wear shakos. Cuirassiers wear metal helmets and white tunics. The tunics of uhlans and dragoons are blue and their helmets are made of leather. The several regiments of hussars wear helmets of different colors and their head-dress is a busby of brown fur. Engineer and artillery uniforms are entirely blue. The field uniform is a brownish gray. The ordinary head-dress is retained but covered by a gray cover. The Austrian tunic is generally dark blue, except that rifle regiments and engineers wear gray, while the artillery wears brown. The infantry wears light blue trousers, except in rifle regiments, where gray trousers are worn. Gray trousers are also worn by engineers. Mounted troops wear red breeches. The infantry head-dress is a shako. Hungarian uniforms are patterned after the Austrian with the exception that elaborate braiding is used on the trousers. The field-service color of Austria-Hungary is bluish gray and a special gray cap is worn, except in cavalry regiments, which use their ordinary head-dress, protected by a gray cover.

Other countries incline as a rule either to the German or the French model of uniform. The French influence preponderates in Switzerland, Holland, Belgium, Spain, Portugal, Rumania, Greece, Brazil and Argentina. The uniforms of the Scandinavian countries, Turkey and Chile are German in cut, Serbia combines French and Austrian influence, while the uniforms of Bulgaria are distinctly Russian. The British influence is preponderant in many field-service uniforms, such as those of China, Japan,

Greece and the United States. China and Mexico have borrowed to some extent from the United States, while the Cuban uniforms resemble the American ones very closely.

Naval uniforms are much the same throughout the world. The British naval uniform, after which all others have been patterned, consists for the men of a jumper or overshirt of the familiar navy pattern, bell-shaped trousers and a "pancake" cap, with a ribbon indicating the ship to which its bearer belongs. The blue undress or service uniform of the British officer consists of a peaked cap, a double-breasted coat with brass buttons and blue serge trousers. There are various mess and dress uniforms. The American uniforms closely resemble the British, except that in the officers' blue service dress a braid-trimmed blouse is worn instead of a coat. The Russian sailors wear a military tunic when on shore duty. In the German navy the cap-ribbons are very long and a jacket with many buttons is worn over the overshirt. (For the insignia of rank in the various armies and navies of the world, see MILITARY INSIGNIA OF RANK). Consult the publications of the War and Navy Departments of the various governments and Detaille, 'L'Armée française' (Paris 1889); id., 'Catalogue illustré de l'exposition rétrospective militaire du ministière de la guerre' (ib. 1890); Farmer, J. S., 'Regimental Records' (London); Knotel, R., 'Handbuch der Uniformenkunde' (Leipzig 1896); Lienhardt and Humbert, 'Les uniformes de l'armée française'; Ogden, H. A., 'Uniforms of the Army of the United States, 1779–1888' (Washington 1908).

UNIGENITUS, ū-nĭ-jĕn'ĭ-tŭs, the bull (1713) of Clement XI by which 101 theological propositions of a Jansenistic tenor contained in the writings of Pasquier Quesnel are condemned as heretical, scandalous, impious, etc. (See QUESNEL; JANSENISM). The title of the bull is derived from its opening words *Unigenitus Dei Filius*. Among the doctrines alleged to be contained in Quesnel's writings ('Moral Reflexions' on the Gospels and the whole New Testament) is this, that all love except the supernatural love of God is evil; that without this supernatural love there can be no true hope, observance of the law or religion; that every prayer made by a sinner is itself sinful; and that the Church is made up of the elect alone. While Louis XIV lived he compelled obedience to the bull; but after his death, 1717, and the succession of his great-grandson, Louis XV, under a regency, those ecclesiastics who were opposed to the Roman decisions, among them Noailles, archbishop of Paris, and four other bishops, made appeal to a future council of the Church against the Pope. Another appeal was made "from the pope ill informed to the pope better informed"; but the popes who succeeded Clement XI down to 1730, namely, Innocent XIII, Benedict XIII and Clement XII, would not entertain the appeal; the assembly of the French clergy in 1723 petitioned the king to uphold the Unigenitus with all the power of the state; in 1727 one of the appellants, Soanen, bishop of Séez, was condemned by a provincial church council and was banished by the government; even Noailles in 1728 went over to the side of the Ultramontanes, and in 1730 the Sorbonne formally accepted the bull; the same year the parliament of Paris was compelled to register it.

UNIMAK, oo-nĭ-mäk', an island of Alaska, the largest of the Aleutian Islands, about 75 miles long and 25 miles wide. A lagoon called Isanotski, of False Pass, separates the island from the mainland of the Peninsula of Alaska. Like the adjacent islands, it is volcanic. Shishaldin, an active volcano, is about 9,000 feet high. Sulphur abounds on the slopes and base, in crevices, of Shishaldin and near Progrumnoi volcano (5,523 feet high), in the western part of the island. The island is rocky and almost destitute of trees. The villages are few and small. The population is made up of Aleuts.

UNION, ū'nyŏn, Me., town in Knox County, on the Georges Valley Railroad, a short line which extends from Warren to Union. The town contains the villages of Union, South Union, North Union and East Union. It was settled in 1744 and was first called Taylor Town. In 1786 it was organized as the Plantation of Sterlington, but the same year it was incorporated and took the name Union. In 1811 a part of the town was set off and called the town of Washington. The chief manufacturing establishments are mowing-machine works, machine shops, carriage and furniture factories and organ works. Stoves are made here and considerable attention given to farm and dairy products. Pop. 1,233.

UNION, La, lä oo-nē-ōn', Philippines, a province of the island of Luzon, in the southwestern part of northern Luzon, bordering on the China Sea; bounded on the north by Ilocos Sur, on the east by Lepanto and Benguet and on the south by Pangasinán; length, north and south, 51 miles; greatest width, 31 miles in the north, narrowing to 10 miles in the south; area, 867 square miles. The province is mountainous in the east, the western mountain sides sloping abruptly to the coast plains. There are numerous small rivers. The soil is well cultivated; tobacco, rice, corn, cotton, sugar and chocolate are the principal products; large quantities of sibucao, a valuable dye plant, grow on the mountains. Livestock raising is one of the principal industries of the province; carabaos and cattle, horses and hogs are raised. The west coast road of Luzon traverses this province; this is paralleled by a telegraph line and also the Manila and Dagupan Railroad; there are no roads, however, which extend any distance into the interior. Civil government was established in August 1901; and at the close of that year the provincial governor reported the province in a peaceful and prosperous condition. Pop. 138,000, mostly Igorots and Ilocanos.

UNION, La, Salvador, a seaport and capital of the department of the same name, at the base of the Conchagua volcano, rising from the west shore of Union Bay, a landlocked inlet of the Gulf of Fonseca. An active domestic and coasting trade is carried on. Pop. 5,300.

UNION CHRISTIAN COLLEGE, located at Merom, Ind. It was chartered in 1859 under the auspices of the Christian Church and opened to students in 1860; the government of the college is vested in a board of 15 trustees elected by the stockholders from nominations made by the Church conferences of Illinois, Indiana and Ohio. The college has, in addition

to the regular collegiate departments of instruction, a Biblical Department, a Normal Department, a Department ot Music, a Preparatory Department and special courses in elocution and physical culture. There are two collegiate courses, the classical and scientific leading to the degrees of A.B. and B.S. respectively; a limited number of electives are offered in each course; and a thesis is required for the obtaining of a degree. The degrees of A.M. and M.S. are conferred for graduate work. The Biblical Department and the Normal Department both offer three years' courses. The college is open to men and women on equal terms. The students maintain two literary societies. In 1901 an offer of $30,000 for the endowment was received from F. A. Palmer of New York, on condition that the college raise $20,000. The condition was met by 1902, and thus $50,000 added to the endowment fund. The students number about 200 and the faculty 11.

UNION CITY, Ind., city, Randolph County, on the Pittsburgh and the Cleveland, Cincinnati, Chicago and Saint Louis railroads, about 80 miles northeast of Indianapolis, and 32 miles east of Muncie. It is near the Ohio boundary Union City is in an agricultural and stock-raising region; and the forests contain valuable hard woods, as ash, oak, hickory, walnut and chestnut. The chief manufacturing establishments are flour mills, creameries, furniture factories, automobile factories, wheel and carriage works and machine shops. There are a high school, public and parish schools, hospital and a public library. Pop. 3,209.

UNION CITY, Mich., village in Branch County, on the Saint Joseph River, and on the Michigan Central Railroad, about 55 miles southwest of Lansing and 28 miles southeast of Kalamazoo. It is in a fertile agricultural region. The chief manufacturing establishments are a flour mill, creameries, a machine shop and lumber mills. It ships a considerable amount of farm and dairy products and fruit. Pop. 1,340.

UNION CITY, Pa., borough in Erie County, on the Pennsylvania and the Erie railroads, about 25 miles southeast of Erie. It is in an agricultural and oil region. The chief industrial establishments are flour mills, barrel factories, planing and grist mills, a powdered-milk plant, wagon and carriage works, furniture factories, oil-refinery, a tannery and a pump factory. Cabinet ware and dairy products are among the shipments to outside markets. The educational institutions are a high school, public and parish elementary schools, a business college, and a public library. Pop. 3,684.

UNION CITY, Tenn., town, county-seat of Obion County, on the Nashville, Chattanooga and Saint Louis and the Mobile and Ohio railroads, about six miles from the Kentucky border and 110 miles northeast of Memphis. It is an agricultural and stock-raising region and nearby are extensive timber lands. The chief manufacturing establishments are lumber mills, ice factories, canneries, furniture works, cotton mills, spoke factories and machine shops. The principal products shipped to other markets are farm and dairy products, fruit, cotton and lumber products. The educational institutions are Union City High School and Training School, public elementary schools for white and for colored pupils and a school library. Nailling Hospital is located in Union City. Pop. 4,389.

UNION COLLEGE, located at College View, a suburb of Lincoln, Neb. It is a part of the school system of the Seventh-day Adventists; the site was chosen in 1890, and the college opened to students in 1891. It is avowedly denominational and observes the Sabbath on the seventh day (Saturday). It is open to both men and women. It offers two regular college courses leading to degrees, the literary and scientific, and confers the degrees of A.B. and B.S. A limited amount of elective work in advanced courses is allowed in the senior year. There is also an academic course of four years, and a number of special courses, including the ministerial course (three years), the advanced normal course (three years), the elementary normal course, preparatory medical course, preparatory nurses' course, commercial course, phonography course and a German Biblical and a Scandinavian course, the two last mentioned being especially designed to train missionary workers among Germans and Scandinavians. Instruction is also given in music and art. In 1902 it was decided that manual training should be required of every student. Instruction and practice work are given in printing, broommaking, carpentering, blacksmithing, metal working, electrical work, tailoring, sewing and cooking. *The Central Advance* (a denominational paper), a German and a Scandinavian paper are printed at the college shop. The campus consists of 22 acres on elevated ground; the chief buildings are the main building and the dormitories or "homes." The library contains over 6,000 volumes; the students in all courses number about 550, with a faculty averaging 25 members.

UNION COLLEGE, located at Schenectady, N. Y. See UNION UNIVERSITY.

UNION FLAG, or **UNION JACK,** the national flag of Great Britain and Ireland, is a composite of the prominent features of the flags of England, Scotland and Ireland. The first union flag was made upon the accession of James I, and from the fact that that sovereign signed himself "Jacques" the flag has been improperly nicknamed the Union Jack (a "jack" properly being a flag flown upon the jack-staff of a ship). The first national flag in 1606 combined the English banner of Saint George (argent, a cross gules) with the Scottish banner of Saint Andrew (azure, a saltire argent). In 1707 the flag was revised, becoming in heraldic terms azure, a saltire argent surmounted by a cross gules fimbriated of the second. When Ireland was united with the kingdom of Great Britain the flag was again altered, the red cross of Saint Patrick being introduced and forming the present Union Jack. In heraldic terms it is: azure, the crosses saltires of Saint Andrew and Saint Patrick quarterly per saltire counterchanged argent and gules, the latter fimbriated of the second, surmounted by the cross of Saint George of the third fimbriated as a saltire. This was first hoisted on the Tower of London 1 Jan. 1801. The flag is the national flag for use on shore and for land forces; it is used at sea only on a

ship bearing the English sovereign, when it is hoisted at the main mast, and at the main mast of the flag-ship of a fleet commanded by an admiral. With a harp on a blue shield displayed in the centre it is the flag of the lord-lieutenant of Ireland. With the star and device of the order of the Star of India it is flown by the governor-general of India. When this flag design occupies the upper corner next to the staff of a red, white or blue field the flag so formed is called the red, white or blue ensign and is the flag for use on shipboard. Merchantmen carry the red ensign, and all British war vessels carry the white ensign divided into four quarters by the cross of Saint George. See FLAGS OF FOREIGN NATIONS.

In the United States the term «Union Jack» is applied to the blue flag with white five-pointed stars (one for each State in the Union), used in the navy. The flag is usually displayed when the vessel is in port.

UNION LABEL, a trade-mark adopted by a trades union to be placed on articles manufactured wholly in union shops, under union rules by their sanction. The union label originated in 1896 with the cigarmakers of San Francisco in their conflict with Chinese labor. Since then its application has spread till all trades-unionism looks to it as one of the most successful means of waging the struggle with combined capital. By agreement with individual manufacturers the labels, copyrighted by the unions, are attached to the various products of factory and mill, each box of cigars, for instance, each newspaper, each garment, and so on. While many unions have their copyrighted labels, a large number employ the common label of the American Federation. Many States have passed laws imposing penalties upon counterfeiters of labels, and upon users of counterfeit labels. See AMERICAN LABOR; LABOR; UNIONISM, etc.

UNION LEAGUE OF AMERICA, The, began in 1862 in order to check the spread of disaffection to the United States government and to «make loyalty effective.» The movement was spontaneous; the members of the United States Sanitary Commission began the organization in 1862, in Ohio, Philadelphia and New York. Leagues were formed all over the North before the end of 1863. The members were pledged to repudiate any political belief that conflicted with unconditional loyalty to the Union. Several similar orders were absorbed by the Union League. The organization distributed more than 5,000,000 political pamphlets; recruited negro regiments; sent teachers to instruct the negroes and demanded negro suffrage in 1865. The league was gradually extended into the South among the «Unionists,» and during 1865–66 had a strong membership of whites in the mountain districts of that section. In 1867 negroes were admitted to the order in the South and at once nearly all of the whites deserted. From 1867 to 1876 the league and its offshoots formed the «machine» of the Radical party in the South. It controlled the negro vote absolutely and organized it well; it made all nominations for office, and severely disciplined those who disobeyed orders. A constitution and ritual were adopted for use in the South. There was a weird initiation ceremony to impress the negroes. The members swore to vote for no one except members of their own order. An ex-Confederate could not join unless he would acknowledge that his course during the war had been treason, and under no circumstances was he eligible to office in the order or to become a candidate for political office. The administration of the league was in the hands of the so-called carpet-baggers or political adventurers from the North. The local assemblies were called councils; these together formed the Union League of America, with headquarters in each Southern State and general headquarters in New York. In the councils the negroes were drilled in the faith of the Republican party, a catechism being prepared for that purpose. There was complaint that the league was a cause of disorder and violence among the blacks on account of its incendiary teachings. At one time it was said that the membership reached 500,000 in the South. In the North after 1865 the order gradually died out, the surviving leagues becoming social clubs, the chief of which is the Union League Club of New York City, incorporated 16 Feb. 1865. It has had a great influence on Republican politics and of late years has opposed the progressive members of that party. By many it is considered one of the greatest strongholds of conservatism and reaction in America. As an institution of Reconstruction the Union League was most important. The rigid organization and the strict control imposed by it upon the blacks made it possible for them to vote as a race and vote the Republican ticket. Without the admirable discipline of the order, the few leaders of the Radical party in the South would have been unable to prevent the Conservative or Democratic party from controlling the votes of the negroes, thus preventing the objects of the Reconstruction.

UNION LEAGUE CLUB, The, a social and political club organized, in 1863, in New York, by members of the local Republican party. It was incorporated in 1865, its avowed object being «to promote, encourage, and sustain by all proper means, absolute and unqualified loyalty to the government of the United States; to discountenance and rebuke, by moral and social influences, all disloyalty to said government and every attempt against integrity of the nation»; and also to establish a library and art gallery for the collection of literature and works of art, and military trophies relating to the war. The club has a membership of about 1,800, and its headquarters are at its palatial clubhouse, 39th street and Fifth avenue, New York City.

UNION PACIFIC SYSTEM. The Union Pacific Railroad was organized 1 July 1897, under an act of the legislature of Utah approved 22 Jan. 1897, «to carry out the reorganization of the Union Pacific Railway Company,» and now includes the Union Pacific Railroad, the Oregon Short Line and the Oregon Railroad and Navigation Company. The northerly or main line runs westward from Council Bluffs (Omaha) across the central part of the State of Nebraska, a co-ordinate line running almost parallel, about 150 miles to the south from Kansas City across the State of Kansas, and to Denver, Colo., whence it trends northward, joining the main line at Cheyenne, Wyo. Thence the

road continues westerly across the southern section of Wyoming and to Ogden, Utah. From this point the system makes use of its subsidiary, the Oregon Short Line, traversing southern and western Idaho, to Huntington, Ore.; and thence by the subsidiary Oregon-Washington Railroad and Navigation Company's road to Portland, Ore., and Seattle, Wash.

The total mileage operated, as of 31 Dec. 1917, was 7,714.97 miles, of which 3,597.80 is of the Union Pacific Railroad, 2,148.65 of the Oregon Short Line, and 1,968.52 of the Oregon-Washington Railroad and Navigation Company. The system is prolific of branches, the main lines covering 3,534.64 miles, and the branches, 4,180.33 miles. Besides these roads there is operated 302.22 miles of leased lines, and the company enjoys trackage rights over 254.30 miles of other railroads.

The total operating revenue for the calendar year 1917 amounted to $130,101,864; earned by the transportation of 9,315,764 passengers and 23,874,511 tons of freight. The passenger travel averaged 115.08 miles per trip, at a cost of the traveler of 2.326 cents per mile — aggregating in the year 1,072,053,665 miles and $25,207,229. The freight haul average 448.3 miles per ton, at an average charge of 0.851 cent per mile — aggregating in the year 10,702,976,670 ton-miles and $93,347,832.

The operating expenses for the year were $77,295,158, making the net operating revenue $52,806,706. Taxes amounted to $8,451,691, leaving the net operating income at $44,355,015. Non-operating income amounted to $13,170,361 and deductions for rentals, interest, etc., totaled $15,998,875, leaving the net income at $41,536,500.

Dividends to preferred stock amounted to $3,981,740, and to common stock (16.89 per cent), $22,229,160. The sum of $15,313,973 was appropriated for the road and equipment.

The equipment of the road on 31 Dec. 1917 consisted of 1,538 locomotives, with an aggregate tractive capacity of 52,714,182 pounds. Passenger coaches, mail and baggage cars numbered 1,150, of which 574 were of steel. Freight cars of all types numbered 41,247.

The entire investment in the road and its equipment on 31 Dec. 1917 stood at $632,813,457. Investments in other companies totaled $268,733,986.

The total stock outstanding on the date cited amounted to $321,836,600 and the long term debt was $335,099,365. The credit balance of the profit-and-loss account was $124,354,104. The grand total of the system's resources was $921,273,292.

In addition to operating the railroad, the company operates four steamer lines: (1) Portland to Astoria, Ore., 98 miles; (2) Astoria to Megler, Wash., 5 miles; (3) Riparia, Ore., to Lewiston, Idaho, 78 miles; and (4) Amwaco to Harrison, Idaho, 6 miles.

History of the Road.— The Union Pacific Railroad Company was formed "for the purpose of acquiring, constructing, and owning railroads in the State of Utah, and elsewhere, with specific authority to acquire the railroads, properties, franchises and land grants formerly belonging to the Union Pacific Railway Company." That corporation owned four divisions of railroad, with a total length of lines of 8,172 miles. In 1893, receivers were appointed for all lines except those owned jointly with other companies. Afterward, separate receivers were appointed for some of the controlled roads.

When the Union Pacific Railway Company was first placed in the hands of receivers, the bonds outstanding aggregated $78,470,000. In addition to this amount, the government subsidy bonds amounted to $33,540,000. On this latter amount, the unpaid interest was $18,194,000. At that time the share capital of the company aggregated $60,869,000. A short time after the receivers had taken possession of the property, legislation to guarantee a Federal government lien at 3 per cent was proposed in Congress. The security holders at the same time put forward a reorganization method. Both plans were defeated.

In 1897 the main line, from Council Bluffs to a point five miles west of Ogden, Utah, a distance of 1,048 miles, together with 70 per cent of the equipment, was sold under foreclosure and purchased by the reorganization committee, which, later, borrowed $44,000,000 from a syndicate. Following this event many extensions were made. In 1899 control was acquired of the Oregon Short Line Railroad. This purchase was followed by that of the Oregon Railroad and Navigation Company property. In 1901 by purchase of a controlling interest, possession was gained of the Southern Pacific Railroad Company and, three months later, control of the Northern Pacific Railroad Company was acquired. These interests it was afterward compelled to relinquish as in contravention of the anti-trust law. The Union Pacific has important connections with Southern California points by virtue of its affiliation with the Los Angeles and Salt Lake Railroad.

UNION OF SOUTH AFRICA, a legislative union of the four self-governing colonies of South Africa, effected by the South Africa act, which was promulgated by royal proclamation of Great Britain 20 Sept. 1909, and became effective 31 May 1910. The original provinces of the union were Cape of Good Hope, Natal, Transvaal and Orange Free State. United they are bounded on the north by the former colony of German Southwest Africa, Bechuanaland Protectorate, Matabeleland and Portuguese East Africa, on the east by the Indian Ocean, on the south by the Atlantic Ocean and on the west by the Atlantic Ocean and the former colony of German Southwest Africa.

The area of the Union is 473,075 square miles, distributed as follows: Cape Colony, 276,966 square miles; Natal, 35,290 square miles; Transvaal, 110,430 square miles; and Orange Free State, 50,389 square miles. The total population of the Union is 5,973,394 (1,276,242 Europeans), distributed as follows: Cape Colony, 2,564,965; Natal, 1,194,643; Transvaal, 1,686,212; Orange Free State, 528,714. The capitals of the four provinces composing the Union are Cape Town (Cape Colony), Pietermaritzburg (Natal), Pretoria (Transvaal), and Bloemfontein (Orange Free State). The principal cities, with populations, are: Johannesburg (119,953), Durban (31,783), Cape Town (29,863), Pretoria (29,611), Pietermaritzburg (14,737), and Bloemfontein (14,730). The total imports for 1916 were valued at $188,622,000, and exports $104,237,000, the United States being credited with 15.7 of the former and 14.8 of the latter. The public debt of the Union ex-

ceeds $756,000,000. There are 8,924 miles of railway and over 16,000 miles of telegraph line.

Provision was made by which other British colonies might join the Union. Before the day appointed for the establishment of the Union (31 May 1910), the elective members of the senate of the Union to represent the respective provinces were chosen by the two legislative houses of each colony sitting together, and within six months after the date of the establishment the first parliament was summoned. Under the enactment of the British Parliament it was provided that the new commonwealth was to be governed by a governor-general appointed by the king, an executive council appointed by the governor-general, and a Parliament of two houses, the membership of which was to be limited to persons of European descent. Ministers of state, not more than 10, administer departments. All the powers, authorities and functions which at the establishment of the Union were in any of the colonies vested in the governor or in any authority of the colony, so far as they continue in existence and are capable of being exercised, are vested in the governor-general or the governor-general in council, or in the authority exercising similar powers under the Union, except such powers and functions as are or may be expressly vested in some other authority. The command of the naval and military forces is vested in the governor-general. The seat of government is Pretoria but the legislature sits at Cape Town. A principal feature of the membership in the senate and house of assembly is the tenure of office. The first senate was made up of eight senators nominated by the governor-general in council for 10 years, and for each of the original provinces eight senators are to be elected for 10 years by the two houses of the colonial legislature sitting together. The house of assembly consists of members chosen in electoral divisions in numbers as follows: The Cape of Good Hope, 51; Natal, 17; Transvaal, 45; Orange Free State, 17. With the increase in European population the representation will increase. The house of assembly was to continue five years from the date of its first meeting unless sooner dissolved. All money bills originate in the house of assembly, but the assembly may not pass a bill for taxation or appropriation unless it has been recommended by message from the governor-general during the session.

Each separate colony has at its head an administrator, appointed by the governor-general, an executive committee of four and a provisional council of 25 members or a number equal to the number of members which the colony sends to the Parliament of the Union. The provincial committees and councils have authority to deal with local matters, such as finance, elementary education, agriculture, charity, municipal institutions, local works, roads and bridges, markets, fish and game, etc. The governor-general approves these local ordinances.

The administration of justice is by the Supreme Court of South Africa and other courts within the Union and in the provinces. The common law of the Union is the Roman-Dutch law. Prior to 1913–14 the expenses of the four provinces were entirely defrayed from grants by the Union government. Under the Financial Relations Act of 1913 certain revenues were transferred or assigned to the provinces and the grants by the Union government were limited to 50 per cent of the total normal or recurrent expenditure of the provinces. The capital expenditures of the several provinces are financed by redeemable loans from the Union government. English and Dutch are the official languages and are treated as on an equal footing. The administration of native affairs and those pertaining to Asiatics is vested in the governor-general in council.

The industrial development of South Africa will continue to be, undoubtedly, along agricultural lines. The principal product is maize and the secondary products are bacon, beef, lard and hides. Conditions induced by the World War gave a great stimulus to wheat-growing and dairying. Sheep-farming is well established and capable of being greatly extended. Another prosperous industry is ostrich farming. Cotton, mohair and sugar and tea have become important products. The cultivation of tobacco and fruit is highly productive and wine-growing is in a flourishing condition. The aim will continue to be the upbuilding of an export trade and the extension of railway facilities from the agricultural regions. The wheat crop reached 5,500,000 bushels in the years of the war, while the maize crop of 1917 was 36,000,000 bushels. Butter to the amount of 19,412,000 pounds and cheese to the amount of 4,266,000 pounds were produced in 1917. The latest live-stock census showed 5,796,949 cattle, 719,414 horses, 93,931 mules, 336,710 donkeys, 746,736 ostriches, 30,656,659 sheep, 11,762,979 goats, 1,081,600 pigs and 10,533,909 poultry. Wool exports in 1917 amounted to 117,657,142 pounds and of mohair to 3,690,828 pounds. In the same year hides and skins to the value of $13,000,000 were exported. Cotton-growing is on the increase as the plant is a good drought-resistant. The crop is now about 3,000,000 annually. Tobacco is produced to the extent of about 9,000,000 pounds annually. Cane-sugar to the extent of 115,000 tons was produced in 1917. The tea crop in the same year was 1,747,000 pounds. The main source of South African prosperity is, however, gold, coal and diamond mining. The output of diamonds in 1917 was valued at £7,713,810 and of 1916 £5,728,391, of which Cape Colony produced £4,057,928, the Transvaal, £933,643 and Orange Free State, £736,820. The gold production of the Union was valued at £38,923,921 and was almost entirely credited to the Transvaal. Coal production in 1916 totaled 2,739,665 short tons, the Transvaal and Natal leading. Cape Colony led in salt production, having more than half of the 106,303 tons mined. The latest statistics show that 340,000 persons (of all races) are engaged in mining, of which 47,000 are Europeans. Machinery, clothing, chemicals and dynamite are some of the principal imports. In 1917 3,889 vessels (overseas and coastwise) entered the ports of the Union; total tonnage 9,253,000 tons. The Colony is defended by a permanent force, coast garrison, citizen, naval volunteer and special reserves.

After the outbreak of the World War a rebellion, of which the chief leader was Christian De Wet, broke out, but it was promptly suppressed by General Botha. In addition to send-

ing contingents for service with the British forces to France and Belgium and later in East Africa and Nyassaland, 65,000 troops were raised and sent against German South-West Africa, a campaign that was brought to a successful termination in July 1915. See WAR, EUROPEAN.

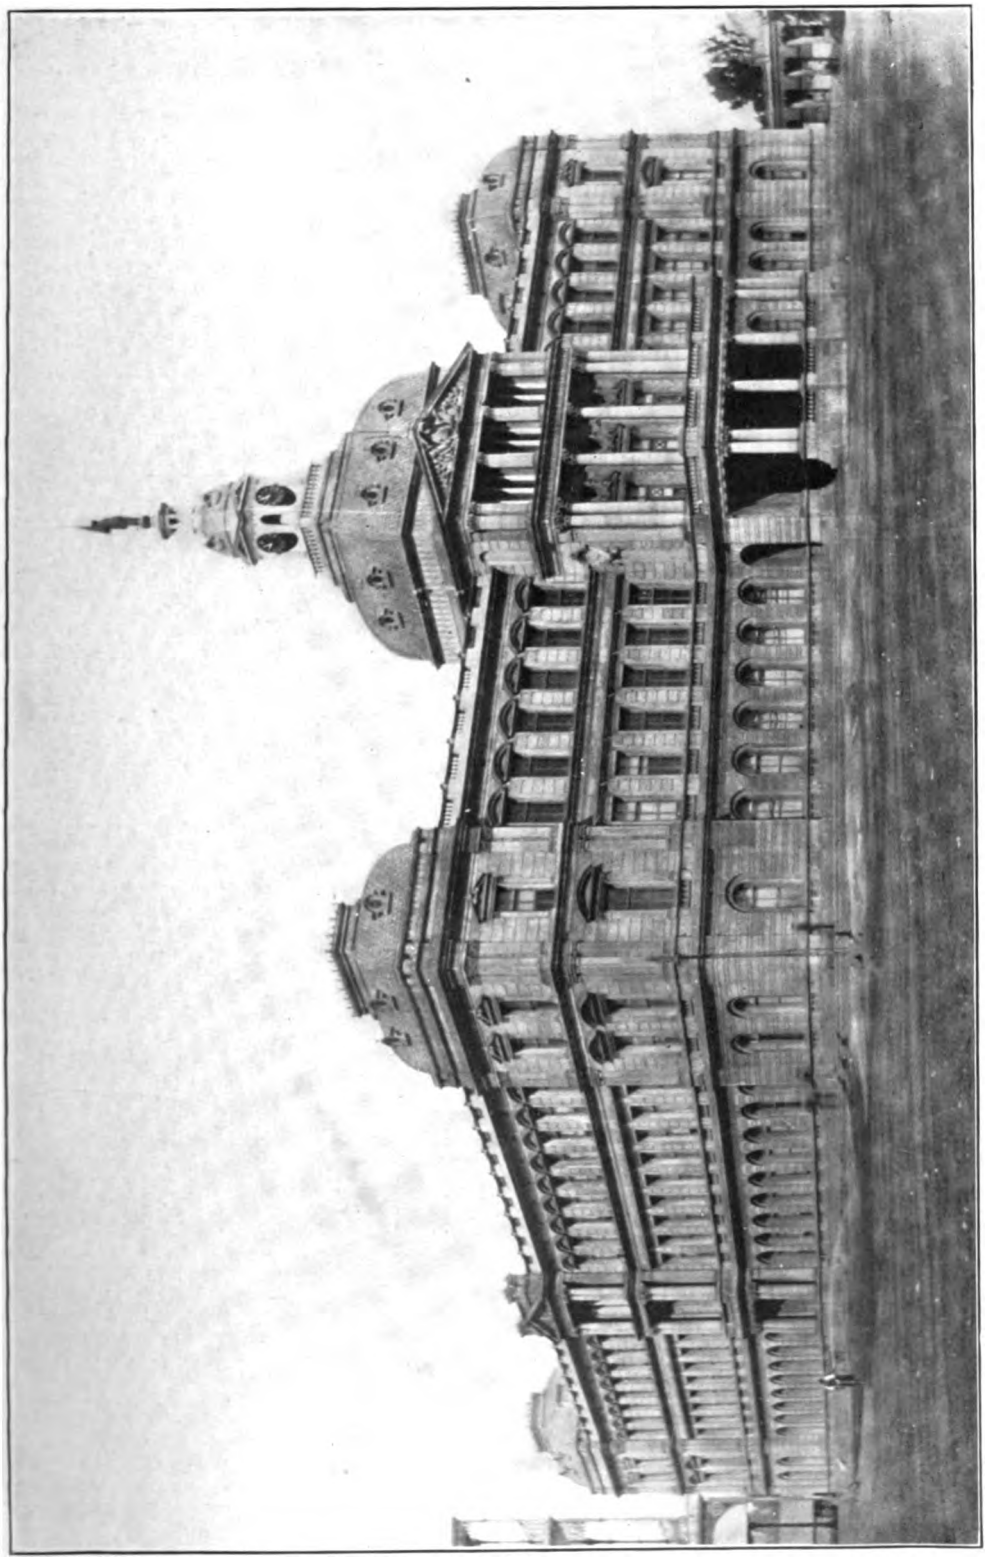
UNION SPRINGS, Ala., city, county-seat of Bullock County, on the Central of Georgia Railroad and the Birmingham and South Railroad, about 40 miles southeast of Montgomery and 175 miles northeast of Mobile. It is in an agricultural and fruit region. The chief manufacturing establishments are cotton gins, cottonseed-oil mills, cotton-mills, spoke and handle factories, grist-mills and a machine shop. The educational institutions are a high school, founded in 1899, public graded schools and several private schools. Union Springs was incorporated in 1844. Pop. 4,055.

UNION THEOLOGICAL SEMINARY IN THE CITY OF NEW YORK, The. It was founded in 1836, under the auspices of the Presbyterian Church; the directors and professors of the seminary give their assent to the Westminster standards of this Church, but students of all denominations are freely admitted. The seminary offers the following courses: (1) A three-years' course leading to a diploma requiring the study of Greek and Hebrew; (2) a three-years' course leading to the degree of B.D., requiring more hours' work and a higher standing than the diploma course, special work in some department chosen by the student and including a thesis; (3) a four-years' course requiring one year's graduate work and a thesis; (4) special and partial courses. For admission to the degree courses college graduation is required; for the diploma course college graduation or examination in Latin, Greek, philosophy, English and history. Part of the work in the regular courses is elective and some electives are provided for at Columbia and New York universities. The curriculum of the seminary includes courses in Old and New Testament philology and exegesis, biblical, systematic and practical theology (including study of missions), apologetics, Christian ethics, church history and history of religion, voice culture and sacred music. Training in actual Christian work is provided in churches and chapels, public institutions and settlement work; the Union Settlement is closely related, though not officially affiliated with the university. Seminary extension courses for lay workers were established in 1901. There are a number of undergraduate scholarships, graduate scholarships and two fellowships. The seminary buildings contain a chapel, lecture-rooms, library, museum, reading-room, gymnasium, social-room, and dormitory-rooms. The library in 1919 contained 130,131 volumes, including special collections in American and English history. The students in 1917 numbered 226, including the two Fellows and the graduates.

UNION UNIVERSITY, formerly Southwestern Baptist University, is located at Jackson, Tenn. The Baptists of Tennessee, realizing the necessity of an institution under their control, set about in 1845 for the establishment of such a school, especially for an educated ministry. It was located at Murfreesboro, under the name of Union University; during the Civil War the building was damaged, the equipment destroyed and endowment rendered worthless; these difficulties were partly overcome, and the University continued its work until 1873, when it was further crippled by an epidemic of cholera in Murfreesboro, and all exercises suspended. In 1875 a new charter was obtained and the name Southwestern Baptist University was adopted; since that time its prosperity has been continuous and the endowment has largely increased. In September 1907 by action of the board of trustees, the university resumed the original name, Union University. The organization of the university consists of (1) the College Department; (2) the Department of Theology; (3) the Teachers' College; (4) the Business School; (5) the Department of Oratory and Physical Development; (6) the Department of Music, and (7) the University Academy. The College Department offers two courses, leading to the degrees of A.B., and B. S.; certain studies are required in each course, while others are elective. The degree of A.M., is conferred for post-graduate work. The courses of the Theological Department do not lead to a theological degree, but are elective and receive some credit toward the degree of A.B., or B.S. The university is coeducational and the dormitory for young women was erected in 1897. In January 1912 the two main college buildings were destroyed by fire, but new buildings, in some respects very superior to the old ones, were erected. The library contains approximately 10,000 volumes. The students number 300; the Teachers' College over 200 and the faculty, 20.

UNIONIDÆ, a family of bivalved mollusks, the fresh-water mussels (q.v.).

UNIONISM, the principle of operating industries by union labor; that industrial system through which corporations or other employers hire their men by collective bargaining with organized bodies of workmen. (See AMERICAN FEDERATION OF LABOR; TRADE UNIONS; STRIKES AND LOCKOUTS). Although less than 2 per cent of the active workers in America belong to trades unions, yet this organized fraction dominates the policies in all the large industries, and has been very active for a generation in raising wages, shortening hours and improving shop conditions. It is a notable fact that the six leading countries in the Great World War are each imbued with unionism. In 1913, the year before the war broke out, the number of trade unionists in the leading nations was as follows: United Kingdom, 4,000,000; German Empire,



The House of Parliament, Pretoria

3,800,000; United States, 3,000,000; France, 1,050,000; Italy, 975,000; Austria-Hungary, 750,000. No other country had as many as 225,000 union workers. The unions of Great Britain, Germany and the United States expended each close upon $20,000,000 in that year to maintain their organizations, provide benefits, etc.

In the United States.— While the unions of Great Britain increased from 1,500,000 to about 2,800,000, those of the United States grew from 548,300 in 1900 to over 2,000,000 in 1910. The causes for this growth were, in the main, the great prosperity of all workers, the trust or combination idea, the many strikes and finally labor's natural growth. In 1895 the American Federation of Labor, the most powerful representative body in the United States — composing the great majority of organized workers, had perhaps 200,000 members. In 1910 the Federation had upward of 1,800,000, and in 1918 their membership totals a full 2,500,000. There are about 500,000 unaffiliated union workers.

The growth of trade-unionism in America is due in large part to the trust and combination movements of capital, and the many strikes in every trade, many of which were so successful that the workingman got a revelation of the power of organization, and the membership of some of the trades — the building and mining in particular — increased with leaps and bounds.

The Necessity for Labor Unions, as Illustrated in the Building Trades.— Great construction companies, wholesale employers of labor in the building trade, have been at war since 1899 more or less incessantly with the trade-unions. Strikes, lockouts and boycotts have been common in all the larger cities. Since 1901 the building industry has involved in the United States an annual outlay of something like $400,000,000 and employs more than 1,000,000 men. The experiences of the building trades in 1904 and the printing trades in 1906 demonstrated to the workmen the necessity for trades unions operating together, and this is now the fixed policy, accomplished through the American Federation of Labor.

Demands of Labor.— The demands of the American Federation of Labor made in resolutions will show what is sought by the American trade-unionists. These were:

1. Compulsory education.
2. The repeal of all conspiracy and penal laws affecting seamen and other workmen, incorporated in the Federal and State laws of the United States.
3. A legal work day of not more than eight hours.
4. Sanitary inspection of workshops, mines and homes.
5. Liability of employers for injury to health, body and life.
6. The abolition of the contract system in all public works.
7. The abolition of the sweating system.
8. The municipal ownership of street cars, waterworks and gas and electric plants for the distribution of heat, light and power.
9. The nationalization of telegraphs, telephones, railways and mines.
10. The abolition of the monopoly system of land holding and the substitution therefor of the title of occupancy only.
11. Direct legislation and the principle of referendum in all legislation.
12. The abolition of the monopoly privilege of issuing money and substituting therefor a system of direct issuance to and by the people.

The trade-unions of the United States are usually willing to resort to conciliation in the adjustment of differences as they arise, such conciliation to consist of committees representing each side and with equal power. They are usually in favor of arbitration when all means of conciliation have been exhausted, but they are opposed to compulsory arbitration, so called, and usually to compulsory investigation of the conditions attending a controversy. They do not object to although they have little faith in State boards of arbitration or other perfunctory legislative methods of adjusting difficulties. They are in favor of strict legislation relative to blacklisting. They claim that the blacklist is a rank injustice, and that wherever practised there is a degradation of the man blacklisted, and an annoying and irritating influence upon those who are not; that it is a menace to the well-being of labor everywhere. On the other hand, they do not hesitate to use the boycott in enforcing their demands, on the ground that it is a legitimate war measure against men who are considered as strike-breakers and thus traitors to the cause of labor. They insist that during periods of labor strikes or other controversies no man or body of men should be enjoined to prevent the doing of something which, if done, would be punishable under the criminal code; that they should not be debarred by injunction from picketing or patrolling, so-called, or from representing to non-union men that they had better not enter the service of the employer involved in a strike. They recognize their duty to avoid physical violence or intimidation, but claim that if some indulge in this, only those men engaged should be dealt with under the law. They insist that if they violate the law, and are thus amenable to punishment under it, they should not be subject to fines and imprisonment for contempt of court under an injunction; and they claim that all petitions for injunction should first be heard, either by a jury or otherwise, before they are subject to the process of contempt. They are not in favor of socialistic revolution; but that under the present industrial system their affairs can be adjusted, their claims fairly adjusted and their condition made reasonably satisfactory. They are, as a rule, in favor of the extension of State control in certain directions, but they are not social democrats as distinguished from State Socialists. They claim that the chief force which is extending State-socialistic doctrines comes from employers, through trusts and combinations and the aggregation of capital. They are, therefore, generally in favor of some regulation of fortunes and incomes, and the heavy taxation of incomes on some progressive principle. For statistics of labor troubles see STRIKES AND LOCKOUTS.

Bibliography.— For a general consideration of trades unionism and labor problems, consult Tolstoi, 'The Slavery of Our Times' (1900); Ghent, William James, 'Our Benevolent Feudalism' (1902); Brooks, John Graham, 'The Social Unrest' (1903); Mitchell, 'Organized Labor' (1903); Chapman, 'Work and Wages' (1904); Waring, 'The Law and Gospel of Labor' (1907); Smith, Samuel G., 'The Industrial Conflict' (1907); Gompers, Samuel, 'Labor in Europe and America' (1910); Carlton, Frank Tracy, 'The History and Problems of Organized Labor' (1911); Rogers, 'Six Centuries of Work and Wages' (1913); Fridon, 'New Unionism' (1913); Watney and Little, 'Industrial Warfare' (1913); Hobhouse, 'The

Labor Movement' (1917), and publications of the American Association for Labor Legislation. Also 'American Labor Year Book' (New York ann.), which contains many facts not often seen in the newspapers.

UNIONTOWN, Pa., borough, county-seat of Fayette County, on three branches of the Pennsylvania and one branch of the Baltimore and Ohio Railroad, about 70 miles south of Pittsburgh in the southwestern part of the State. It was settled in 1768 by Henry Beeson, and it was first called Beesontown. It was incorporated in 1796. Uniontown is in an agricultural region, but the county is noted for its extensive annual output of coke. In the vicinity are coal fields, deposits of iron ore, glass, sand and natural gas. The chief manufacturing establishments are glass plants, two foundries, brick yards, planing mills, flour mills and machine shops and coke plants. There are several churches. The principal public buildings are the Uniontown Hospital, county courthouse, jail, County Home for the Poor and the schools and churches. The educational institutions are a high school and public elementary schools. The banks have a combined capital of over $350,000, with deposits amounting to over $3,693,770. Two trust companies have a combined capital of about $300,000 and deposits of over $589,290. The government is on the commission plan. The net funded debt is $300,000 and the total realty valuation is placed at $8,000,000, which is one-third of the market value. The tax-rate per $100 of assessed valuation is $1.35. Pop. 20,000.

UNIONVILLE, Mo., town, county-seat of Putnam County, on the Chicago, Burlington and Kansas City Railroad, about 140 miles, in direct line, north by west of Jefferson City. It is in an agricultural and stock-raising region and in the vicinity are large coal-mines. The industries are chiefly connected with farm products and mining. The educational institutions are the public graded schools, one private school and a school library. Pop. 2,200.

UNIT. See UNITS OF MEASUREMENT.

UNIT SOCIAL ORGANIZATION, a sociological experiment which aims to bring all the people into a more active, intelligent and continuous participation in their own affairs, to vitalize municipal government and bring it closer to the lives of the people. The movement for this social plan was born in New York in 1916 and soon spread westward. The National Social Unit Organization advertised in 1916 for a community of 15,000 people somewhere in the United States which would be willing to try out its plan. Sixteen cities responded favorably, and Cincinnati, with well-federated social activities, a fine municipal university and with one of the best general hospitals in the United States, was chosen. The Mohawk-Brighton district of Cincinnati, a section populated largely by a native-born working class of Americans of skilled occupations, was selected as the experimental laboratory there. The original plan called for an experiment of three years, at the end of which time the work done was to be evaluated and a decision reached as to its extension. As it worked out in the Mohawk-Brighton district, two fundamental ideas of organization are involved. First, for the purpose of procuring the constant, active supervision of 100 per cent of the people over community affairs and also for the purpose of procuring representation by persons who actually know the people they represent. A block organization was formed consisting of a block committee, or council of seven, elected by preferential ballot by all the men and women in the block more than 18 years old, who in turn selected the block worker or block executive who sits on a central citizens' committee and forms one-half of the neighborhood administration.

Groups were organized from the community, physicians to plan for public health, nurses to plan nursing, recreation workers to study and plan for the community's play needs, the trade unions to report the workingman's point of view in the solution of neighborhood problems, business men to assist in the neighborhood business administration and teachers to plan a program of neighborhood education. Gifford Pinchot was chosen chairman of the National Citizens' Council of the Social Unit Organization. The social unit promoters have a distinct theory of unit organization, and their whole attitude toward its application is experimental. Having successfully applied the principles of organization for three years in one district, they are preparing to extend on a city-wide basis only those parts of the plan whose results have been demonstrated as beneficial.

UNITARIANISM. The Name.— So far as is known the name Unitarian originated in Hungary. It was used there at first as the title of an association of religious believers of various sorts in the year 1568 or thereabouts. Peter Bod, the Transylvanian historian, who was too bitterly prejudiced against the doctrines constituting Unitarianism to make his statements concerning it always trustworthy, relates that in 1557 the Diet of Thorda in Transylvania passed an edict (ratified in 1563) granting universal freedom of worship. At about the same time the various religious bodies within the country formed a league of toleration pledging themselves not to persecute one another. The members of this league were popularly called «The United» or «Unitarians.» So at first the title carried no sort of theological significance whatever. Embracing as it did all kinds of Christian believers, it indicated simply a fraternal relationship. This league, or union of fraternity and tolerance, did not long endure. Dissensions arising from more or less sharp differences of belief resulted in the withdrawal of those who held that belief in the dogma of the Trinity was fundamental to Christian faith and not to believe it an almost unpardonable sin. This withdrawal emphasized the Trinitarianism of those who withdrew and the lack of it in those who remained loyal to the league. These latter were the non-trinitarians, perhaps anti-trinitarians, believing in God as One instead of «God in Three Persons.» They were called Unitarians, however, not because of this belief, but because they still remained members of the league of «The United» or «Unitarians.» It was natural and unavoidable that the title should come at last to mark the distinguishing faith of those persons who remained loyal to the league. While «no confirmation of this can be found from Unitarian sources» Bod's explanation is probably not far wrong. Un-

less something of this sort had happened it is more than likely that the belief that "God is One" would have at that time been called by the distinctly theological term "Arianism." What is certain, however, is that the name Unitarian appears in the decree of the Transylvania Diet at Léczfalva, 25 Oct. 1600. Thirty-eight years later the name was ratified by Transylvania Unitarians as the official designation of their churches. It may well be assumed, in the absence of contrary testimony, that this name was chosen as the official designation instead of the purely theological term Arian because of the meaning it had when used as the name of the league of fraternity and tolerance. Although since then it has come to have a distinctly theological significance, and is to-day generally used to distinguish those persons and churches within Christianity who stand for simple monotheism from those who hold the Trinitarian formula, yet this early non-theological meaning of the name does best express the meaning which most Unitarians to-day give it.

History.— Unitarianism, that is the faith of those in Transylvania who in 1600 accepted the name as the official designation of their churches, and of those who since and in other countries have adopted the name or had it applied to them, may be said to be a belief that "God is One." The most conspicuous point of departure from Trinitarianism, the point usually emphasized, is the refusal to regard Jesus as "very God of very God" and the assertion that he was distinctly and unqualifiedly a human being. This belief in some form and of varying degree "has accompanied Christianity from the beginning, at least as one of its forms." Tertullian (circa 200), the first to introduce the term Trinitas into Christianity, is authority for the statement that in his day "the common people think of Christ as a man." It is usually conceded that even though it might not be correct to speak of Christianity during the first two or three centuries as being substantially Unitarian, it at least was not Trinitarian. It was this generally held belief that Christ was a man that Arius was trying to save in his conflict with Athanasius. It was this championship of Arius, of the human side of Jesus, that for centuries gave the name Arianism to any belief in the humanity of Jesus. But as the Arians expressed their belief in the great theological controversy that was had at Nicea (325), the difference between them and the Trinitarians was not very marked. The latter insisted that Jesus Christ was "of one substance" with the Father, the Arians refusing to go further than to concede that the Son was "of like substance" with the Father. Although the decision at Nicea was against the Arian view, faith in the simple humanity of Jesus persisted all through the centuries, and those who held this view were usually subjected to bitter persecution. Differing interpretations of the Trinity were the cause of frequent disturbances within the Church from the time of Arius but it is not until the upheaval occasioned by the Reformation of the 16th century that really serious anti-trinitarian opinion and propaganda are met with. So rapidly did these opinions gather force and win considerable following that the "reformers" no less than the Roman Church found it necessary to take measures against them. According to the temper and civilization of the times such measures were not marked by gentleness or humanity. Anti-Trinitarian opinions were, however, nourished rather than suppressed by persecution.

The burning of Servetus (1553) at the stake in Geneva, at the direct instigation of Calvin, for the sin of writing and publishing (1531) the book 'Errors of the Trinity' (Calvin's copy is one of the two or three copies of this book surviving) may be said to mark the beginning of Unitarianism as a definite and continuous movement. But Michael Servetus was not the first to suffer martyrdom for disbelief in the Trinity. Bishop Mant in his 'History of Ireland' records that in 1326 at Dublin one "Adam Duff was burned alive for his denial of the Trinity." In 1551 George Van Parris was burned for a like offense. Before Servetus there were others who had written against the Trinity; among these may be mentioned Martin Cellarius (1499–1564), a close friend of Luther, and Ludwig Haetzer, whose views, however, were not disclosed until after his execution (1529) for anabaptism. But it was Servetus who first put the issue squarely before the world. "Your trinity," he writes, "is a product of subtlety and madness. The Gospel knows nothing of it. The old Fathers are strangers to these vain distinctions. It is from the school of the Greek Sophists, that you, Athanasius, prince of tritheists, have borrowed it."

In Poland and Hungary.— A group of men in Italy had incurred displeasure because of their more or less outspoken opposition to belief in the Trinity, and they concluded it was the part of wisdom to move to other countries. Among these were Lelio Socinus and his uncle, Faustus, and Giorgio Blandrata or Biandrata. The greatest degree of freedom of religious thought was to be found at this time in the countries of Poland and Hungary. Considerable anti-trinitarian preaching was going on there. In Poland the names of Gonesius and Gregory Pauli are the most noted, and in Transylvania Bishop Francis David. With the coming of Blandrata, a physician, to Poland in 1558, "the spirit of Unitarian dissent entered upon a career of marked activity and success." In 1565 "a division of Polish Protestants took place, resulting in the establishing at that time of a Unitarian church." Fourteen years later (1579) Faustus Socinus (Zozzini) took up his residence at Cracow, and under his leadership the Unitarians, or, as they were more popularly known, Socinians, became a numerous and powerful body, "distinguished by the rank of their adherents, the ability and learning of their scholars, the excellence of their schools, and the superiority and wide circulation of their theological literature." Racow was their theological and educational centre. Here was published the Racovian Catechism — the first Unitarian catechism — in the Polish language in 1605. In 1608 it was issued in the German language and in the Latin in 1609. In the preface to a later and revised edition of this catechism the Unitarian attitude and spirit of this period are reflected in the remark, "we think we need not blush if our Church continues to make progress in some matters." A few years after the death of Socinus (1604) the Catholic reaction made itself felt. Unitarian churches and schools and printing estab-

lishments were gradually closed and confiscated, and in 1658 all adherents of "the Arian and Anabaptist sect were commanded to quit the kingdom within two years." Thus ended organized Unitarianism in Poland.

In the neighboring kingdom of Transylvania (Hungary) the Unitarian movement ran a somewhat similar course, except there it was not wholly destroyed by the Catholic reaction. There is some dispute as to the actual founder of Unitarianism in this country. Blandrata — who later was instrumental in starting the persecution of Unitarians when for purely personal reasons he sought to return to the Catholic Church — in 1563 came from Poland to Transylvania and "was made physician-in-ordinary to the king, John Sigismund"; and it is assumed that "through his influence the king, the king's mother, and many nobles accepted the Unitarian faith." Francis David, "now regarded as the true apostle of Transylvania Unitarianism," was elected (1564) bishop of the Calvinistic churches. His liberal and eloquent preaching attracted multitudes in Klausenberg, and caught the attention of Blandrata, who used his good offices to have him appointed chaplain to the king in 1566. Here he preached the doctrine that "he who divided Christ into two, man and not man but God, he is a deceiver." In 1568 was issued a royal edict, confirmed by the Diet, giving to everyone complete freedom of conscience and of speech. During this year a great public debate was held with David and Peter Melius, a strict Calvinist, as the chief debaters. David triumphed and that "day the whole people of the town of Kolozsvar became Unitarian," which is probably an exaggeration but plainly reveals the power of David's preaching. "The example was followed by a large number of Transylvania towns." At about this time there were in this country 425 congregations Unitarian by profession. "In 13 higher schools and colleges besides that doctrine was taught by able professors, several of whom were refugees from other lands." By 1578 a serious controversy developed within the Unitarian churches. Blandrata, who was preparing to save himself in the powerful Catholic reaction which he saw coming, headed the party who were for maintaining that "Christ should be invoked with divine honors, though without any inherent title to such homage," and he called to his aid Faustus Socinus, who was a noted champion of this idea. The result was a "public explosion on David's part against the cultus of Christ in any shape or form." Whereupon, at the instigation of Blandrata, articles were drawn up "accusing David of innovation of doctrine," and presented to the Roman Catholic king then reigning. The accused was condemned to imprisonment for life. "Five months later (1579) he died in the dungeon at Deva." Despite the confiscation of their schools and churches and printing establishments which followed, the Unitarians maintained their existence and with the enactment of a statute in 1791 granting "equal liberties and rights in Transylvania" a new day dawned for these churches. To-day there are 116 churches with a total membership of 80,000. These churches are presided over by Bishop Joseph Ferencz, a bishop being made necessary by the laws of the country.

England.— The organized beginnings of Unitarianism in England may be said to date from about 1773, when Theophilus Lindsey, on the failure of the petition for relieving clergymen "from the burden of subscribing to the thirty-nine articles," resigned his "living in Yorkshire and gathered the first professedly Unitarian church in London." Prior to this time, however, there was considerable anti-trinitarian sentiment. From 1551 to 1612 no less than nine persons suffered martyrdom on this account. In 1614 a Latin version of the Racovian catechism was publicly burned in London. Such treatment did not avail to stop the spread of this sentiment as is evident from an ordinance passed in 1648 making denial of the Trinity a capital offense. This ordinance was rendered inoperative by Oliver Cromwell, who refused to sanction the prosecution of Paul Best and John Biddle. The latter occasionally, from 1652 to 1662, held a "Socinian conventicle in London" and published much Unitarian or Socinian literature. In 1655 the great Dr. Owen complained that "there is not a city, a town, or scarce a village in England where some of this poison is not poured forth," and the Act of Toleration (1689) specifically excluded papists and deniers of the Trinity. Thomas Emlyn, fined and imprisoned (1703) in Dublin for rejecting the deity of Christ, preached Unitarianism in London in 1705. William Robertson in Ireland — sometimes called the father of Unitarian non-conformity — seceded from the Established Church at a date earlier than Lindsey. The scholarly Nathaniel Lardner in 1730 advocated in his writings a purely humanitarian view of the Christ, as did also Dr. Joseph Priestly in 1767. A century before this John Milton taught a similar gospel in his 'Christian Doctrine.' Isaac Newton was an anonymous writer on the same doctrine and John Locke in his 'Reasonableness of Christianity' (1695) ranged himself on the same side. Dr. Samuel Clarke, Isaac Watts and Phillip Doddridge aided materially in the spread of "Socinian and Arian views among dissenters." When Dr. Lindsey withdrew from the Established Church and set up a Unitarian meeting-house in London, a number of ministers of Presbyterian chapels soon followed his example. In the case of these latter it was not necessary for the ministers to withdraw from the ministry of these institutions because the chapel trust deeds gave freedom of theological opinion, so there was nothing to prevent the chapels from accepting the Unitarian views. Thus it came to pass that a number of chapels with open trust deeds bodily went over to the Unitarian movement inaugurated by Dr. Lindsey.

In 1791 the Unitarian Book Society for the distribution of literature was organized, and from then on Unitarianism becomes a definitely organized force in the religious life of England. In 1844 all civil disabilities which Unitarians had suffered were removed.

At present there are in Great Britain 370 places of Unitarian worship. The number of members is not known and estimates are useless. Manchester College, Oxford; The Unitarian Home Missionary College, Manchester; and Presbyterian College, Carmarthen, Wales, are the training schools for British Unitarian ministers. The British and Foreign

Unitarian Association, with headquarters at Essex Hall, Essex street, London, is the organization through which missionary and denominational enterprises are carried on. *The Christian Life* and *The Inquirer*, London, are the leading denominational periodicals.

America.— It would not be correct to assume that Unitarianism in America, which appears subsequent to its organized existence in Europe, originated independent of all foreign influence. The intercourse between the people of the Old World and the New made that impossible. Besides, the migration of people from the older countries to America in search sometimes of a greater freedom naturally included some of the Unitarian way of thinking and believing. The most notable and influencing single incident was the coming of Dr. Joseph Priestly to the United States in 1794. Two Unitarian churches were founded by him, Northumberland, Pa. (1794), and Philadelphia (1796). The Unitarian church (1803) at Oldenbarnveld, later Trenton, now Barneveld, N. Y., was founded by a group of Dutch refugees who had close relationship with the English Unitarians. These three churches have played a considerable part in the spread of Unitarianism in America, and the church at Barneveld furnished the inspiration to Mr. Huidekoper who later founded the theological school at Meadville, Pa.

But, broadly speaking, American Unitarianism is of American origin. It is in part the fruit of the spirit of religious freedom embodied in the *Mayflower* compact, and in part the result of the democratic form of government which ruled the New England parish churches. It is a suggestive and significant fact that the oldest Pilgrim church in America, that founded at Plymouth in 1620, in 1801 declared itself to be Unitarian by a large majority vote, and this without making any change whatever in its covenant. This church, now Unitarian in name and fellowship, uses the identical statement of faith drawn up by its Pilgrim founders. American Unitarianism is in large part the product of the habit of many notable New England divines of thinking and speaking their own thoughts and of their utter dislike of anything that savored of monarchy in religion as well as in politics. It was also a product in part of their rebellion against what seemed to them to be the moral defects of the popular faith.

Before 1825, the date usually adopted as the beginning of organized Unitarianism in the United States, the ideas peculiar to Unitarianism were being preached by an ever-increasing number of the New England clergy and laity. It is not possible within the space of this article to trace these beginnings. To Jonathan Mayhew, settled as minister of the West Church in 1747, belongs the honor of being the "first outspoken Unitarian in New England, not merely because he rejected the doctrine of the Trinity, but because he accepted all the cardinal principles developed by that movement since his day." More important, in some respects, was the action of the corporate body of King's Chapel, Boston — the first Episcopal church in New England — declaring for Unitarianism by inviting (1782) Rev. James Freeman to become its minister, and three years later voting to revise its Episcopal ritual by eliminating all Trinitarianism therefrom. During the last decade of the 18th century Unitarianism is reported to be "on the increase in the Southern counties of Massachusetts" and that "it is on the increase in Maine," but with the exception of King's Chapel and temporary societies in Portland and Saco, Me. (1792), the churches established at Northumberland (1794) and Philadelphia, Pa. (1796), there was nothing in the way of organized Unitarianism before the opening of the 19th century.

The next important incident after the action of King's Chapel was the outcome of a controversy within the old church at Plymouth. In 1799 the church and parish, voting separately as was the custom, chose the Rev. James Kendall as minister. The minority, opposed to the liberal or Unitarian views of Dr. Kendall, withdrew from the old church and established the church known as the "Church of the Pilgrimage," leaving the church of Brewster and Robinson to become one of the pioneer churches in the Unitarian movement. Thus far the movement had gone along without creating anything more than local dissensions. But signs rapidly multiplied of the coming storm which was to rend New England Congregationalism into Orthodox and Unitarian. With the opening of the 19th century the clergy of the stricter sort were writing and speaking more critically and impatiently of the unorthodoxy that was being preached by a considerable number of eminent clergy. In one instance it went further than critical words. The Rev. John Sherman (grandson of Roger Sherman), minister of the First Church, Mansfield, Conn., was expelled (1805) from the Windham County Ministerial Association for his anti-trinitarianism. In his defense he published the first anti-trinitarian pamphlet on this side of the Atlantic, the title of which was "One God in One Person Only." The election of the Rev. Henry Ware, known as a Unitarian, as Hollis professor of divinity at Harvard College, was the signal for controversy and open strife to begin. Immediately a war of pamphlets and sermons and periodicals was on and separation came to be ever more and more inevitable. The stricter brethren widened the breach by establishing in 1808 a theological school at Andover to train clergy free from taint of the Unitarian heresy. The men charged with this heresy steadily denied that they were Unitarians or had any desire or purpose of being such, but in 1812 Dr. Belsham of England published his life of Theophilus Lindsey and in it he included a chapter on American Unitarianism which revealed a "much closer alliance of several Boston liberals with the movement in England than they had been supposed willing to admit." In 1815 Dr. Jedidiah Morse saw the volume and forthwith gave wide publicity to the facts. He went further and in his periodical, *The Panoplist*, virtually charged the exponents of Unitarian ideas in New England with being afraid to come out in the open and acknowledge the real character of their teachings. Whatever the merits of the accusation — and the accusation is not without prejudice — it forced the controversy to a crisis which eventually resulted in the severance of New England Congregationalism into "Orthodox" and "Unitarian" by the withdrawal in many cases from the old parish churches of

the orthodox party, leaving those of Unitarian ways of thinking in charge of the old church properties and organization. This seems to suggest, what is further borne out by an examination of the early New England church covenants, that the Unitarian movement in New England and consequently in America was not a secession from Congregationalism but a development of the principles upon which it was founded.

The men charged with heresy did not hesitate to show their colors. Such men as William Ellery Channing settled over the Federal Street Church in Boston in 1813; Edward Everett, who became minister of the church in Brattle street in 1814; Francis Parkman settled at the New North Church 1812 and others met the charges and criticisms by a more definite and outspoken presentation of the things they held to be true. Their position is not correctly described as being mainly anti-trinitarian. They virtually called in question the whole doctrinal structure of orthodoxy. This was made clear by Dr. Channing in the sermon — now a historic landmark in Unitarianism — preached at the ordination of Jared Sparks in Baltimore, Md., in 1819. Dr. Channing used this occasion "to give a distinct statement of the opinions generally held by his liberal brethren,— their mode of interpreting the Scriptures, their views concerning God and Christ, their idea of the nature of his mission and mediation." This sermon marks the parting of the ways. The following year, overcoming their repugnance to even appear to favor organizing another religious body, the "liberal" ministers organized the Berry Street Conference for discussion among themselves. Five years later (1825) "a club of some 25 liberal-minded and public-spirited citizens organized for social and philanthropic purposes," which had existed in Boston for some years, at a meeting held at the residence of Hon. Josiah Quincy, discussed "the advisability of forming an association to publish books and tracts setting forth the opinions and principles of the liberal party in the Congregational churches." The outcome was the forming, on 25 May 1825, of "a new society to be called the American Unitarian Association." By a chance coincidence the British and Foreign Unitarian Association was organized on the same day. Henceforth Unitarianism is recognized as one of the religious bodies of America.

In America, as elsewhere, Unitarianism has experienced many conflicts within itself. The old order of things, the old thoughts were continually being challenged. In the early years Unitarians retained much supernaturalism in their belief and forms of worship as is seen in the fact that Ralph Waldo Emerson felt under the necessity of resigning as minister of the Second Church in Boston because the church refused to "discontinue or radically change the order of communion service." It became more and more clear that the genius of Unitarianism was fundamentally out of harmony with traditional and popular Christianity. This, for the first time, was most conspicuously evident when, in July of 1838, Mr. Emerson addressed the graduating class of Harvard Divinity School. This address, on account of its unusually frank criticism of the traditional views of the "Divine Nature, Jesus, Christianity and of the offices of the church," started a controversy within Unitarianism which was destined not to end until the "traditional" views were practically eliminated. Great impetus was added to this controversy and a division seemed to threaten, when Theodore Parker spoke on "the transient and permanent in Christianity" on 19 May 1841. This was further expounded in the following winter in a series of five lectures which he published under the title of a 'Discourse of Matters Pertaining to Religion' So acrimonious became the discussion that many of Parker's fellow Unitarian ministers hesitated to call him a Christian. The central principle of Unitarianism which from the first had been the right of private interpretation and freedom of speech was strong enough, however, to prevent any serious rupture. A few years later the right of a man to think his own thoughts and to speak them in religious matters became something of an issue through the attitude of the American Unitarian Association toward Theodore Parker. His frank departure from traditional beliefs and customs prompted the more conservative members of the denomination to scrutinize closely the beliefs of the young men coming into the ministry, and to create an atmosphere uncomfortable to too advanced thinkers. The men of the Middle West, while not taking sides in the doctrinal controversy which Emerson and Parker had precipitated, felt there was a distinct menace to freedom of thought and expression in the attitude taken toward Dr. Parker, and so when these men of the Middle West organized in 1852 the Western Conference they were stoutly resolved to preserve the right of men to think and speak as they believed. In the following year, in giving advice to the missionaries of the conference, it was stated that under no circumstances should they require "subscription to any human creed, or the wearing of any distinctive name." With the denominational reawakening which came after the Civil War the question of the basis of fellowship became an issue. In 1865 the National, now the General Conference of Unitarian and Other Christian Churches, meeting biennially, was organized and the basis of fellowship although very broad was considered too narrow by some of the more radical, who thereupon organized the Free Religious Association. These conflicts came to an end by the action (1894) of the National Conference in adopting the present preamble to the constitution of that body. That is, Unitarians decided once and for all that within organized Unitarianism there should be absolute freedom of thought and expression. The constitution of the General Conference reads: "These churches accept the religion of Jesus holding, in accordance with his teaching, that practical religion is summed up in love to God and love to man . . . we cordially invite to our working fellowship any who, while differing from us in belief, are in general sympathy with our spirit and practical aims." With this jealous insistence upon freedom of thought and speech for every individual, Unitarianism, or rather the Unitarian churches, have gone along associating themselves together in an increasingly effective organization. Lacking a central authority to compel obedience the Unitarian body lacks the driving power essential

to conspicuously successful propaganda. Unitarianism can only appeal to those who are thinking in its direction.

The character and aim of the organized activities of the denomination are evidenced by the various departments into which the American Unitarian Association (Boston, Mass.), the executive branch of the denomination, is divided. The publication department, besides printing and publishing books of a more or less denominational character, aids in the work of Unitarian propaganda by printing and distributing tracts to the number of about 400,000 copies annually, while the publicity department "has for its special work the diffusion of Unitarian principles through the medium of the press." The department of comity and fellowship "has jurisdiction over matters connected with interdenominational interests and seeks to substitute co-operation for competitive methods in church work." There is also a department of church extension and a department of community service. The latter aims "to promote in the churches a study of social problems," and "to cultivate closer and more sympathetic relations between the churches and the wage earners." The committee on new Americans is engaged in missionary work and establishing churches among Americans of foreign birth and speech. The department of religious education seeks "to correlate and vitalize the endeavors of the denominational Sunday schools." It issues manuals and lesson helps, conducts Sunday school institutes, provides lecture courses for teachers and aims to introduce and encourage modern methods in religious education in the Unitarian churches. There is a department of foreign relations, not foreign missions. The following quotation expresses the denominational attitude: "Foreign missions have never commanded a general interest on the part of Unitarians. Their dislike of the proselyting spirit, their intense love of liberty for others as well as themselves, and the absence of sectarian feeling have combined to make them, as a body, indifferent to the propagation of their faith in other countries. They have done something, however, to express their sympathy with those of kindred faith in foreign lands." As early as 1824 the Unitarians of America took a lively interest in the Hindoo leader Rammohun Roy, who had "adopted Unitarianism," and also in the work of the Rev. William Adam, a Baptist missionary, who had become converted to Unitarianism in India and in 1826 joined with the English Unitarians in a plan to send a sum of money yearly to aid the work there of the British Indian Unitarian Association. In 1853 the Rev. Charles H. A. Dall was sent from this country to Calcutta, where he devoted himself to the work of education rather than of preaching. He founded the Calcutta School of Industrial Art, the Useful Arts' School, the Hindoo Girls' School as well as a school for the waifs of the streets. "His influence was especially felt in the education of girls and in industrial training, in both of which directions he was a pioneer." Since the death of Mr. Dall the aid given India has been through the natives themselves, particularly through the Brahmo-Somaj, which has societies and houses of prayer all over India, and is engaged in religious, educational and reformatory work. In 1884 Yukichi Fukuzawa started a movement in his country, Japan, looking "to the introduction of a rational Christianity." In response to an urgent request from Japanese the Rev. Arthur M. Knapp was sent to Japan in 1889 to investigate, and later in that year Mr. Knapp was prepared to begin work. In defining the purpose of his mission Mr. Knapp said, "receive us not as theological propagandists, but as messengers of the new gospel of human brotherhood in the religion of man." The work of Mr. Knapp and his colleagues was wholly educational. "No churches were organized by the representative of the American Unitarian Association. Those that have come into existence have been wholly at the initiative of the natives themselves." In 1896 was organized the Japanese Unitarian Association, which, through the co-operation of influential and scholarly Japanese, is helping to liberalize religious thought throughout the country in both the Buddhist and Christian communions. In Italy the Unitarian work is carried on by the Association of Free Believers. A Unitarian association has been organized in Brazil by Brazilians, and movements Unitarian in everything but name are to be found in Switzerland, Holland, Norway and Denmark. There are Unitarian churches in the English-speaking countries, South Africa, Australia and New Zealand.

In the United States and Canada to-day there are about 475 churches and missions. Although the census of the membership of these churches is given in various publications, as a matter of fact there is no official census of Unitarian membership. This is due to the fact that usually Unitarian ministers have little interest in church membership. Unitarian ministers are educated at the divinity school of Harvard University, which school "was founded and endowed by Unitarians"; the Meadville Theological School, Meadville, Pa.; the Pacific Unitarian school for the Ministry, Berkeley, Cal. The *Christian Register; Unitarian Word and Work*, Boston, Mass., are the leading denominational periodicals.

What Unitarians Believe.— Popularly a Unitarian is one who does not believe in "the divinity of Christ," or more correctly in the deity of Christ. That is but another way of saying that Unitarians do not believe in the Tritarian formula expressed in the Athanasian and Nicean creeds and embodied in all Protestant orthodox creeds. Because of this lack of belief in the Trinity, Unitarians are classified in the United States Religious Census as "non-evangelical," and are usually officially classified by the "Evangelical" bodies as non-Christian. This latter classification was very definitely made at the organization of the Federation of the Christian Churches of America in 1905. This officially representative body of "Evangelical" churches decided that to qualify as a "Christian" church there must be a complete acceptance of the Trinitarian formula. Unitarians decline to accept that decision and emphatically insist that it is not necessary to be a Trinitarian in order to be a Christian. To support this contention they point out that, so far as is known, Jesus himself did not teach the doctrine of the Trinity, neither did the Apostles. The only passage in New Testament literature which in any way reflects or embodies the Trinitarian

formula is that in 1 John v, 7, so plainly an interpolation that it is dropped from the Revised Version without any comment. Thev also point out that it was at least 150 years after the crucifixion of Jesus before the term Trinity began to be used by Christian teachers, and it was considerably later than this before the Trinitarian formula was decided on as the Christian conception of deity. Unitarians hold that this doctrine, instead of coming from anything Jesus or the Apostles or their immediate successors taught, is altogether of heathen origin, though this is not necessarily anything against it. So they argue that in rejecting the Trinitarian formula and insisting on a pure monotheism they follow much more closely the teachings of Jesus than do the Trinitarians. For this reason they insist that they are entitled to be regarded as Christian. However, Unitarians care little for a *name*. The important thing is to be Christian in spirit. They always speak of themselves as Christians. "But," as Dr. Lowe expressed it when the wisdom of adopting the name as a part of the official title of the national organization was being thoroughly debated, "I will oppose, as a test (of fellowship), any *definition* of Christianity." That was designed to indicate that Unitarians regarded Christianity, not as a set of definitions of God and Christ, but rather the Christ spirit which a man is under obligation to put into his every day life.

Unitarians have no creed, no *official* theology. They have "statements" of faith, The most popular being: "The Fatherhood of God; the Brotherhood of man; the Leadership of Jesus; salvation by character; the progress of mankind onward and upward forever."

But this is in no sense final or authoritative, it is simply an attempt to set forth the things most commonly believed. There are forms for admission into Unitarian church-membership, but in no case is any sort of doctrinal test imposed or implied. This arises not from any lack of religious belief or conviction among Unitarians, but, first, because they hold that belief in and frequent recital of a creed does not necessarily make a person Christian or even religious; secondly, guided by experience, Unitarians feel very strongly that no church or council ought or has any right to require any person to commit himself for all time to some particular form of worship, or sacraments or dogmas no matter how true they seem to be. They are not willing to accept as spiritual guides men who had so imperfect an understanding of the world they lived in as did the makers of Christian creeds. Believing in the spiritual imperfection of all persons and institutions, past as well as present, Unitarians feel that creeds and sacraments which change not make it impossible or unnecessarily difficult to press forward to a finer spiritual quality in life. Believing as they do that man is a progressively spiritual being in this world, they insist that the last word in religious truth has not been uttered and the goal of spiritual endeavor is still far ahead. For this reason Unitarians refuse to have anything to do with finalities and infallibilities in religion.

There is nevertheless a Unitarian faith which binds Unitarians together in a common purpose and a sort of common understanding of religious matters. It has been expressed thus: "Just as an association of scientists is constituted and sustained not by the adoption of a theory, however certain, but by a common purpose or aim, so a church is possible by virtue of the common purpose to seek contact with the divine life and to find mutual expression of the experience." Although Unitarians are free to formulate each his own conclusion there runs through all the consequent diversity of opinion strands of a common faith and on all great religious issues there is among them a quite strong agreement. There is space for only a few brief hints on this point.

Unitarians are verv modest when it comes to speaking of the Infinite Spirit "in whom we live and move and have our being." To believe in, to have a lively consciousness of God, they do not consider it needful to assume a detailed familiarity. They shrink from frequent repitition of the name and also from using any word or phrase that suggests an anthropomorphic conception. Unitarians most commonly speak of God as Father, not because that is an adequate or exact term, but because it suggests the finest, the most universal, the most unselfish elements a man can conceive of or aspire to. Perhaps the term is generally used by them because it suggests that this overshadowing, transfusing spirit is all the time prompting, tempting man to grow up into the divine likeness, just as the noblest of human fathers prompts his child to grow up in the likeness of the father's noblest self. Whether a distinct personality shall be ascribed to the idea of the Divine Fatherhood is a matter which each must decide for himself. They incline to the belief that a definite idea about God cannot be communicated from one to the other by a series of words or by a formula as is a law of science or a principle in mathematics, but that the idea must come from one's intuitive or acquired understanding. In thinking and speaking of God Unitarians are guided by the revelations of science no matter how recent, because they hold that if God is the living principle in things, that spirit which seems to be forever shaping the world of human life toward ever finer issues, then plainly a more accurate understanding of the Divine Spirit will come with every new discovery, every step toward the ultimate truth of things. Unitarians prefer to speak of their *thought of God* rather than of a *belief in God,* for the reason that the former phrase indicates that God is becoming more clearly revealed and that future generations will know more than is yet known concerning the Divine Spirit. While Unitarians do not believe it possible to express their thought or consciousness of God in a phrase there are two Biblical utterances which they frequently quote as expressing their idea. "Hear O Israel: the Lord our God is One Lord" (Deut. vi, 4) and "God is Spirit and they that worship Him must worship Him in spirit and in truth" (John iv, 24).

The Unitarian idea of Jesus is that he is in all respects a human being. They hold that the idea that Jesus was "a man and something more" makes his "life of singular purity, elevation, courage, sanity and devotion" worthless as an example to beings who are *only men.* Also a Christ "conceived of the Holy Ghost and born of the Virgin Mary" adds no distinction or force to anything Jesus said or did

or was. That idea simply makes him one of many mythological beings which form the centre of many religions. Unitarians contend that the Christ of miraculous birth is not the historical figure of the Gospels, but an imaginary being created by theologians, in the days when there was no knowledge of science or history, for the purpose of meeting the necessities of a very elaborate scheme of saving man from "the wrath to come." They insist, without any sort of reservation, that Jesus was an historical person; that he was the son of Joseph and Mary. This they set forth not as a dogma but as belief imposed upon them by such facts as are known. They point out that while there are great and irreconcilable differences between the two New Testament stories of Jesus' birth, the only two Gospel narratives that include these stories fully agree in regarding Jesus as the son of Joseph. Thus in the genealogies, Matt. i, 2-6 and Luke iii, 23 ff, the lineage of Jesus is traced through the male line, the author of Luke iii, 23, going so far as to say that Jesus "was, as people supposed, the son of Joseph." Then there is the testimony of Tertullian (cir. A.D. 200) that at that period "the common people think of Christ as a man." The Unitarians accept the verdict of history that Jesus was a man. They agree that he may have manifested an unusual degree of divinity or godlikeness — divinity as they understand it refers to the quality of a person's character and not to the nature of the body — that he may have possessed unusual spiritual gifts and psychical powers but they hold this does not warrant them in regarding him as being other than human. There is no disposition among Unitarians to take each and every idea ascribed by the Gospel writers to Jesus and attribute something like infallible authority to such ideas. It is less the words of Jesus than the spirit he put into all his deeds and relationships which they revere and accept as constituting the "leadership of Jesus." Unitarians hold that the abiding and growing influence of Jesus upon the world proceeds from the excellency of his manhood. His name is an increasing inspiration because he himself was man enough to stand for wonderfully fine ideals of life in this world and abated not one jot of his devotion to those ideals even when the cross was the penalty for such devotion. The popular idea that Jesus died on the cross as a divine sacrifice finds no place in Unitarian belief. He is Leader rather than Saviour. Instead of believing that by his death he opens the way to a heaven above they believe that the ethical principles according to which Jesus lived point the way whereby man may make this world heavenly. Because the life of Jesus was a *man's* life, his gospel a *man's* gospel, Unitarians insist that it is a gospel which every man can and ought to live.

Unitarians believe in salvation as a purely human act, involving only human powers, the results of which are effective in changing the character of a man's life here in this world. A salvation which aims to bring about a change in the sentence which a "supreme judge" has already pronounced against the soul of a man, a salvation which seeks to save one from terrible penalties inflicted for eternity beyond the tomb, does not appeal to Unitarians as being helpful or in accord with the facts. They reject the idea that sin is purely or primarily an offense against God. Sin is moral and not theological in its nature. They cannot see how there is any sin in a man's disbelieving any or all the doctrines embodied in the church creeds. It may be indefensible to refuse to belong to a church and to participate in the great sacraments, but they decline to regard this as a violation of the moral law. According to their idea sin is wrong more or less deliberately committed by one person against another. Any word or thought or sentiment or deed which in any way works against moral and spiritual well-being, that is sin. From this it follows that the first and only step which a person can take toward salvation is not merely to strive to right the wrong but to so change himself and his plan of life that he will henceforth do right and desire and plan only to do right. Consequently Unitarians cannot think of salvation as a means of escaping the consequences of sin. A man must accept the consequences of his words, of his thoughts, of his deeds. From this there is no possible escape and ought not to be. A man enters the path of salvation only when he refuses to do or think or speak evil. And this every man, in a greater or less degree, is capable of doing. Unitarians reject the prevalent belief that man is *unable* to save himself, and so must needs plead his helplessness before a great supernatural saviour. They hold that by a continual struggle to master temptations and provocations from within and without a man can, and in no other way can he, become a *saved* man. In their judgment salvation is seldom a completed act. Few if any are wholly saved. The degree of salvation which a person enjoys is the measure of his triumph over injustice, greed, hatred and the thousand and one evils which beset a man in the world. In so far as ritual acts or belief in supernatural influence spur a man to righteous endeavor such play a part in his salvation. There is, so Unitarians believe, the power of salvation within every person. Every effort which a person makes toward rightness of life is this saving power in operation. The purpose of salvation, as Unitarians conceive it, is not to secure a place in a heaven beyond, but to secure an ever-increasing measure of heaven-likeness here.

What Unitarians believe concerning the future can easily be inferred from this. The idea of a "heavenly city" above and a "bottomless pit" below is dismissed by them as without warrant of fact; it has not even symbolic value. They have a "great hope" of future existence, but they stop short of expressing any definite knowledge concerning the *what* or the *where* of such existence. They hold as a hope, with some it is quite a positive belief, that the future can be nothing other than a continuance of this life. Unitarians generally feel quite sure that whatever happens after death, the soul that has lived its years on earth in sin will not, as a reward for certain theological beliefs, enter into a state of perfect bliss and holiness, neither will such a soul because of lack of such beliefs enter into a pit or state of horror and despair from which there is no escape. There is no great gulf of difference

separating the future from the present. The soul passes on with all the character it has won on earth unchanged. The idea of a soul being sentenced eternally to happiness or misery is rejected by Unitarians as being utterly unjust. Death does not determine the soul's character for all eternity. Death is not doom. If the soul lives on it is the belief of Unitarians that its continued existence must be amid conditions which allow of unceasing progress toward perfection or constant deterioration, as each soul shall elect. In the *life that is to be* as well as in *the life that now is* the soul must reap what it sows. An eminent Unitarian scholar well expresses the general Unitarian attitude in these words: "The doctrine of immortality is one in which Unitarians do not take a very acute interest. Their respect for human nature — their conviction as to the imperativeness of the moral law, their profound faith in the goodness of the earthly life as a part of the goodness of all life rightly understood — all these combine to fix their attention rather on this life than on the life after death.

The manner of compiling the existing canon of the Bible coupled with the fact that the men engaged in the task did not know more than the scholars of to-day makes it impossible for Unitarians to accept the belief that this book is God's inspired and infallible Word. The fact that there are in other religions scriptures believed to be inspired by deity and infallible takes from the idea that the Bible is a sacred book whatever distinction and authority such an idea is supposed to possess. Unitarians, however, hold the Bible in high esteem. They treasure it as one of the great, perhaps the greatest of the religious books of the world. And though they concede that it speaks with authority on some matters it is only the authority of the man who sees clearly and speaks accurately. So an utterance which has authority in the Bible would have no less authority if found in any other book. Nor is a thing true or *more* true because it is in the Bible. Whether in the Bible or out of it a thing is true only to the degree that it squares with knowledge and experience. To Unitarians the Bible is an inspiration, never a finality. It is read from Unitarian pulpits partly from custom, but most of all because it contains many passages of surpassing ethical beauty and inspiration, and usually only such passages are read. They use it in their Sunday schools because it deals with the history of a great people, and largely because it discloses the sources and character of many religious, political, ritualistic and ethical ideas which have shaped and directed Christian civilization. But Unitarians never lose sight of the fact that the Bible is distinctly a Hebrew rather than a Christian production. But that fact does not detract from nor add to its ethical and spiritual excellencies. From these excellencies Unitarians will continue to draw ethical and spiritual encouragement and illumination.

The Church according to the Unitarian understanding of things is a purely human institution. With all due respect to its traditions and appreciative of the good it has helped man to achieve, and wholly mindful of what in the way of spiritual comfort and strength it has been and is to many, Unitarians cannot ignore what seem so plainly to them to be the facts that the Church within Christianity is comprised of a series of churches each maintaining a separate existence by the imposition of fairly definite rules of exclusion. The idea that some one Church is the one and only true church does not seem to be warranted. Nor does the idea that there is somewhere within, behind, above existing churches a sort of true, mystic church of the Spirit, which will some day be established, appeal to them as having any force of truth. The Church is simply an organization of man's religious interests. The institution, no matter what its traditions and claims and forms, can have no authority above that which proceeds naturally from the intellectual and spiritual attainments of the persons composing it. Like every other institution it has a right to require that those seeking admission shall go through certain forms and pass a satisfactory examination on matters of belief, but to offer eternal rewards or pronounce eternal doom is wholly beyond its right and power. To belong to a church cannot secure any one a privileged position after death. The Church is a saving and righteous force in a community when and only to the extent that its members are living examples of purest and noblest character.

The rites of Baptism and the Lord's Supper are observed in many Unitarian churches, but Unitarians do not retain the old belief in these matters. They attach no serious importance to them. The idea that immersion or sprinkling or signing with the cross with water upon adults or babes can effect any spiritual regeneration or in any way change the relation between a human being and deity is rejected. Ritual or Sacrament can, in their judgment, possess no saving power. In Unitarian practice "baptism" is generally spoken of as "consecration." The purpose of the service of consecration of children is to express the parents' desire that the children shall grow up into purity of life and nobility of service. The same idea is carried out in the consecration of those of "riper years." It is a consecration of life "to God and his truth and to the service of your fellowmen." The observance of the Lord's Supper is found only in the older Unitarian churches, and in these its observance tends to gradually disappear. Where it is most regularly observed the sacramental idea is wholly eliminated. The form is retained as is some of the old phraseology which conveys the ancient belief that the communicants are partaking of a sacrifice, but the idea is wholly foreign to Unitarian thought. What Unitarians have in mind is in the nature of a memorial service recalling the life of the Master. The tendency to abandon it altogether is due to the fact that it is exceedingly difficult to avoid being misunderstood. An ancient ritual is a poor medium through which to convey modern ideas. The idea that great spiritual merits are obtained by this or any sacrament is not accepted by Unitarians, but they believe that in so far as observing the Lord's Supper inspires a passionate love of the character and work of Jesus it is good.

The one purpose of real religion, Unitarians believe, is not to prepare people for another life, but to inspire them to live this

as it ought to be lived. This explains why Unitarians have been most conspicuous in all enterprises which aim to improve the general well-being, morally, intellectually and even materially. Thus it happens that in an unusually large number of instances Unitarians have been pioneers in philanthropic and educational enterprises and have been pre-eminent in literature. A few instances may be quoted. The founder of the Perkins Institute for the Blind in Boston, a pioneer movement, was Dr. Samuel G. Howe, and to Dorothea Dix must be given credit for starting the movement which resulted in a more humane treatment of those in prisons, in almshouses and hospitals for the insane. A Unitarian layman, Henry Bergh, was the founder of the Society for the Prevention of Cruelty to Animals. The first woman advocate of the "rights of women" in the United States, Margaret Fuller, was a Unitarian, and conspicuous in this movement have been such women as Julia Ward Howe, Elizabeth Cady Stanton and Susan B. Anthony, all of them Unitarians. Horace Mann, pioneer in educational reform, was a Unitarian layman, and Henry Barnard writes that "had it not been for Cyrus Peirce (Unitarian minister) I consider the cause of Normal schools would have failed or been postponed for an indefinite period." Peter Cooper, founder of Cooper Union in New York City, was an earnest Unitarian. The first library in the United States that was free to all the inhabitants of a town or city was opened in Dublin, N. H., by the Unitarian minister of that place, the Rev. L. W. Leonard; and in the adjoining town of Peterborough, under the leadership of the Unitarian minister, the Rev. Abiel Abbott, the people voted to tax themselves to maintain a library—the first library in the country supported from the tax rate of a municipality. The United States Sanitary Commission, which did such splendid service in the Civil War, was originated by the Rev. Henry W. Bellows, minister of the Unitarian Church of All Souls in New York City. This devotion to humanitarian work is not accidental, it is Unitarian religion, and in their churches emphasis has been and is always put upon the religion of service, making the most and the best of this life.

This goes to explain how it comes to pass that Unitarians have been so conspicuous in literature, statesmanship, in the judiciary and elsewhere. The Unitarian representation in literature is out of all proportion to the size of the denomination. In American literature Unitarians are represented by Henry W. Longfellow, Oliver Wendell Holmes, Ralph Waldo Emerson, James Russell Lowell, William Cullen Bryant, Bayard Taylor, Nathaniel Hawthorne, Thomas Wentworth Higginson, William D. Howells, Bret Harte, Louise M. Alcott. Among historians, Bancroft, Prescott, Motley and Parkman might be mentioned. Thomas Jefferson was an outspoken advocate of Unitarianism. John Adams and John Q. Adams, Millard Fillmore and William H. Taft are among the men of this faith who have occupied the Presidency of the United States. John Marshall, Charles Sumner and Daniel Webster were also Unitarian laymen. The list is a long one and is referred to only to indicate the character of Unitarianism through the type of men and women who have been identified with it.

Unitarian contributions to hymnology are out of all proportion to the size of the denomination, and the quality of those contributions is second to none. The catholicity of their spirit and the excellence of their devotional and spiritual character are evident from the wide approval which many Unitarian hymns have received. There is hardly a hymnbook of importance which does not contain a number. See HYMNOLOGY.

Bibliography.— The material for this subject is voluminous, particularly on the subject of Unitarian belief. There is no one formal statement which has more authority than another. An excellent presentation is contained in the article by Prof. F. G. Christie in *American Journal of Theology*, 17 Oct. 1918; consult also Savage, Minot J., 'Pillars of the Temple'; Chadwick, John White, 'Old and New Unitarian Belief'; Emerton, Ephraim, 'Unitarian Thought'; Martineau, James, 'The Seat of Authority in Religion'; the sermons and addresses of W. E. Channing, Theodore Parker, R. W. Emerson and M. J. Savage, and pamphlets issued by the American Unitarian Association.

ON THE HISTORY.—Allen, J. H., 'Our Liberal Movement in Theology' and 'The Unitarians' (in 'American Church History' series); Cooke, G. W., 'Unitarianism in America' and 'Unitarianism, Its Origin and History' (American Unitarian Association, 1890); Gordon, A., 'Heads of English Unitarian History'; Eliot, S. A., 'Heralds of the Liberal Faith'; Maury, G. Bonet, 'Early Sources of Unitarian Christianity in England'; and historical pamphlets issued by the American Unitarian Association, Boston, Mass.

CHARLES GRAVES,
Minister of the First Unitarian Congregational Society, Hartford, Conn.

UNITED AMERICAN MECHANICS, Junior Order of, a fraternal and beneficial organization founded in 1853. In 1910 it had a membership of 210,000, with 33 State councils and 2,400 subordinate councils. In the same year the order paid benefits to the amount of $760,000. Its membership is now (1918) slightly increased.

UNITED AMERICAN MECHANICS, Order of, a fraternal and beneficial organization founded in 1845. In 1910 it had a total membership of 46,217, with 18 State councils and 676 subordinate councils. In the same year the order paid benefits amounting to $112,775. It is the parent of the Junior Order.

UNITED ARMENIANS, a branch of the Catholic Church in communion with the See of Rome, but retaining the liturgy and ritual of the ancient Armenian Church; they are estimated to number 150,000 souls. In 1830 Pius VIII nominated a primate for the United Armenians of European Turkey, and as accessions from the Schismatical Armenian Church grew numerous, six suffragan episcopal sees were created 1850. In resentment of the Pope's intervention in the election of their patriarch in 1870 a schism arose and the United Armenian Church lost upward of 4,000 members; the seceders were excom-

municated by the Pope, but they elected a patriarch of their own and came into possession of most of the church property. The schismatical patriarch in 1879 renewed his obedience to Rome, and his example was followed by many of the clergy and people. The United Armenians live in the Balkans and Turkey and in the Ukraine and south Austria.

UNITED BAPTISTS, a religious sect in the United States which had its rise in the middle of the 18th century during the great revival of religion under the ministrations of George Whitefield. Owing to differences of opinion among Baptists as to the methods of the revivalists some of them seceded from the churches and were called Separates, while those who remained were distinguished as Regulars; the Separates approved the "new measures," the Regulars condemned them. After a time some members of both factions came together and took the name of United Baptists. Their articles of belief declared that Christ died to make atonement for sin; that sinners freely choose their condition; that baptism should be administered to believers only, and by immersion; and that foot-washing ought to be practised by all baptized believers. The sect exists chiefly in the southwestern States. In 1917 it had in the United States about 250 ministers, 200 churches and 13,000 communicants.

UNITED BRETHREN, called also **MORAVIANS,** a religious sect or society, the *Unitas Fratrum*, the membership of which was made up at first of Moravians or Bohemians, descendants of the first followers of John Huss (q.v.). A party of Moravians or Hussites, fleeing from persecution in their native countries, were, 1722, permitted by the Count von Zinzendorf (q.v.) to settle on his estate, Berthelsdorf in Saxony. Berthelsdorf, new-named Herrnhut, has ever since been the principal seat of the society; hence the name Herrnhuters by which they are known in Germany. Their patron devoted his whole estate to the propagation of Christianity through the ministrations of the Brethren and was the society's chief director and most zealous missioner and evangelist till his death. In Germany they are recognized by the several governments as Protestants attached to the Confession of Augsburg; but they claim for their bishops apostolic succession through the Waldensian Church; their bishops, however, exercise no jurisdiction, their principal function being that of conferring ministerial order. Every congregation is governed by a board of trustees and a board of elders; the whole society or church is governed by synods composed of bishops and deputies of clergy and laity; in the intervals between synods the affairs of the Unitas Fratrum are managed by a conference of elders. There are communities and settlements of the United Brethren in various Christian countries, as Germany, Holland, Britain, North America and in heathen lands. The Brethren early entered the field of foreign missionary labor, and though numerically the society is not to be compared with the other religious bodies which are represented in that work, it has perhaps the most complete missionary organization in the world. The island of Saint Thomas in the West Indies was the first field of their missionary zeal 1732; the following year they planted a mission in Greenland, the fruits of which have been most abundant; their missionary stations are found also in South Africa, Tibet, Labrador, Alaska and other heathen countries. In 1740 the first communities of the United Brethren were established in Pennsylvania, and in that colony they founded the three towns, Bethlehem, Nazareth and Lititz. From these centres went forth a large number of devoted Christian men and women who labored with great success among the colonists and the various Indian tribes. At present the American province of the Moravian Church or Unitas Fratrum is divided into two districts, the northern district with its seat at Bethlehem, Pa., the southern with its seat at Salem, N. C. Each of these districts has its own synod. In 1917 the Unitas Fratrum or Moravian Church had in the United States 144 ministers, 126 churches and 20,859 communicants. The Union Bohemians and Moravians had in addition for ministers, 21 churches and 1,000 communicants.

UNITED BRETHREN OF CHRIST, a denomination of Evangelical Christians which, though not organized and named till 1800, had its origin in 1766 during a revival of religion among the immigrant German population of Pennsylvania and northern Maryland under the ministrations of Philip William Otterbein, a missionary of the German Reformed Church, and Martin Boehm, a minister of the Mennonite sect. By these leaders preachers were licensed and conferences assembled, but not until 1800 did the movement take the form of a church or assume a distinctive title; in that year at a conference held in Frederick County, Md., the title of United Brethren in Christ was assumed and Otterbein and Boehm were chosen bishops. The sect is in no wise related either to the Unitas Fratrum, though that society is also officially styled United Brethren; nor to Methodism. Otterbein and Boehm were preaching the distinctive doctrines of the United Brethren in Christ before there were any Methodists in this country. The theology of the church is Armenian; its form of worship is simple, marked by congregational singing and participation of all members, male and female, in the devotional exercises. The ministers are appointed to their charges by the bishop and presiding elders at an annual conference; the time limit of the pastoral relation is three years, but may be extended indefinitely by consent of the conference. Since 1889 women are admitted to the ministry on the same terms as men. Originally the religious services were conducted in the German language: at present only in a small number of the churches is that language employed. The church has a theological seminary and a publishing house at Dayton, Ohio, and in other places nine colleges and several academies. Its missionary society conducts home missions, also missions in Germany and in South Africa. In 1917 the number of ministers of this church in the United States was 1,937, of churches 3,577, of communicants 345,705. Through a schism in 1889 the church lost a portion of its membership, and the seceders formed a separate organization called United Brethren (Old Constitution). This body had in 1917 310 ministers, 515 churches and 21,172 communicants, this being a falling off of over 28,000 communicants in seven years. Presumably many of them re-

turned to the parent body, which gained over 60,000 in the same period.

UNITED CHRISTIANS OF SAINT THOMAS, those of the native Christians of Malabar and Travancor who are in communion with the Roman See. The Christian Church of Malabar, called the Church of the Christians of Saint Thomas, dates from an early period, perhaps the 6th century, and appears to have from the beginning been in communion with the patriarch of the Nestorians. At the close of the 16th century, under Portuguese domination, this church was brought into communion with Rome. When the Dutch succeeded the Portuguese, the Christians of Saint Thomas renounced the union with Rome, and receiving a metropolitan from the Jacobite patriarch of Jerusalem, adopted the creed and liturgy of the Monophysites; the direct opposite of their original Nestorianism. Throughout these changes a minority of the Christians of Saint Thomas adhered to Rome, and these, with later secessions from the schismatical Jacobite church, number about 100,000, subject to a vicar-apostolic appointed by the Pope. They use the Syriac liturgy of the Nestorians, not that of the Jacobites.

UNITED COPTS, the small body of seceders from the Monophysite Coptic Church who acknowledge the supremacy of the Pope and are in communion with the See of Rome. The church of the United Copts uses the rite of the Monophysite Coptic Church and retains many of the peculiarities of that church in matters of discipline. The United Copts are presided over by a vicar-apostolic appointed by the Sovereign Pontiff.

UNITED DAUGHTERS OF THE CONFEDERACY, a social, literary, historical, monumental and benevolent association, composed of the widows, wives, mothers, sisters and lineal descendants of men who rendered honorable servic in the army and navy of the Confederate States, or who served in the civil service of the Confederacy, or of any of the States embraced therein, or who gave personal service to the Confederate cause. It was organized at Nashville, Tenn., 10 Sept. 1894, Mrs. M. C. Goodlett, of that city, being the prime mover. In recognition of this service Mrs. Goodlett was subsequently made a permanent official of the organization, with the title of honorary president and founder. The organization has 555 chapters, located in all parts of the United States, and has a total membership of 26,227.

UNITED EVANGELICAL CHURCH, a religious body formed in 1894 by division from the Evangelical Association. The first general conference was held that year at Naperville, Ill., at which the necessary legislation was enacted, and a book of discipline drawn up and adopted. In 1918 the United Evangelical Church had about 1,000 organized congregations, 2 bishops, 550 preachers, 90,000 enrolled members and about an equal number of pupils in Sunday schools. Its mission society maintains missions in Hu-Nan, China; about $100,000 being the annual expenditure of the church for missions. Educational institutions under control of this denomination are Albright College, Meyerstown, Pa., Dallas College and La Creole Academy, Dallas, Ore., and Western Union College at Le Mars, Iowa. It issues *The Evangelical* (weekly), *The Missionary Tidings* and *Die Evangelische Zeitschrift,* all at Harrisburg, Pa. Consult Stapleton, Ammon, 'Annals of the Evangelical Association of North America and History of the United Evangelical Church' (Harrisburg 1900).

UNITED FREE CHURCH METHODISTS, a religious body in Great Britain formed by the amalgamation of two subdivisions of Wesleyanism, namely, The Wesleyan Association which had its rise in 1834 when, upon the removal of one or two influential ministers from the original connection, there resulted a secession; and the Wesleyan Reform Association, another body of seceders from the parent body, in 1849; this secession was caused by the expulsion of several ministers from the Wesleyan Church on charge of insubordination. Soon these two seceding bodies entered into a union as United Free Church Methodists; 40 years after the union of the two bodies the United Methodist Free Church had over 85,000 members, 409 ministers and nearly 3,500 local preachers.

UNITED FREE CHURCH OF SCOTLAND, the name assumed by the ecclesiastical body formed 31 Oct. 1900 by the union of the Free Church of Scotland (q.v.) with the United Presbyterian Church of the same country. The Free Church contributed to the union 1,077 congregations, and the Presbyterians 599 congregations. Three divinity halls (or seminaries) exist, at Glasgow, Aberdeen and Edinburgh.

UNITED GREEKS. See GREEK RELIGION.

UNITED IRISHMEN, a society for political reform founded in Belfast 1794; its aim was to promote union among all the people of Ireland without distinction of creed, for the preservation of their liberties and the extension of their commerce. At that time two-thirds of the people of Ireland, the Catholics, were by law excluded from all participation in the government of their country. The first society of United Irishmen consisted wholly of citizens of Belfast, respectable merchants and professional men, all of them Protestants or Presbyterians. The same year a branch society was formed in Dublin, and soon the Dublin society was recognized as the central directing body. In its membership were comprised many young men representative of the best elements of society — scions of ancient houses Anglo-Irish or Celtic, some prosperous Dublin merchants, and many young professional men who after the misfortunes of 1798 rose to eminent distinction in their own country, in France, or in the United States, without recanting any of the principles of the United Irishmen. At first the society was constitutional and not secret: it was made a secret society in 1795, and steps were taken for the enrolment of men preparatory to a general insurrection when the promised aid in men and material should arrive from France. At the close of 1796 there were reported as enrolled 500,000 men, sworn members of the society, of whom 100,000 were more or less provided with arms — muskets and pikes. In the mean-

time Theobald Wolfe Tone, Arthur O'Connor, Lord Edward Fitzgerald, and other agents of the society had been busy in France, and the Directory had given them assurance that aid would be forthcoming. On 16 Dec. 1796 a fleet of 17 sail of the line, 13 frigates and 13 smaller ships bearing 15,000 French troops sailed for Ireland from Brest, commanded by General Hoche, Grouchy second in command; this expedition, defeated by continuous violent storms, had to return home without effecting a landing in Ireland. In the spring of 1797 adverse winds prevailing for weeks prevented the sailing of a joint expedition of troops of the French and Batavian republics for Ireland. Bonaparte's armée d'Angleterre was made an "army of Egypt" in the spring of 1798, and the long-planned insurrection in Ireland, started without any prospect of aid from France, met with inevitable defeat. After suppression of the insurrection, which was confined to three of the 32 counties, by an armed force of 137,000 men, the chief leaders of the United Irishmen in Dublin and Belfast were first confined in a fortress for four years and then banished; very many of the exiles settled in the United States. Of the 20 leaders confined in Fort George the religious affiliations were: Episcopalians, 10; Presbyterians, 6; Catholics, 4. Though the society was secret the constitution and oath were published. Consult Plowden, 'History of Ireland' (Philadelphia 1806).

UNITED KINGDOM. See GREAT BRITAIN.

UNITED MINE WORKERS OF AMERICA, The, the largest labor union in America, having for its object the union of all mine "employees that produce or handle coal or coke in or around the mines, and to ameliorate their condition by means of conciliation, arbitration or strikes." The National Executive Board levies assessments and orders strikes by a two-thirds vote. This board consists of the president, vice-president and secretary and 29 delegates — one from each district into which the national jurisdiction is divided. Fraternal benefits do not figure largely in this union, which expends most of its revenue in supporting strikes. In most of the great coal regions the union has secured recognition from the operators of the principle of collective bargaining and with the latter fix yearly a scale for the succeeding 12 months. The union was organized 25 Jan. 1890, but it made little headway until the great strike of 1897, in which year its membership for the first time passed the 9,000 mark. Within the last 20 years the membership has grown to 420,000 men, divided into 29 districts and over 3,000 locals. The official organ of the union is the *United Mine Worker* (Indianapolis, weekly). Biennial conventions are held and proceedings published. In November 1917 wages, hours and conditions of labor were regulated by a contract made in Washington, which was to last until 31 March 1920, or "until the expiration of the war."

On 23 Sept. 1919 the United Mine Workers' Convention at Cleveland declared that this contract had expired because of the virtual ending of the war on 11 Nov. 1918. The convention on the same day adopted a resolution demanding an increase of 60 per cent in wages, a six-hour day and a five-day week and authorizing the international officials to call a strike, effective 1 November, if a satisfactory agreement had not been negotiated by that date. On 17 October Secretary Wilson of the Department of Labor conferred with President Lewis of the miners and T. T. Brewster, chairman of the operators' association, in Washington. This conference was futile, as was also a joint conference of miners and operators, called by Secretary Wilson, lasting from 21 to 24 October.

President Wilson issued a statement on 25 October, demanding the recall of the coal-mine strike order and declaring that a "strike under those circumstances is not only unjustifiable, but unlawful." On petition of the government United States Judge Anderson on 31 October issued a temporary restraining order to prevent miners' officials from doing anything in furtherance of the strike. On 8 November a temporary injunction was granted and a mandatory order issued requiring the rescinding of the strike order. Meantime the bituminous miners walked out and production in all union mines ceased. Secretary of Labor Wilson again called the miners and operators to Washington and on 21 November offered as a compromise that an increase of 31 per cent be granted the miners. A few days later, after this had been considered by the Cabinet, Fuel Administrator Garfield proposed an increase of 14 per cent, without any increase in the price of coal to the public. This was rejected by the mine workers.

President Lewis and Secretary-Treasurer Green conferred on 6 December with the Attorney-General of the United States and it was later announced that an agreement had been reached, based on the proposal of President Wilson made on 5 December. Under this plan the miners were to return to work at once; were to receive a 14 per cent increase in wages; after resumption of work the President would appoint a commission of three — one operator, one miner and one representative of the public — to investigate and determine, if possible within 60 days, a basis for a new wage agreement. The miners' representatives after several days' discussion accepted the proposal on 9 Dec. 1919, and on the same day the strike was called off.

UNITED PRESBYTERIAN CHURCH OF NORTH AMERICA. See PRESBYTERIAN CHURCH IN UNITED STATES OF AMERICA.

UNITED PROVINCES OF AGRA (ä'gra) **AND OUDH,** owd (formerly the NORTHWEST PROVINCES and OUDH), British India, a province in the north central part of India, bounded on the north by Tibet and Nepal, on the east by Bengal, on the south by the states of the Central India Agency and on the west by the Rajputana and the Punjab. It consists of Agra (formerly the Northwest Provinces), 83,198 square miles; Oudh, 23,966 square miles; and the native states of Rampur, 899 square miles; and Garhwal, 4,180 square miles. Total area under British administration, 107,164 square miles; grand total, 112,243 square miles. Pop. (1911): Agra, 34,624,040; Oudh, 12,558,004; Rampur, 531,217; Tehri, 300,819; total, British province, 47,182,044; total, including native states, 48,014,080. The city of Agra has 185,449 population. See AGRA; OUDH.

UNITED SECESSION CHURCH. See PRESBYTERIANISM.

UNITED STATES, a federal republic composed of States, Territories, one district and colonies (see BOUNDARIES, ETC.). The official title is "The United States of America." Used in the singular "The United States" is in general acceptance as the name of the country; and its citizens are universally known as "Americans" to the exclusion of all other inhabitants of the Western Continents. The Republic originated in the rebellion of the British colonies of North America, Canada excepted, in 1776, and in the Declaration of Independence the 13 colonies in revolt styled themselves "The Thirteen United States of America." In the present work the order and scope of the articles on the United States are indicated by the following main topics:

1. Boundaries, etc.
2. General Outline History (1776–1920).
3. Causes of the Revolution.
4. The American Revolution (Military Events).
5. The Declaration of Independence.
6. The American Revolution (Diplomatic Conditions during the War and the Peace Negotiations).
7. Articles of Confederation.
8. The Formation of State Constitutions.
9. The Peopling of the United States.
10. Finances (1775–1789).
11. The Federal Convention of 1787.
12. Beginnings of Party Organization and Growth of the Party System and Party Machinery.
13. The Colonial and Territorial Systems.
14. The Cabinet.
15. The Alien and Sedition Laws.
16. The Judiciary.
17. Diplomacy.
18. The War with France.
19. The Louisiana Purchase.
20. Causes of the War of 1812.
21. The War of 1812.
22. Finances (1789–1816).
23. Westward Movement.
24. The New Democracy and the Spoils System.
25. Annexation of Texas.
26. The Abolition and Free Soil Movements.
27. The Mexican War.
28. Slavery.
29. Finances (1816–1861).
30. Efforts to Settle the Slavery Question.
31. Causes of the Civil War.
32. Secession.
33. Military Events of the Civil War.
34. The Confederacy.
35. The Political Events of the Civil War.
36. Finances (1861–1919).
37. Reconstruction.
38. The Thirteenth, Fourteenth and Fifteenth Amendments to the Constitution.
39. The War with Spain.
40. Territorial Expansion.
41. State Constitutions.
42. Immigration (1789–1916).
43. Suffrage.
44. Civil and Religious Liberty.
45. Disputed Elections.
46. Impeachment.
47. The President's Office.
48. The Vice-Presidency.
49. Speaker of the House of Representatives.
50. History of Arbitration.
51. Growth and Development of Law.
52. Railroad Transportation.
53. Foreign Commerce.
54. Industrial and Commercial Development.
55. Army of the United States.
56. Navy of the United States.
57. Chronological History of the United States Navy.
58. Political Parties.
59. Foreign Policy.
60. The United States and the European War.

Appended to these articles will be found adequate cross references to much material which has been singled out for more extensive treatment under separate headings.

1. BOUNDARIES, ETC. The main portion of the United States occupies the middle part of North America extending approximately from 24° 20′ to 49° north latitude, and from 66° 48′ to 124° 32′ west longitude. The northern boundary line beginning with the Pacific Ocean is as follows: The fixed line running about southeast in the Strait of Juan de Fuca, midway between the State of Washington and Vancouver Island, to Puget Sound, then north, and northeast, to the Strait of Georgia, then northwest to the 49th parallel; from thence east to the Lake of the Woods; thence along the southern coast of the Lake of the Woods, continuing along Rainy River, through the middle of Rainy Lake, and several other lakes which are expansions of Rainy River, to Lake Superior, north on the northwestern coast of Lake Superior to Port Arthur. From Port Arthur the line continues east through the Great Lakes (except Michigan) and the rivers or straits connecting them, to the Saint Lawrence River; thence about midway to the 45th parallel; thence along the 45th parallel east to Hall's Stream; thence north by east, along Hall's Stream nearly to the 46th parallel; then an irregular highland boundary to the Maine State line; thence along highland lines and the southwest branch of the Saint John River to 46° 45′; thence north 47° 20′; thence northwest to the extreme northerly boundary of Maine. From this point the boundary is along several small lakes and streams tributary to the Saint John; thence along the Saint John to the New Brunswick boundary and south in a straight line to the head of Saint Croix River; thence along the Saint Croix River, Grand Lakes and through Passamaquoddy Bay to the Atlantic Ocean. The southern boundary line between the United States and Mexico is as follows: Beginning at the point on the Pacific Coast at 32° it extends east to the Colorado River, south 20 miles along the Colorado, southeast to 31° 20′ north latitude and 111° west longitude, east along the line of 31° 20′ for 160 miles; thence north to latitude 31° 47′; thence east to the Rio Grande, and along the Rio Grande southeast, east and southwest to the Gulf of Mexico. The remaining portion of the southern boundary is defined by the northern and eastern shore line of the Gulf of Mexico; the eastern boundary by the Atlantic Ocean and the western boundary by the Pacific Ocean. The Canadian boundary line is 3,900 miles long; the Mexican boundary line is 1,975 miles long, and the total ocean, lake and river boundary is 10,758 miles. The greatest length, from the Atlantic to the Pacific, is 3,100 miles and north and south 1,780 miles. Alaska (q.v.), in the northern part of North America; Hawaii (q.v.), in the Pacific Ocean; Porto Rico (q.v.) and the Virgin Islands in the Atlantic Ocean; the Philippines (q.v.), and several small islands in the Pacific (parts of the eastern hemisphere), are all included within the United States. The area of the main portion of the United States is 3,026,789 square miles. The area of Alaska is 590,884 square miles; of the Philippines 115,026; Porto Rico, 3,604; Hawaii, 6,449; Panama Canal Zone (leased), 436; Virgin Islands, 149; Tutuila and Samoa, 55; Guam, 210; making a total of 3,743,518 square miles.

Coast Lines.— The coast line is comparatively regular; there are no large indentations, but the largest and most numerous are on the Atlantic Coast. The principal arms of the sea on the Atlantic are Chesapeake, Delaware, New York, Massachusetts and Cape Cod bays, and Long Island, Albemarle and Pamlico sounds. On the coast of the Gulf of Mexico are Mobile, Galveston and Tampa bays; and on the Pacific Coast San Francisco Bay, Bay of Monterey, Puget Sound and Santa Barbara and San Pedro channels. (For coast lines of Alaska and the island possessions see articles on ALASKA; GUAM; HAWAII; PANAMA CANAL; SAMOA; VIRGIN ISLANDS, etc.). There are no large islands off the coast of the main portion of the United States. Long Island (q.v.) is the largest; the next important are the islands off the northeast Atlantic Coast and

the Santa Barbara (q.v.) group off the southwest Pacific Coast. Florida in the southeast is the largest peninsula. There are more good harbors on the Atlantic Coast than on the Pacific or Gulf coasts. The Atlantic Coast differs widely in character in the north and south. In Maine, New Hampshire and northern Massachusetts it is very rocky, with rocky headlands jutting far into the sea and with numerous rocky islets. From Boston southward the coast is low and sandy, with numerous sandbars, back of which are swamps and lagoons. The latter is especially true of the North Carolina and Virginia coasts. The Dismal Swamp is the largest depression of this kind. The rivers of this coast have tidal estuaries. The Gulf Coast is also low and sandy and in places extremely dangerous to navigation because of sandbars. The character of the Pacific Coast is very simple, there being an almost straight unbroken front to the sea throughout its length. With its indentations the Atlantic Coast line has an estimated total length of 12,350 miles; the Gulf Coast, 5,725 miles, and the Pacific Coast, 3,250 miles.

Topography.— The main part of the United States presents four physical divisions: two elevated and two lowland regions. The elevated are the Appalachian Mountains (q.v.) in the east and the Rocky Mountains (q.v.) or Cordilleran system in the west. The eastern lowland mass is along the Atlantic Coast, broad at the Gulf of Mexico and narrowing toward the north where the mountains are but a short distance from the ocean. The southern part of the Atlantic lowlands joins the central lowland region south of the Appalachian Mountains and about 70 miles from the Gulf of Mexico. It is much less in extent than the central lowland division but it contains a large population, is the oldest portion settled by Europeans and was the chief battle ground in the war for American independence. The northern and southern parts of this lowland section differ materially in formation and soil. The mountains in the northern part approach the ocean so that the foot-hills are almost at the sea line; the lowlands are in some places really series of low hills, masses of rocks, sandy soil, large areas covered deep with glacial deposits and with masses of rock formation which show the marks of mighty ice-forces. Beginning with and including the southern portions of New Jersey, and continuing to the Gulf and Florida Strait, is a plain of low, almost level, land, extending in a gradual slope from the mountains to tide water. The soil and climate contribute to the extensive growth of fruits, tobacco, corn and cotton. The northern section of the Atlantic lowland is a worn-down mountain region and the southern section at no ancient period was sea-bottom and even now the line of demarcation between the coastal plain and the continental shelf is very slight in many places. This section has received the name of "Tide Water Country," on account of its being a gift to the continent from the sea, and also because many of its rivers are tidal streams for some distance from the ocean. The central lowland lies between and on the lower slopes of the two great uplifts. It is called the Mississippi Valley on account of the greater portion being in the basin of the Mississippi River. The higher slopes, merging into the foot-hill reglon of the Appalachian on the east and the Pacific on the west, become the plateau lands. The so-called Piedmont Plateau lies west and northwest of the central part of the great Atlantic lowlands or plains. The whole plateau seems not to have been brought down to the level of the sea, but to have inclined slightly to seaward and toward the valleys of the streams; so that, in reference to its plain condition, the region is often called a peneplain. When the land portions of the Atlantic lowland was raised above sea-level the same system of upheaval extended throughout the Piedmont region, and has continued with intermission to the present time, until the old plains have now reached an altitude which constitutes them a plateau as now understood. The plateau is bounded on the northwest by the Appalachian Mountains. It was not upheaved evenly and simultaneously in all its parts. Where first lifted, the gorges and valleys are convex; where last lifted they have concave profiles. The large grassy, almost treeless areas in this section are called prairies. This great lowland region of the United States is a part of the central lowland section of North America, which is called, in Canada, the Hudson Bay and Mackenzie regions. In the southern part of this section are vast areas of flood plains, and also land which at no very remote period was wholly under water. Beginning with the Atlantic plain or lowland at Florida, extending west and including the southern part of the central lowland section, there are broad areas only a few feet above sea-level, in many places less than 100 feet. The northern part of this central section is bounded by the Great Lakes. The divide between the streams that flow into the Great Lakes and those which flow into the Gulf of Mexico, by way of the Mississippi, is very slight. The three long slopes in this division are the one from the northern part to the Gulf; the one from the Appalachian divide on the east to the Mississippi; and the third from the Rocky Mountain divide on the west to the Mississippi. There are numerous sandbars and swamp lands along the southern coast. The eastern slope is shorter and less steep as a whole than the western slope. There are high bluffs along many of the rivers of the western part, even in sections where there are large areas of rolling prairie lands. The huge boulders and mountain peaks of the northwest section seem like outposts on the beginning of the plateau region. In the southwest the lowlands extend around the southern part of many of the mountain chains, so that the greater part of the United States south of the low rocky hills which form the extremity of the Appalachian Mountains, and extending west to the Guadalupe Mountains, is one continuous lowland mass. The mountains in Missouri and Arkansas, south of the Missouri River and just west of the Mississippi, are the most important highlands in this whole section. In Missouri these highlands are called Ozark Mountains or Ozark Plateau, in Arkansas Ouachita Mountains.

Along the Pacific Coast is a narrow strip of low land of not sufficient extent to be classed among the great physical divisions, but of great value from an economic point of view. The southern part of this lowland border is considerably wider than that of the northern part.

The numerous parallel valleys, in some places valley arms, which are on the eastern border of the Pacific lowland strip, furnish a considerable area of productive farm lands.

The eastern uplift, the Appalachian Mountains, are the older and less extensive of the two great highland sections of the United States. (See APPALACHIAN MOUNTAINS). They consist chiefly of mountain ranges which are nearly parallel with the Atlantic Coast and extend from near the Gulf of Mexico north into Canada. Nearly all of the western part of the United States, beginning about the 104th meridian, belongs to the Rocky Mountain region. (See ROCKY MOUNTAINS). This portion of the United States has a greater altitude and extent than the mountain lands of the Atlantic region. The Rocky Mountains extend from Mexico to Canada. The ranges which constitute this group are by no means as regular in arrangement as are the Appalachian chains; some extend nearly parallel with the coast; many lofty ranges are at almost right angles with the north and south ranges and others run northeast and southwest. Enclosed by ranges of these mountains are the Great Basin (q.v.) and the Yellowstone Park (q.v.). The Great Basin region is a series of basins isolated to all appearances from each other so far as drainage lines, and differing in soil and geological formation. The chief basins are the Carson, Humboldt and Great Salt Lake. The mountain ranges within the Great Basin trend mostly north and south. The vast area of the volcanic region of the Rocky Mountains contains many extinct volcanoes. On both the eastern and western border are numerous high peaks connected by high plateaus. In the southern part or the portion drained by the Colorado River is a region of high plateaus crossed by streams which flow through deep cañons, some of which are over 2,000 feet deep. The Grand Canyon (q.v.) of the Colorado is in places 6,000 feet deep.

Hydrography.— The United States may be divided into four great drainage slopes,— the Atlantic, Great Lake, Gulf and Pacific — although the second and third of these belong broadly speaking to the Atlantic. All the streams of the Atlantic slope drain into that ocean by river mouths within the territory of the United States. All the streams of the Great Lake slope ultimately discharge into the Saint Lawrence River, also within the territorial limits of the United States. The Gulf slope includes all of that part of the United States which drains into the Gulf of Mexico. In popular usage, most of this is called the valley of the Mississippi, while small areas are drained into the Gulf by streams not tributary to the great river. East of the Mississippi this slope is drained by the Apalachicola, Mobile and Pearl, and to the west by the Sabine, Brazos, Colorado, San Antonio, Nueces and Rio Grande. Along the western border of the Gulf slope the country is arid, having a rainfall of less than 20 inches annually. In this arid region there are many small streams whose waters are not carried away by ocean-feeding rivers, as the small streams are lost in the sands. On the Pacific slope all streams that ultimately reach the sea do so within the territorial limits of the United States, but the district drained by the Colorado River of the West reaches the Gulf of California by passing a short distance through Mexican territory. In a large part of the Pacific slope there are many small streams that discharge their waters into sands, where they are evaporated and lost from the ocean-reaching drainage; but the valleys in which they are evaporated incline toward streams draining into the Pacific Ocean. We thus have an Atlantic slope, a Great Lake slope, a Gulf slope and a Pacific slope. The lines of demarcation between these slopes are very irregular. Between the Atlantic and the Great Lake slopes the divides are sometimes in mountains and sometimes in hills; between the Atlantic and Gulf the divides are in part in mountains and in part along the low ridge of Florida; between the Gulf and Great Lake slopes the divide is an inconspicuous elevation, so low in many places that the waters may easily be diverted from one slope to another. The divide between the Mississippi region and the Pacific region is sometimes mountains, with peaks from 8,000 to 14,000 feet above sea-level. Of the large river systems the chief are the Mississippi, the Saint Lawrence, the Columbia and the Colorado. The Mississippi (q.v.) is the largest, including within its basin nearly all the region in the central lowland section, and a large area of the Rocky and Appalachian Mountains. The chief tributary is the Missouri (q.v.) which has a drainage area of about 530,000 square miles. Next in drainage area is the Ohio River (q.v.), the basin of which is over 200,000 square miles; the Arkansas, 185,671 square miles; the Red River, nearly 90,000 square miles. The total area drained by the Mississippi, its tributaries, and other streams which enter the Gulf, is 1,726,000 square miles. The Rio Grande, which also enters the Gulf of Mexico, has one large tributary, the Pecos. Further streams which flow into the Gulf of Mexico are the small Colorado, the Brazos and others in Texas, and several rivers in Mississipni, Alabama and Georgia. The Mississippi and its tributaries are navigable for thousands of miles. To the great central waterways is due the early development of the interior of the United States, first as a section with trading posts and forts at convenient places on the navigable streams, and later as a farming and manufacturing region. West of the divide in the Rocky Mountains the drainage is to the Pacific Ocean. Nearly all the rivers, except those in the Great Basin, flow directly, or through a main stream to the open sea. The Colorado River enters the Pacific Ocean through the Gulf of California. The largest river of the Pacific Basin is the Columbia (q.v.). Some of the other important rivers are the Sacramento, San Joaquin, Klamath and a number of short streams. The rivers in California and some of the other valleys follow the course of the valleys, but the Columbia, Colorado and branches of the Columbia break through the mountains in several places and thus form high waterfalls and series of cascades. The Columbia has several large tributaries, chief of which is the Snake River. The rivers of the Atlantic Basin east of the Appalachians have mostly rapid currents, and have had great influence in the development of the manufacturing industries of the country. Many of the streams which flow into the Atlantic, or into wide bays which are arms of the ocean, are tidal streams for some distance

inland. (See DELAWARE; HUDSON, etc.). The principal rivers of this basin are the Kennebec, Merrimac, Penobscot and Manchester in the northeast; the Connecticut, which flows into Long Island Sound; the Housatonic, the Hudson, a magnificent stream, alike remarkable for its scenery and its navigable importance, which flows south for 300 miles and contributes to form the harbor of New York; the Delaware, which after a course of 300 miles enters the Delaware Bay and is navigable for large steamers to Philadelphia, a distance of 40 miles; the Potomac, which flows into Chesapeake Bay, and is navigable for the largest vessels to Washington, a distance, including the bay, of 200 miles; and the Savannah, which enters Savannah Bay and is navigable for large vessels for 17 miles, to the city of Savannah, where it forms an important harbor. Besides the rivers, one of the most remarkable features of the United States, as also of Canada, is the chain of large fresh water lakes: Superior, Michigan, Huron, Erie and Ontario. The lakes drain an area of about 90,000 square miles, and send their waters into the Saint Lawrence, after precipitating the greater part of them in an accumulated mass over the renowned Falls of Niagara (q.v.), which are between Erie and Ontario. The rivers of the United States which flow into the Great Lakes (q.v.) are of no great length. The chief streams are the rivers of northern New York and Vermont, some of which enter the Saint Lawrence River through Lake Champlain; the Genesee River in the west central part of New York, and a number of small streams which enter Lakes Erie, Huron, Michigan and Superior. (See SAINT LAWRENCE RIVER). The Red River of the North enters the Atlantic Ocean through Lake Winnipeg and the Hudson Bay. In the interior of the United States are many groups of small lakes which have been mentioned in articles on the different States. The inland seas or salt-water lakes within the Great Basin are of special interest as being the remnants of large inland seas. The fresh-water lakes in the Appalachian section, and even the Great Lakes, were once much larger than at present. The chief characteristics of the whole drainage system of the United States are that by far the greatest portion of the waters are carried south or in a southern direction, and reach the Atlantic Ocean through the Gulf of Mexico. The Great Lakes with their large outlet, the Saint Lawrence River, receive but a small portion of the drainage; their chief supply comes from the melting snows of the Rocky Mountains. The rivers which enter the Pacific are small streams, except the Columbia and Colorado. The Red River of the North is the largest stream which flows north.

Climate.— The main land-mass of the United States is in the temperate zone, and the climatic conditions of the whole country are about what is general in such zones modified chiefly by the great mountains and the winds. With every variation of surface it possesses every variety of climate, from that of the tropics to that of the Arctic regions. It is at the same time one of the hottest and one of the coldest countries; one of the wettest and one of the driest. The prevailing winds are from the west and are an important factor in the climatic conditions. The circulations of air from west to east does not take place in steadily blowing winds, as is the case with the trades, but in cyclonic or whirling storms that have a general easterly movement alternating with anticyclonic movements of a similar character. In these storms winds blow from all directions, the general course being nearly toward the centre of the storm. There is another class of storms which occur not infrequently, although they do not form part of the regular air circulation. This is what is commonly known as the West Indian hurricane, very violent and of a much more intense type than the ordinary cyclone of temperate latitudes. Originating in the tropics, their course is generally over the West Indies, entering the United States on the Gulf Coast and working off to sea in a northeasterly direction. Many of these have been extremely disastrous. The average annual temperature of the extreme southern part is 75° F. and of the extreme north 45°. The average temperature for January in the extreme north (exclusive of Alaska) is about 20°; for July about 60°. The mercury falls as low as 40° below zero in the northern part of Minnesota, and is sometimes as high as 120° in the hot, dry sections of Arizona and Texas. The west winds, which are prevalent in January, and which sweep over large interior areas lower the temperature, frequently to the minimum. The difference in temperature of places in the same latitude on the Atlantic and Pacific Coast is quite marked. That of the Pacific is much warmer than that of the Atlantic. The rainfall is generally the greatest in Washington, Oregon and Florida, but the humidity is great in the southern portion of Louisiana and other places along the Gulf Coast. The region around the Great Lakes has not an excessive humidity; but it is subject to extreme and rapid changes in temperature. This region is also subject to extreme changes in the winds. The Mississippi Valley receives its rainfall almost entirely from the Gulf while the Atlantic States are supplied from the Atlantic Ocean. It is estimated that the Gulf supplies fully 55 per cent of the total rainfall in continental United States, the Pacific Ocean 30 per cent and the Atlantic 15 per cent. See AMERICA — CLIMATIC CONDITIONS; RAINFALL.

Flora.— The wide range of soil, topography and climate give the United States a rich and varied flora. Tropic species are found in Florida, California, Texas, New Mexico and Arizona, along the southern frontier, while along the Canadian border boreal species abound. In the greater part of the country, as might easily be inferred from its geographical situation, the species are those of the north temperate zone and to a large extent are peculiar to North America. (See AMERICA — FLORA). The whole number of indigenous species, exclusive of the lower cryptograms, probably amounts to 5,000, and of these many have a very wide range. The number of woody species is about 850, and about half of these are of a size to be called trees. Of the larger and more important, excluding all the smaller ones, and also the tropical species of the southern border States, there are about 150 species which are of economic importance. About 50 of these belong to the Coniferæ. This coniferous growth extends in enormous

volume down the cool, wet Pacific slope to central California; the giant redwoods and sugar-pines, etc., and the huge sequoia, the largest and oldest plants on the earth, being famous everywhere. The conifers abound also through Michigan, Wisconsin and Minnesota to southern Missouri and northwestern Arkansas and to northeastern Texas and Oklahoma. The hickories, sequoias, magnolias, sassafras, etc., so abundant in America are only found in fossil form in the Old World. Many valuable varieties of grasses have originated from native species. Near the Atlantic Coast and along the southern borders European explorers found maize, squashes, tobacco and other useful plants in cultivation among the aborigines. Central United States has prominent deciduous (hardwood) trees, such as the oak of many varieties, the beech, maple, elm, chestnut, black walnut, hickory, ironwood, pepperage, red mulberry, etc. In the Southern States the yellow pine holds foremost place. The characteristic forms in the South are the magnolia, palmetto, tulip-tree, plant-tree, pecan, etc., with the cypress everywhere in the swampy regions. The plains are treeless, except a narrow belt along the water courses, and are covered with grasses, grading in the more arid regions into artemesias and cacti. The Cordilleran woods are chiefly conifers on the mountains; on the plains and in the valleys are the yuccas, cactus, etc., as stated above, and whose dense thorny growth is termed chaparral. In the Appalachian Mountains and the upper Mississippi Valley, broad-leaved, deciduous trees, oaks, chestnuts, walnuts, poplars and cherry predominate; and in the Great Lake region pines, firs, spruces and larches are most abundant. The timber trees are considered elsewhere under their own heads, oak, ash, etc. (qq.v.), also under LUMBER INDUSTRY OF THE UNITED STATES; FORESTRY. Other economic products of the native flora fall naturally into the classes of fruits, nuts and forage grasses. The native nuts include pecans, walnuts, chestnuts and pine nuts. The fruits include wild raspberries, blackberries, blueberries, elderberries, cranberries and serviceberry. The principal varieties of grasses are Kentucky blue grass, grama grass, bunch grass, buffalo grass, the clovers, lupine and white sage. To these must be added the hundreds of plants of all sorts from fungi to trees which have been introduced since the white settlement. Some are of economic value while others are among our most noxious and troublesome weeds. The white daisy is one of the latter as also the buttercup, dandelion, chickory and thistle. Chinese, Japanese and Mexican species have been introduced with success in California. The eucalyptus, several species of palms, English walnut, olive, prune, almond, etc., are now grown successfully.

JOHN B. MCDONNELL,
Editorial Staff of The Americana.

Geology.— There is great diversity in the geology of the country, a diversity that extends to the constituent rock formations, their distribution, structural arrangements and contained mineral deposits. Every important rock system is represented in its stratigraphy by one or more members. The basal formations belong to the early Pre-Cambrian and consist of ancient igneous rocks, like granite and various lavas, with highly metamorphosed sediments in the form of crystalline limestones, schists and quartzites. Such occur along the axis of the Appalachians from New England into Alabama, and in the Black Hills, Ozarks and Rocky Mountains; they are also developed on a larger scale in the Adirondacks and in the Lake Superior district, where they constitute outlying areas of the so-called "Laurentian shield" of Canada which has a surface of 2,000,000 square miles. These rocks are particularly rich in iron ores, but yield also various other valuable minerals. In the Lake Superior district the Keweenawawan beds of sandstones and intercalated lavas mark the closing stages of Pre-Cambrian time; they attain an estimated thickness of 40,000 feet and are the sources of the great deposits of native copper that occur on Keweenaw Peninsula of Upper Michigan.

A long period of time elapsed in most places after the Pre-Cambrian until the first deposits of the Paleozoic group were formed, the hiatus being marked by a strong unconformity caused by erosion. The ensuing Cambrian strata rest upon the eroded and more or less upturned Pre-Cambrian rocks and are generally to be distinguished by their less altered condition and wealth of fossils. The Cambrian, Ordovician and Silurian strata, the older members of the Paleozoic group, spread over extensive areas in the eastern United States, lying along the borders of the crystallines in successive overlapping series. Altogether they have here a thickness probably of seven or eight miles, mainly sandstones, shales and limestones. In the west they occur in smaller belts and isolated patches. The valuable minerals are oil and gas in the Ordovician and Silurian, salt in the Silurian and iron ore represented by the beds of Clinton hematite which extend from central New York in interrupted outcrops all the way to northern Alabama.

The succeeding members of the Paleozoic included in the Devonian and Carboniferous systems are largely sediments that accumulated in great thickness in the Appalachian belt and west as far as the Mississippi Valley, also to a lesser extent in the Rocky Mountain and Great Basin regions. Oil, gas and coal abound in these strata, the Carboniferous being a great coal-making period the world over. With the close of Carboniferous time a great change took place in the eastern part of the country, by which the sediments along the Appalachian region were uplifted from the sea and folded into mountains, which have ever since remained as a highland.

The Mesozoic strata are usually grouped into the Triassic, Jurassic and Cretaceous systems. A belt of Triassic rocks parallels the Atlantic Coast from North Carolina to New England. Sandstones, shales and trap are the chief rocks, the Palisades of the Hudson exemplifying one of the exposures of Triassic trap, a basic volcanic rock. Extensive exposures of Triassic strata are met with in the western interior, where they seem to have been accumulated in shallow lakes and as wind deposits. Jurassic rocks are limited in development mostly to the Pacific Coast. The Cretaceous was a period of extensive sedimentation, and its rocks spread in a wide belt from the Gulf of Mexico northward across the central United States and Canada to the Arctic Ocean. A thickness of four or five miles is attained by the sediments in the

Rocky Mountain region. Valuable coal measures accompany the beds, second in importance only to those of the Carboniferous. Oil and gas also are found in the Cretaceous strata. Two mountain systems had their beginnings in Mesozoic time: the Sierra Nevadas were reraised in late Jurassic and the Rockies at the end of the Cretaceous period.

The Tertiary formations, which comprehend the greater part of the Cenozoic group, are spread in discontinuous patches over the western United States and in a long belt that stretches along the southern Atlantic Coast and the Gulf region, reaching up the Mississippi Valley to the Ohio River. Some important coal beds of lignitic character were deposited in the interior during the early Tertiary. The strata otherwise include sandstones, shales, soft limestones and unconsolidated detrital materials. The later Quaternary deposits are largely represented by glacial accumulations from the ice-sheets that extended from the highlands of Canada into the northern part of the county; on melting the ice left behind a mantle of sands, gravels and clays, here and there heaped up into hillocks (kames, drumlins, eskers, etc.), that lie over all of the other formations. To the south of the limits of ice advance, which did not reach below the Ohio River, stream and estuary deposits were formed at this time and on the uplands the finely divided, probably wind-blown material called "loess." At the outset of the ice invasion the land surface was considerably higher than at present and the northeastern coast line no doubt extended 100 miles or more further out into the Atlantic, to the limits of the continental shelf. This elevation and increase of land area thus indicated were influential in producing the glacial climate, although not the only factors concerned with it. At the close of the Glacial epoch a subsidence took place, causing the sea to advance upon the land and producing fiords and drowned valleys along the coast, as now in evidence.
